Caution: Deep needling may penetrate a full bladder.

See Figure 8-28 to examine structures within reach of a deeply placed acupuncture needle. Note as well how the degree of adipose tissue present in the caudal abdomen changes safe needling depth.[2]

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: An epigastric artery rupture or rectus abdominis muscle tear can create a hematoma in the rectus sheath. Once considered rare, rectus sheath hematomata are increasing in frequency and severity.[3] More patients are receiving anti-coagulant medications and the population as a whole is advancing in age. Typically but not exclusively, the patient is an elderly female with acute onset of abdominal pain; examination reveals a palpable mass associated with a history of trauma to the abdomen. Missing this diagnosis may lead to unnecessary surgery for a false acute abdomen. In addition, incising the abdominal wall could exacerbate the bleeding by eliminating the natural tamponade the rectus sheath provides, leading to uncontrolled hemorrhage.

The consequences of rectus sheath hematoma range from self-limiting disease to patient demise. Delaying proper treatment could allow a small, initially asymptomatic mass to enlarge and cause signs of pelvic irritation accompanied by mild pyrexia and leukocytosis. Patients experiencing extensive hemorrhage into the rectus sheath exhibit tachycardia, tachypnea, sweating, and related signs of low blood volume.

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[4]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture.[5] About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the

patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation. The rectus abdominis muscle consists of a cranial and caudal portion demarcated by the arcuate line, landing about 5 cm caudal to the umbilicus. Transverse tendinous inscriptions or intersections further divide the muscle into segments, as illustrated through semi-transparent skin in Figures 8-24 and 8-27.
- **Pyramidalis muscle:** An inconstant muscle with varying incidence. Estimates of its presence in humans range from 3%[6] to 30%[7] or more. This triangular muscle resides cranial to the rectus abdominis muscle. It attaches to the pubis and the cranial pubic ligament, inserting onto the linea alba approximately halfway between the pubic symphysis and the umbilicus. It helps tense the linea alba when present.

Clinical Relevance: Caudal to the arcuate line of the abdomen, the rectus abdominis loses the protection its deep wall enjoyed cranial to the line. That is, the caudal aspect of the rectus sheath thins in this section of the abdomen as the connective tissue contribution of the obliques and the transversalis muscle dwindles. Thus, only a weak transversalis fascia and peritoneum separate the muscle from the abdominal compartment. This fact raises safety concerns for acupuncturists treating caudal abdominal acupuncture points along the CV, KI, ST, and SP lines, because deep needling carries more risk of entering the abdomen. Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress. In the caudal abdomen at KI 12, trigger points can incite feelings of bladder irritation and discomfort.

The pyramidalis muscle, when present but dysfunctional, refers pain to the umbilicus.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** These nerves innervate the anterior abdominal muscles and their overlying skin, as well as the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior, or caudal, to the umbilicus. Entrapment of these nerves within the rectus abdominis muscle causes rectus abdominis syndrome, leading to lower abdominal and pelvic pain that, in female patients, simulates pain from gynecologic conditions. More details about the subcostal, iliohypogastric, and ilioinguinal nerves follow.
- **Subcostal nerve (T12):** Supplies the skin in the region.

- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3[8]):** The iliohypogastric nerve divides into anterior and lateral cutaneous branches. The lateral branch supplies the skin over the iliac crest while the ventral branch supplies the skin cranial to the pubic region.

The iliohypogastric nerve is the first nerve of the lumbar plexus.[9] The lumbar plexus is formed from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or caudal to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.

The iliohypogastric nerve communicates extensively with the subcostal and ilioinguinal nerves. The iliohypogastric nerve pierces the transversus abdominis muscle. Some of its branches pierce the aponeurosis of the external oblique muscle. Communication between the genitofemoral and ilioinguinal or iliohypogastric nerves is common, causing overlap of sensory supply. Neurons from T11-L2 travel to the pelvic plexus via the inferior mesenteric plexus and hypogastric nerves.[10] Within the pelvic plexus, synapses take place between the plexus and postganglionic sympathetic fibers that project to the penis. Postganglionic sympathetic fibers consist of two types: cholinergic sympathetic and adrenergic sympathetic neurons. The cholinergic neurons function as vasodilators to the erectile tissue of the penis. Adrenergic neurons activate smooth muscle tissue in the epididymis, vas deferens, seminal vesicles, and prostate gland.

- **Ilioinguinal nerve (L1, occasionally with T12):** Branches from the ilioinguinal nerve supply the skin of the scrotum and labium majus by means of its anterior scrotal and labial branches, respectively. Other branches supply the skin over the proximal and medial thigh. The ilioinguinal nerve accompanies the spermatic cord or round ligament of the uterus as it moves through the superficial inguinal ring, on the way to its destination of either the scrotum or labium majus, depending on the gender of the individual. The ilioinguinal nerve is involved in the afferent limb of the cremasteric reflex, along with the genitofemoral nerve (L1,L2). Branches of the ilioinguinal nerve include the anterior scrotal in males and the labial in females. Damage to the ilioinguinal nerve has been called an "infamous complication of inguinal hernia surgery".[11]
- **Nerve to the pyramidalis muscle (T12 – L2, variable segmental supply):** The pyramidalis receives innervation from branches of the lumbar plexus described as "border nerves" where the abdominal wall abuts the pelvic limbs. Nerves supplying this territory include the iliohypogastric, ilioinguinal, and genitofemoral nerves. The nerve to the pyramidalis exhibits wide variation in its origin, arising potentially from any of the three nerves.[12]
- **Spermatic ganglion:** Connected to the caudal (inferior) mesenteric plexus, likely sympathetic, supplying, at least in part, the testicular artery.[13]

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[14] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from the plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively. The variability in spinal nerve origins for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy.

Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually cause changes in several spinal cord segments rather than only one level, which works toward the acupuncturist's advantage by distributing the neuromodulation to a broader territory.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[15] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[16] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[17] Paresis of the abdominal wall may cause large swelling and mechanical complaints. Considering the benefits of acupuncture and related techniques for peripheral nerve injury, ilioinguinal nerve injury would likely respond to neuromodulation unless the nerves were severed completely. Chronic pain syndromes that take hold following iliohypogastric or ilioinguinal nerve injury during open inguinal hernia repair or gynecologic surgery should also be addressed with neuromodulation, in addition to adjunctive abdominal support and multimodal analgesia.

Vessels

- **Superficial (inferior) epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior (deep) epigastric artery:** Supplies the rectus abdominis muscle and the medial portion of the anterolateral abdominal wall. A branch of the external iliac artery. Anastomoses with the superior epigastric artery within the rectus sheath near the umbilicus.
- **Superficial (inferior) epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior (deep) epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins,

act as collateral routes for abdominopelvic blood return to the heart. Collateral venous connections provide alternate routes for venous return from the lower extremities, by bypassing an obstructed or ligated inferior vena cava. Venous blood instead drains into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.

- **Superficial external pudendal artery:** A branch of the femoral artery, the superficial external pudendal artery crosses the spermatic cord and supplies the skin on the lower abdomen, the penis, and scrotum. The superficial external pudendal artery anastomoses with branches of the internal pudendal artery. The deep external pudendal artery also arises from the femoral artery, but in contrast to its superficial counterpart, passes across the pectineus and adductor longus muscles to supply the skin of the scrotum and perineum. The deep external pudendal artery anastomoses with scrotal branches of the perineal artery.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; around the umbilicus, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep face. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[18] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[19]

Indications and Potential Point Combinations

- **Urogenital disorders and pain:** KI 12, SP 6, PC 6, BL 23, BL 25, BL 32, CV 3, GV 3.

Evidence-Based Application

- A case series reported that both acupuncture and moxibustion at BL 23, BL 32, BL 54, SP 6, CV 3, CV 4, KI 12, and LR 3 were effective in treating **erectile dysfunction**.[1]

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: An epigastric artery rupture or rectus abdominis muscle tear can create a hematoma in the rectus sheath. Once considered rare, rectus sheath hematomata are increasing in frequency and severity.[2] More patients are receiving anti-coagulant medications and the population as a whole is advancing in age. Typically but not exclusively, the patient is an elderly female with acute onset of abdominal pain; examination reveals a palpable mass associated with a history of trauma to the abdomen. Missing this diagnosis may lead to unnecessary surgery for a false acute abdomen. In addition, incising the abdominal wall could exacerbate the bleeding by eliminating the natural tamponade the rectus sheath provides, leading to uncontrolled hemorrhage.

The consequences of rectus sheath hematoma range from self-limiting disease to patient demise. Delaying proper treatment could allow a small, initially asymptomatic mass to enlarge and cause signs of abdominopelvic irritation accompanied by mild pyrexia and leukocytosis. Patients experiencing extensive hemorrhage into the rectus sheath exhibit tachycardia, tachypnea, sweating, and related signs of low blood volume.

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[3]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture.[4] About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated

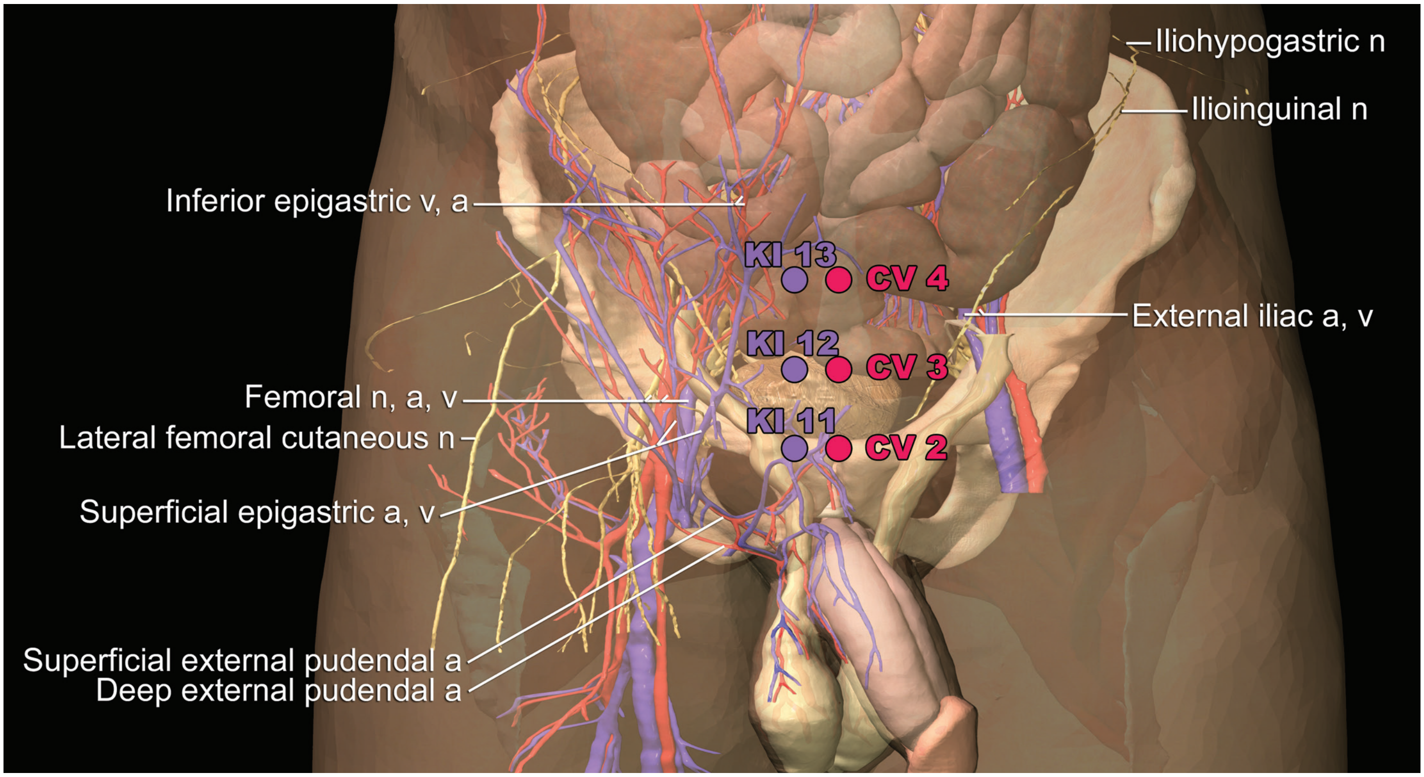

Figure 8-29. KI 13, known as the "Qi Cave" or "Qi Hole", partners with CV 4, the storage site for "original Qi". In females, CV 4 pertains to the uterus, the site of fetal origin and development. Chronic pelvic pain, exhibited by severe episodes of cyclic pain associated with dysmenorrhea and endometriosis are associated with tender regions and allodynia on the abdominal wall in the vicinity of the acupuncture points. Discomfort perceived on the abdominal surface manifests as a result of viscerosomatic reflexes. Crosstalk between neurons in the spinal cord can lead to viscerovisceral and secondary somatovisceral reflexes that cause symptoms of interstitial cystitis and irritable bower syndrome.[11]

the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as “Fothergill’s sign”.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation.
- **External oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Internal oblique aponeurosis:** Like the external oblique muscle, the internal oblique flexes and rotates the trunk, and supports and compresses the abdominal organs.
- **Transversus abdominis aponeurosis:** In keeping with the oblique muscles, the transversus abdominis muscle compresses and supports the abdominal organs. Like the rectus abdominis muscle, the transversus abdominis muscle acts as an antagonist of the diaphragm to facilitate exhalation.

Nerves

- **Subcostal nerve (T12):** Supplies the skin in this region.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[5] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from the plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively.

Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually cause changes in several spinal cord segments rather than only one level, which works toward the acupuncturist’s advantage by distributing the neuromodulation to a broader territory.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[6] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[7] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[8] Paresis of the abdominal wall may cause large swelling and mechanical complaints.

Vessels

- **Superficial (inferior) epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior (deep) epigastric artery:** Supplies the rectus abdominis muscle and the medial portion of the anterolateral abdominal wall. A branch of the external iliac artery. Anastomoses with the superior epigastric artery within the rectus sheath near the umbilicus.
- **Superficial (inferior) epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior (deep) epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. Collateral venous connections provide alternate routes for venous return from the lower extremities, by bypassing an obstructed or ligated inferior vena cava. Venous blood instead drains into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; around the umbilicus, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep face. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[9] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[10]

Si Man "Fourfold Fullness"

On the lower abdomen, 2 cun inferior to the level of the umbilicus, 0.5 cun lateral to the anterior midline, level with CV 5.

Caution: Deep needling may penetrate the peritoneal cavity.

See Figure 8-32 to examine structures within reach of a deeply placed acupuncture needle. Note as well how the degree of adipose tissue present in the caudal abdomen changes safe needling depth.[1]

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: An epigastric artery rupture or rectus abdominis muscle tear can create a hematoma in the rectus sheath. Once considered rare, rectus sheath hematomata are increasing in frequency and severity.[2] More patients are receiving anti-coagulant medications and the population as a whole is advancing in age. Typically but not exclusively, the patient is an elderly female with acute onset of abdominal pain; examination reveals a palpable mass associated with the history of trauma to the abdomen but not, necessarily, surgery. Missing this diagnosis may lead to unnecessary surgery for a false acute abdomen. In addition, incising the abdominal wall could exacerbate the bleeding by eliminating the natural tamponade the rectus sheath provides, leading to uncontrolled hemorrhage.

The consequences of rectus sheath hematoma range from self-limiting disease to patient demise. Delaying proper treatment could allow a small, initially asymptomatic mass to enlarge and cause signs of abdominopelvic irritation accompanied by mild pyrexia and leukocytosis. Patients experiencing extensive hemorrhage into the rectus sheath exhibit tachycardia, tachypnea, sweating, and related signs of low blood volume.

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[3]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture.[4] About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

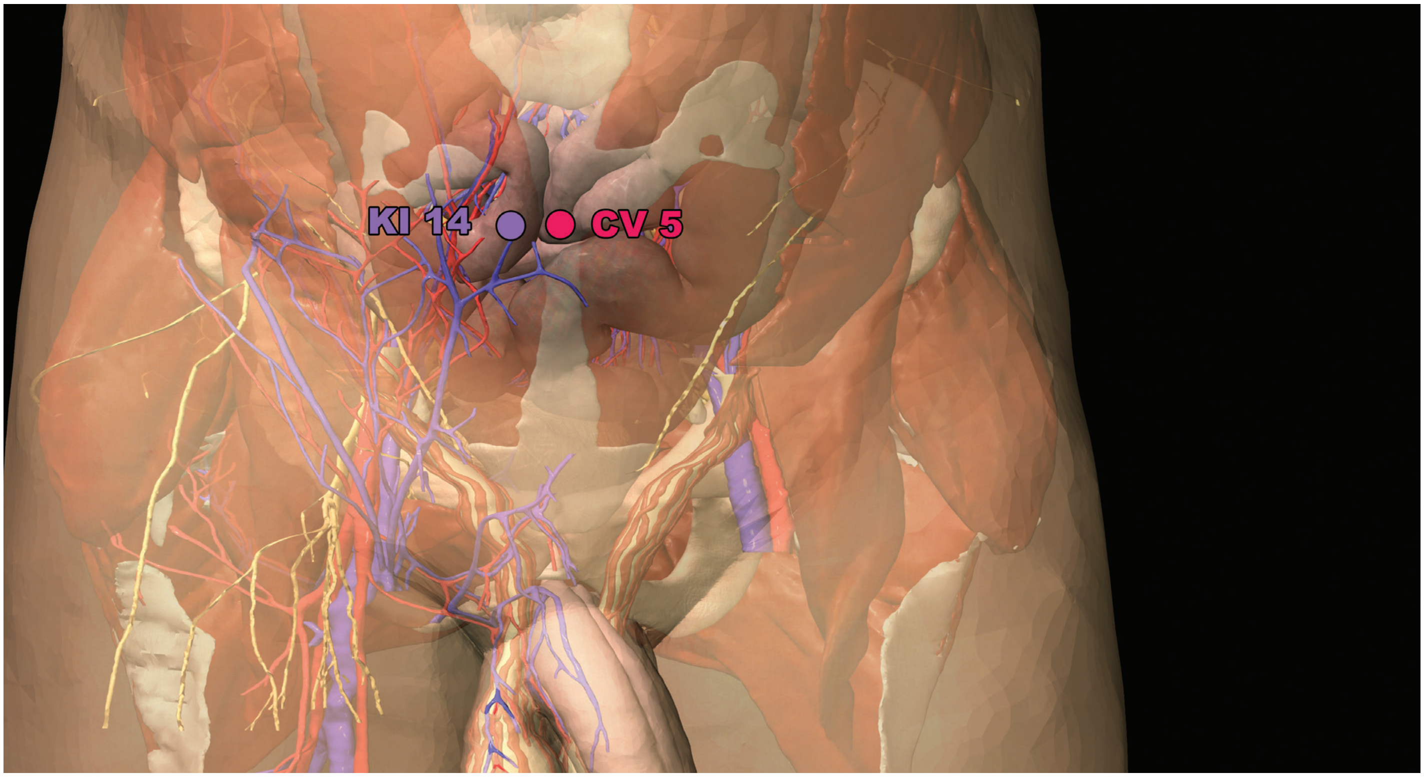

Figure 8-31. Through a window in the abdominal wall at KI 14 and CV 5, the loops of intestines and epigastric vessels become visible by means of layered anatomy. Compare this perspective with that available in the following image, Figure 8-32.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation. The rectus abdominis muscle consists of a cranial and caudal portion demarcated by the arcuate line, landing about 5 cm caudal to the umbilicus, at about the level of KI 14. Transverse tendinous inscriptions or intersections further divide the muscle into segments.

Clinical Relevance: Caudal to the arcuate line of the abdomen, the rectus abdominis loses the protection its deep wall enjoyed cranial to the line. That is, the caudal aspect of the rectus sheath thins in this section of the abdomen as the connective tissue contribution of the obliques and the transversalis muscle dwindles. Thus, only a weak transversalis fascia and peritoneum separate the muscle from the abdominal compartment. This fact raises safety concerns for acupuncturists treating caudal abdominal acupuncture points along the CV, KI, ST, and SP lines, because deep needling carries more risk of entering the abdomen. Compare the cross sections of Figures 8-32 and 8-30. In the former, depicting the placement of KI 14, a tough backing to the rectus sheath better defends the intestines from a penetrating acupuncture needle than it does in Figure 8-30, deep to KI 13. Nevertheless, caution remains warranted, especially when needling the abdomen in thin or anticoagulated patients.

Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress. In the caudal abdomen at KI 14, trigger points can incite a sense of intestinal disturbance.

Nerves

- **Eleventh intercostal nerve:** Supplies the skin in this region.
- **L1 spinal nerve:** Contributes to the nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[5] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from these plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively. Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually cause changes in several spinal cord segments rather than only one level, which works toward the acupuncturist's advantage by distributing the neuromodulation to a broader territory.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[6] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[7] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[8] Paresis of the abdominal wall may cause large swelling and mechanical complaints.

Vessels

- **Superficial (inferior) epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior (deep) epigastric artery**: Supplies the rectus abdominis muscle and the medial portion of the anterolateral abdominal wall. A branch of the external iliac artery. Anastomoses with the superior epigastric artery within the rectus sheath near the umbilicus.
- **Superficial (inferior) epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior (deep) epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. Collateral venous connections provide alternate routes for venous return from the lower extremities, by bypassing an obstructed or ligated inferior vena cava. Venous blood instead drains into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; as they approach the umbilicus as at KI 14, they begin to anastomose with the superior epigastric vessels within the confines of the rectus sheath on its deep face. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A

predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[9] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[10]

Indications and Potential Point Combinations

test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation. The rectus abdominis muscle consists of a cranial and caudal portion demarcated by the arcuate line, landing about 5 cm caudal to the umbilicus, at about the level of KI 14. Transverse tendinous inscriptions or intersections further divide the muscle into segments.

Clinical Relevance: Caudal to the arcuate line of the abdomen, the rectus abdominis loses the protection its deep wall enjoyed cranial to the line. That is, the caudal aspect of the rectus sheath thins in this section of the abdomen as the connective tissue contribution of the obliques and the transversalis muscle dwindles. Thus, only a weak transversalis fascia and peritoneum separate the muscle from the abdominal compartment. This fact raises safety concerns for acupuncturists treating caudal abdominal acupuncture points along the CV, KI, ST, and SP lines, because deep needling carries more risk of entering the abdomen. Compare the cross sections of Figures 8-34 and 8-30. In the former, depicting the placement of KI 15, a tough backing to the rectus sheath better defends the intestines from a penetrating acupuncture needle than it does in Figure 8-30, deep to KI 13. Nevertheless, caution remains warranted, especially when needling the abdomen in thin or anticoagulated patients. Clearly, based on these cross-sections, treatments with laser therapy and massage could readily reach these superficial intestinal segments, addressing inflammation and motility disorders.

Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress. In the caudal abdomen at KI 15, trigger points can incite a sense of intestinal disturbance. The significance of KI 15 as a rectus abdominis trigger point was recognized in the scientific medical literature as far back as 1975.[6]

Nerves

- **11th intercostal nerve:** Supplies the skin in this region.
- **L1 spinal nerve:** Contributes to the nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[7] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from these plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively.

Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually cause changes in several spinal cord segments rather than only one level, which works toward the acupuncturist's advantage by distributing the neuromodulation to a broader territory.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[8] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[9] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[10] Paresis of the abdominal wall may cause large swelling and mechanical complaints.

Vessels

- **Superficial (inferior) epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior (deep) epigastric artery**: Supplies the rectus abdominis muscle and the medial portion of the anterolateral abdominal wall. A branch of the external iliac artery. Anastomoses with the superior epigastric artery within the rectus sheath near the umbilicus.
- **Superficial (inferior) epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior (deep) epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These

valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. Collateral venous connections provide alternate routes for venous return from the lower extremities, by bypassing an obstructed or ligated inferior vena cava. Venous blood instead drains into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.

- **Note about the periumbilical/subumbilical arterial anastomoses:** A rich vascular plexus lies beneath the umbilicus, between the peritoneum and the posterior rectus sheath.[1] This plexus involves a network of vessels arriving via the median umbilical ligament and the ligamentum teres hepaticum – a fibrous, cordlike remnant of the left umbilical vein. Vessels from both sides of the midline participate in the anastomoses. Three sources contribute to the subumbilical vascular plexus: the deep inferior epigastric arteries (via small and large perforating vessels) and the arteries in the ligamentum teres hepaticum and the median umbilical ligament.

- **Note about the periumbilical venous anastomoses:** The superior and inferior epigastric veins anastomose with veins in the falciform ligament to form the periumbilical venous anastomoses. Excessive dilation ("caput medusae") of the periumbilical veins occurs as a consequence of portal hypertension, secondary to liver disease or obstruction.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; as they approach the umbilicus as at KI 15, they anastomose with the superior epigastric vessels within the confines of the rectus sheath on its deep face. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[11] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[12]

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[4]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture.[5] About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's

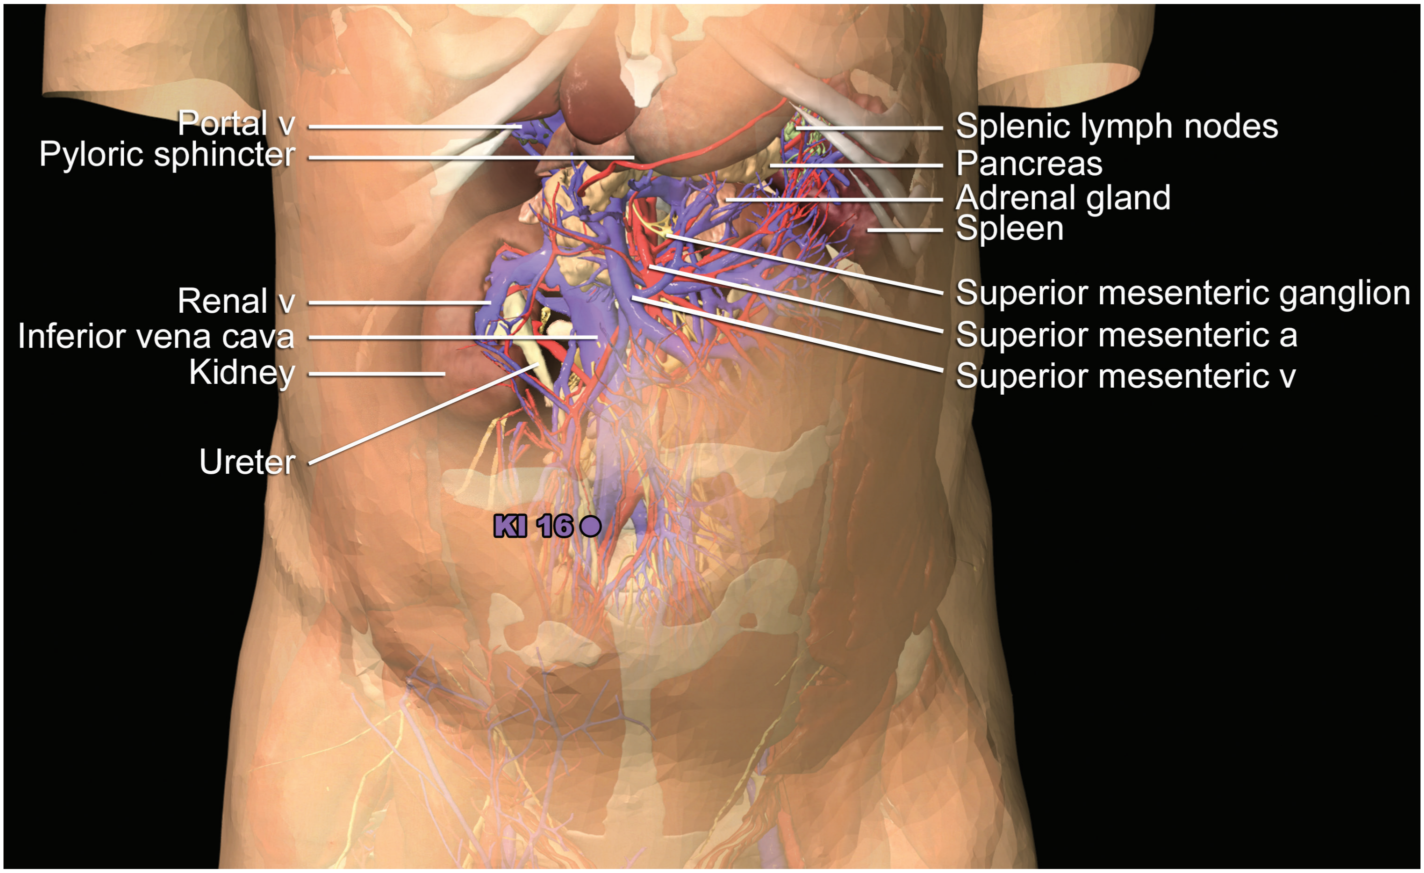

Figure 8-35A. According to Quirico's *Teaching Atlas of Acupuncture*, "From this point (KI 16) the kidney qi spreads to the peritoneum and the abdominal viscera." (P. 116.) This translucent skin image reveals the relationship between the kidneys, the ureter, and the right-hand KI 16. Thus, KI 16 earns its moniker, "Vitals Shu", by ferrying impulses from the body surface to many organs to which it communicates.

test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation. The rectus abdominis muscle consists of a cranial and caudal portion demarcated by the arcuate line, landing about 5 cm caudal to the umbilicus, at about the level of KI 14. Transverse tendinous inscriptions or intersections further divide the muscle into segments.

Clinical Relevance: Caudal to the arcuate line of the abdomen, the rectus abdominis loses the protection its deep wall enjoyed cranial to the line. That is, the caudal aspect of the rectus sheath thins in this section of the abdomen as the connective tissue contribution of the obliques and the transversalis muscle dwindles. Thus, only a weak transversalis fascia and peritoneum separate the muscle from the abdominal compartment. This fact raises safety concerns for acupuncturists treating caudal abdominal acupuncture points along the CV, KI, ST, and SP lines, because deep needling carries more risk of entering the abdomen.

Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress. At the level of the mid-abdomen at KI 16, trigger points can provoke intestinal disturbance, or at least the feeling of impending upset.

Nerves

- **10th intercostal nerve:** Supplies the skin in this region.
- **L1 spinal nerve:** Contributes to the nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[6] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from these plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively.

Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually cause changes in several spinal cord segments rather than only one level, which works toward the acupuncturist's advantage by distributing the neuromodulation to a broader territory.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[7] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[8] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[9] Paresis of the abdominal wall may cause large swelling and mechanical complaints.

Vessels

- **Superficial (inferior) epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior (deep) epigastric artery:** Supplies the rectus abdominis muscle and the medial portion of the anterolateral abdominal wall. A branch of the external iliac artery. Anastomoses with the superior epigastric artery within the rectus sheath near the umbilicus.
- **Superficial (inferior) epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior (deep) epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. Collateral venous connections provide alternate routes for venous return from the lower extremities, by bypassing an obstructed or ligated inferior vena cava. Venous blood instead drains into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.
- **Note about the periumbilical/subumbilical arterial anastomoses:** A rich vascular plexus lies beneath the umbilicus, between the peritoneum and the posterior rectus sheath.[1] This

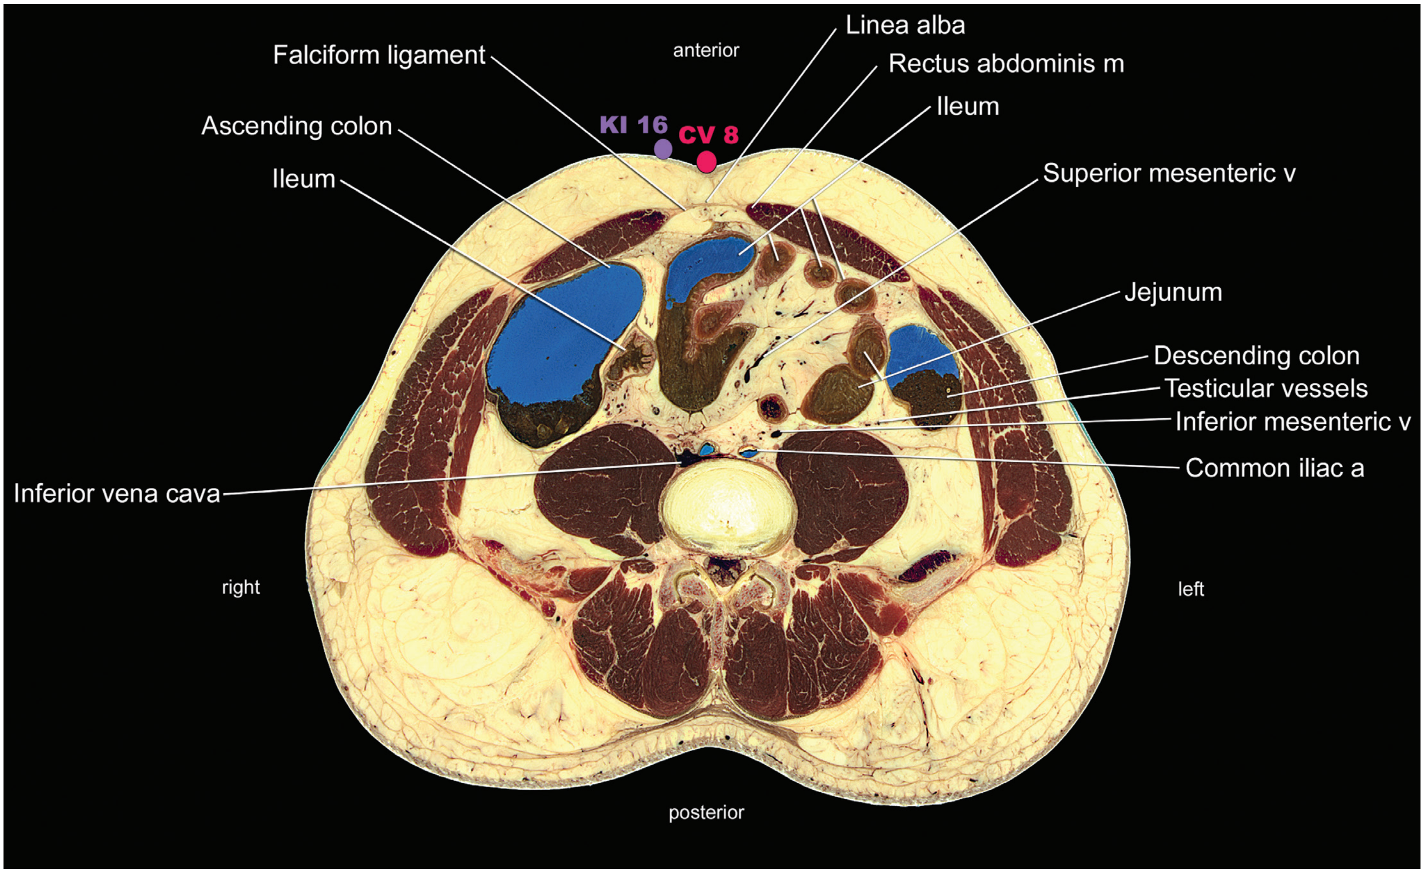

Figure 8-35B. CV 8, within the umbilicus, is considered "forbidden" for needling, whether due to the risk of entering the abdomen or the reverence bestowed on the site by dint of its connection with one's mother. The umbilicus and CV 8 ("Spirit Gate") were claimed to be the door through which the spirit enters and leaves the body and the source of life ("Supreme Unity").[13] With this proscription in mind about avoiding acupuncture at the navel, one can engender similar neuromodulatory benefits by treating territory adjacent to this delicate site, at KI 16.

plexus involves a network of vessels arriving via the median umbilical ligament and the ligamentum teres hepaticum – a fibrous, cordlike remnant of the left umbilical vein. Vessels from both sides of the midline participate in the anastomoses. Three sources contribute to the subumbilical vascular plexus: the deep inferior epigastric arteries (via small and large perforating vessels) and the arteries in the ligamentum teres hepaticum and the median umbilical ligament.

- **Note about the periumbilical venous anastomoses:** The superior and inferior epigastric veins anastomose with veins in the falciform ligament to form the periumbilical venous anastomoses. Excessive dilation ("caput medusae") of the periumbilical veins occurs as a consequence of portal hypertension, secondary to liver disease or obstruction.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; as they reach the periumbilical region KI 16, they anastomose with the superior epigastric vessels within the confines of the rectus sheath on its deep face. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[10] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[11]

Indications and Potential Point Combinations

- **Abdominal pain, cramps, or distension:** KI 16, CV 12, ST 36.
- **Vomiting:** KI 16, PC 6.
- **Diarrhea:** KI 16, SP 6.
- **Constipation, dry stool:** KI 16, SP 6, ST 36, BL 25.
- **Retained placenta:** KI 16, SP 6.[12]

Fascia

- **Rectus sheath:** The strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: An epigastric artery rupture or rectus abdominis muscle tear can create a hematoma in the rectus sheath. Once considered rare, rectus sheath hematomata are increasing in frequency and severity.[2] More patients are receiving anti-coagulant medications and the population as a whole is advancing in age. Typically but not exclusively, the patient is an elderly female with acute onset of abdominal pain; examination reveals a palpable mass associated with the history of trauma to the abdomen but not, necessarily, surgery. Missing this diagnosis may lead to unnecessary surgery for a false acute abdomen. In addition, incising the abdominal wall could exacerbate the bleeding by eliminating the natural tamponade the rectus sheath provides, leading to uncontrolled hemorrhage.

The consequences of rectus sheath hematoma range from self-limiting disease to patient demise. Delaying proper treatment could allow a small, initially asymptomatic mass to enlarge and cause signs of abdominopelvic irritation accompanied by mild pyrexia and leukocytosis. Patients experiencing extensive hemorrhage into the rectus sheath exhibit tachycardia, tachypnea, sweating, and related signs of low blood volume.

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[3]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture.[4] About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

Falciform Ligament

- This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal

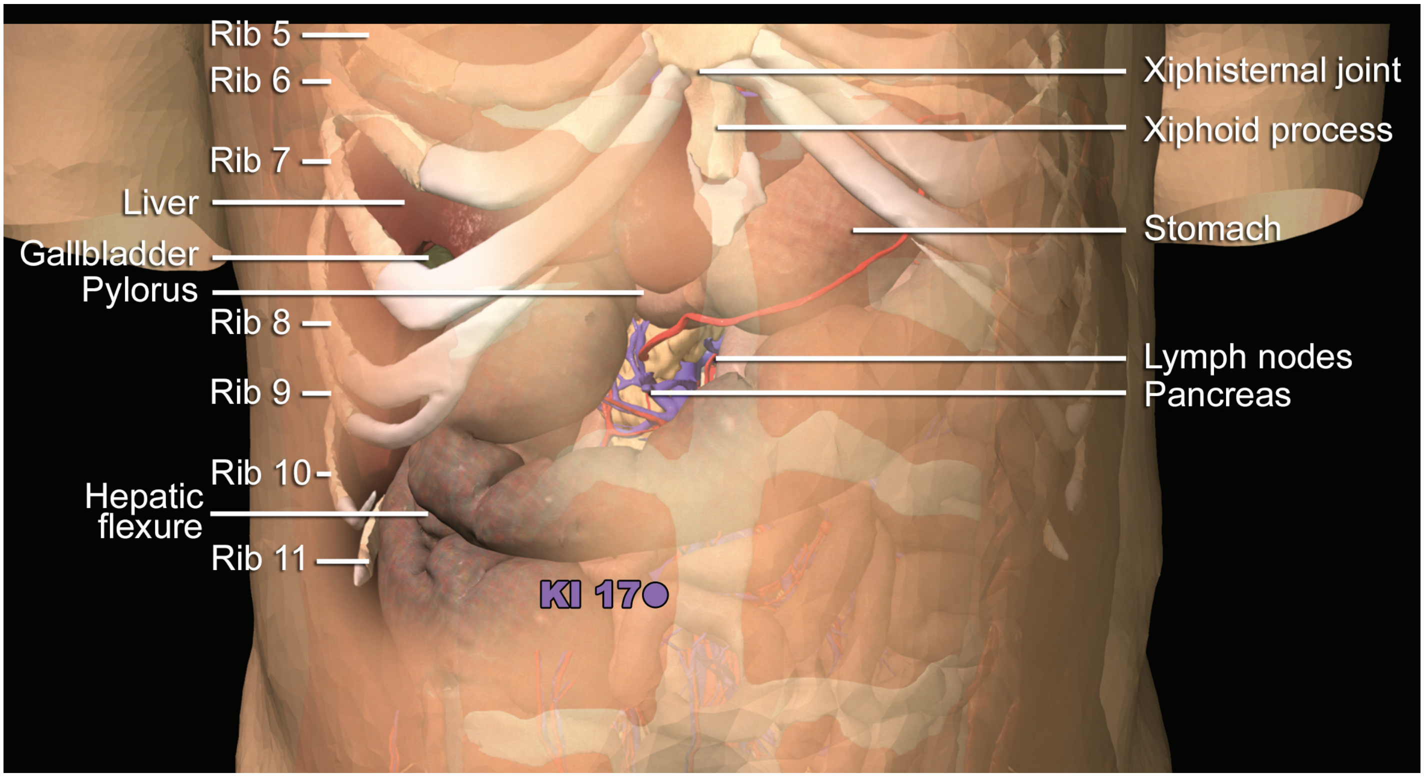

Figure 8-36. KI 17, "Shang Bend", refers to the sharp bend in the colon at the right colic, or hepatic, flexure, shown here through a window in the abdominal wall.

portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. This explains the appearance of the ligament at KI 17 but not KI 16 caudal. It comprises two mesothelial layers of peritoneum filled with extra-peritoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[5] Venous blood from the falciform drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

Clinical Relevance: Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[6] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[7] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[8] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[9] Sepsis involving the ligament can arise from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is showing increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI 17 and other locations in the region may offer adjunctive support but should delay appropriate diagnosis and surgical treatment if warranted. Furthermore, acupuncture at the KI and CV points between the sternum and umbilicus should not enter the abdomen nor invade the falciform ligament. Rather, the effect of needling might be able to indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation.

The rectus abdominis muscle consists of a cranial and caudal portion demarcated by the arcuate line, landing about 5 cm caudal to the umbilicus, at about the level of KI 14. Transverse tendinous inscriptions or intersections further divide the muscle into segments.

Clinical Relevance: Caudal to the arcuate line of the abdomen, the rectus abdominis loses the protection its deep wall enjoyed cranial to the line. That is, the caudal aspect of the rectus sheath thins in this section of the abdomen as the connective tissue contribution of the obliques and the transversalis muscle dwindles. Thus, only a weak transversalis fascia and peritoneum separate the muscle from the abdominal compartment. This fact raises safety concerns for acupuncturists treating caudal abdominal acupuncture points along the CV, KI, ST, and SP lines, because deep needling carries more risk of entering the abdomen.

Trigger points in the more cranial rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral reflexes leading to feelings of abdominal fullness, nausea, and vomiting. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress.

Rectus abdominis trigger points may secondarily arise as a result of internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. At the level of the mid-abdomen at KI 17, trigger points can signal or provoke intestinal disturbance, or at least raise the worry of impending upset.

Nerves

- **9th intercostal nerve:** Supplies the skin in this region.
- **L1 spinal nerve:** Contributes to the nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[10] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from these plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively.

Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually cause changes in several spinal cord segments

rather than only one level, which works toward the acupuncturist's advantage by distributing the neuromodulation to a broader territory.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[11] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[12] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[13] Paresis of the abdominal wall may cause large swelling and mechanical complaints.

Vessels

- **Superior superficial epigastric artery:** Supplies the subcutaneous tissue and skin above the umbilicus. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior superficial epigastric artery.
- **Superior deep epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superior superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial inferior epigastric vein is a tributary of the great saphenous vein while the superior epigastric vein carries deoxygenated blood and drains into the internal thoracic vein. The superior and inferior superficial epigastric vessels anastomose at the level of the umbilicus.
- **Superior deep epigastric vein:** The superior epigastric vein, like its superficial counterpart, empties into the internal thoracic vein. Valves in the superior deep epigastric veins direct blood flow craniad, while those in the inferior group send blood caudad.[14]
- **Note about the periumbilical arterial anastomoses:** A rich vascular plexus lies beneath the umbilicus, between the peritoneum and the posterior rectus sheath.[1] This plexus incorporates a network of vessels arriving via the median umbilical ligament and the ligamentum teres hepaticum, a fibrous, cordlike remnant of the left umbilical vein. Vessels from both sides of the midline communicate with the anastomoses. Three sources contribute to the subumbilical vascular plexus: the deep inferior

epigastric arteries (via small and large perforating vessels) and the arteries in the ligamentum teres hepaticum and the median umbilical ligament.

- **Note about the periumbilical venous anastomoses:** The superior and inferior epigastric veins anastomose with veins in the falciform ligament to form the periumbilical venous anastomoses. Excessive dilation ("caput medusae") of the periumbilical veins occurs as a consequence of portal hypertension, secondary to liver disease or obstruction.

Clinical Relevance: The anatomical layout of vessels around the umbilicus becomes of heightened importance during body contouring procedures such as abdominoplasty.[15] The venous drainage of the abdominal wall is even more variable than the arterial network, accentuating the risk of insufficient circulatory recovery of blood supply and drainage after abdominoplasty and transverse rectus abdominis myocutaneous (TRAM) flap reconstructions.

Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues.

Indications and Potential Point Combinations

- **Constipation:** KI 17, ST 25, ST 36.
- **Insomnia:** KI 17, KI 16, ST 24, ST 26, CV 4, CV 6, CV, 10, and CV 12.

Evidence-Based Application

- Acupuncture at KI 17, ST 24, Xiafengshidian, Qipang, CV 4, CV 6, CV 10, CV 12 aided in alleviating **insomnia** in women and was significantly more effective than a benzodiazepine, estazolam.[16] Qipang is located near the umbilicus, just lateral to KI 15. Xiafengshidian is found lateral and caudal to ST 26.

became more prominent; a feature known as “Fothergill’s sign”.

Falciform Ligament

- This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. This explains the appearance of the ligament at KI 17-KI 21 but not at KI 16 and those more caudal. It comprises two mesothelial layers of peritoneum filled with extra-peritoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[4] Venous blood from the falciform drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

Clinical Relevance: Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[5] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[6] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[7] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[8] Sepsis involving the ligament can arise from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is showing increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI 18 and other locations in the region may offer adjunctive support but should delay appropriate diagnosis and surgical treatment if warranted. Furthermore, acupuncture at the KI and CV points between the sternum and umbilicus should not enter the abdomen nor invade the falciform ligament. Rather, the effect of needling might be able to indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation. The rectus abdominis muscle consists of a cranial and caudal portion demarcated by the arcuate line, landing about 5 cm caudal to the umbilicus, at about the level of KI 14. Transverse tendinous inscriptions or intersections further divide the muscle into segments.

Clinical Relevance: Caudal to the arcuate line of the abdomen, the rectus abdominis loses the protection its deep wall enjoyed cranial to the line. That is, the caudal aspect of the rectus sheath thins in this section of the abdomen as the connective tissue contribution of the obliques and the transversalis muscle dwindles. Thus, only a weak transversalis fascia and peritoneum separate the muscle from the abdominal compartment. This fact raises safety concerns for acupuncturists treating caudal abdominal acupuncture points along the CV, KI, ST, and SP lines, because deep needling carries more risk of entering the abdomen.

Trigger points in the more cranial rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral reflexes leading to feelings of abdominal fullness, nausea, and vomiting. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as “heartburn” and epigastric distress.

Rectus abdominis trigger points may secondarily arise as a result of internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. At the level of the mid-abdomen at KI 18, trigger points can signal or provoke intestinal disturbance, or at least raise the worry of impending upset.

Nerves

- **8th intercostal nerve:** Supplies the skin in this region.
- **L1 spinal nerve:** Contributes to the nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[9] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from these plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively.

Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade

as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually cause changes in several spinal cord segments rather than only one level, which works toward the acupuncturist's advantage by distributing the neuromodulation to a broader territory.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[10] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[11] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[12] Paresis of the abdominal wall may cause large swelling and mechanical complaints.

Vessels

- **Superior superficial epigastric artery:** Supplies the subcutaneous tissue and skin above the umbilicus. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior superficial epigastric artery.
- **Superior deep epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superior superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial inferior epigastric vein is a tributary of the great saphenous vein while the superior epigastric vein drains deoxygenated blood into the internal thoracic vein. The superior and inferior superficial epigastric vessels anastomose at the level of the umbilicus.
- **Superior deep epigastric vein:** The superior epigastric vein, like its superficial counterpart, empties into the internal thoracic vein. Valves in the superior deep epigastric veins direct blood flow craniad, while those in the inferior group send blood caudad.[13]

Clinical Relevance: The anatomical layout of vessels around the umbilicus becomes of heightened importance during body contouring procedures such as abdominoplasty.[14] The venous drainage of the abdominal wall is even more variable than the arterial network, accentuating the risk of insufficient circulatory recovery of blood supply and drainage after abdominoplasty and transverse rectus abdominis myocutaneous (TRAM) flap reconstructions.

Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues.

Caution: Deep needling may penetrate the peritoneal cavity.

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: An epigastric artery rupture or rectus abdominis muscle tear can create a hematoma in the rectus sheath. Once considered rare, rectus sheath hematomata are increasing in frequency and severity.[1] More patients are receiving anti-coagulant medications and the population as a whole is advancing in age. Typically but not exclusively, the patient is an elderly female with acute onset of abdominal pain; examination reveals a palpable mass associated with the history of trauma to the abdomen but not, necessarily, surgery. Missing this diagnosis may lead to unnecessary surgery for a false acute abdomen. In addition, incising the abdominal wall could exacerbate the bleeding by eliminating the natural tamponade the rectus sheath provides, leading to uncontrolled hemorrhage.

The consequences of rectus sheath hematoma range from self-limiting disease to patient demise. Delaying proper treatment could allow a small, initially asymptomatic mass to enlarge and cause signs of abdominopelvic irritation accompanied by mild pyrexia and leukocytosis. Patients experiencing extensive hemorrhage into the rectus sheath exhibit tachycardia, tachypnea, sweating, and related signs of low blood volume.

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[2]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture. About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

Falciform Ligament

- This sickle-shaped ligament attaches the liver to the ventral

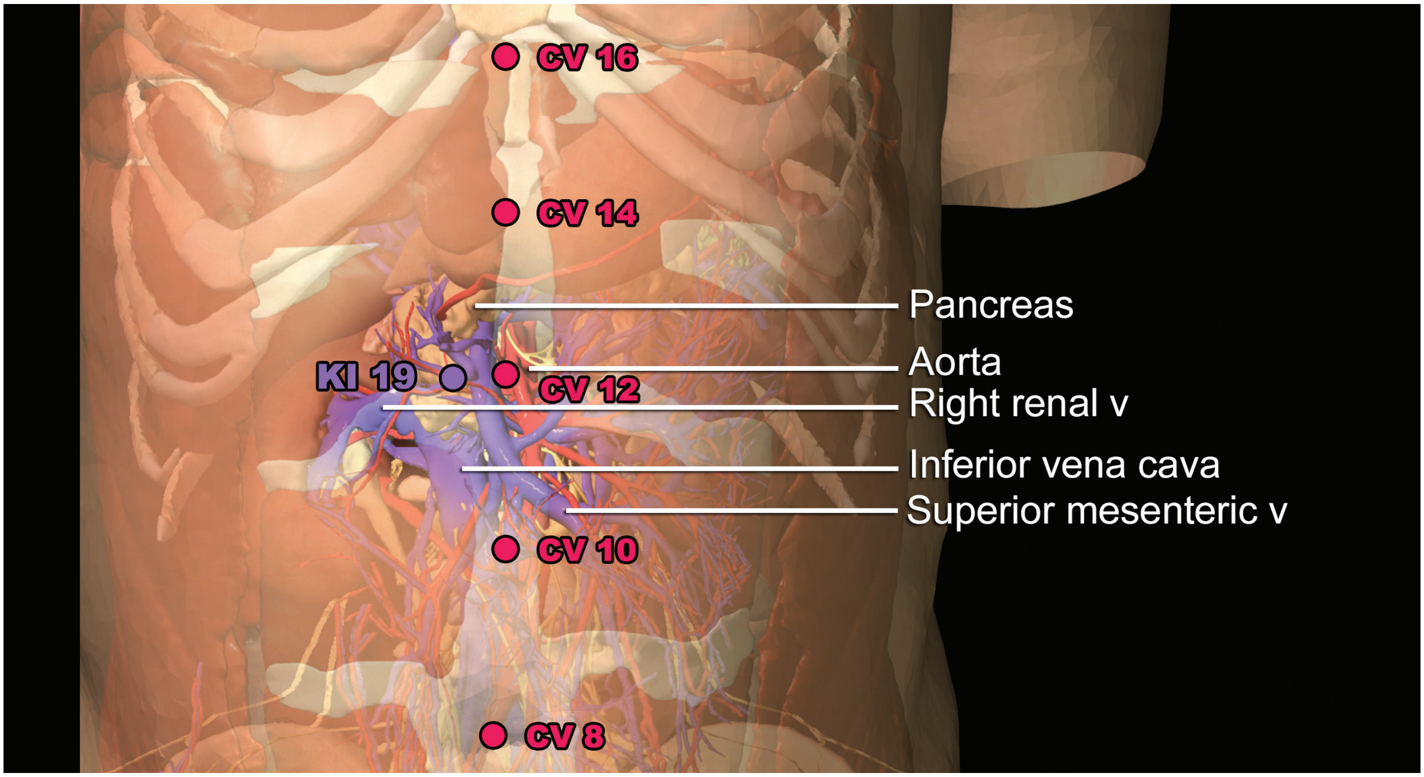

Figure 8-40. KI 19, the "Yin Metropolis", hovers over a complex array of vessels, usually covered by organs. "Yin" refers to the blood moved throughout these arteries and veins, coming and going as though along expressways interlacing betwixt and between buildings in a busy city, or metropolis.

body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. This explains the appearance of the ligament at KI 17-KI 21 but not at KI 16 and those more caudal. It comprises two mesothelial layers of peritoneum filled with extraperitoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[4] Venous blood from the falciform drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

Clinical Relevance: Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[5] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[6] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[7] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[8] Sepsis involving the ligament can arise from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is showing increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI 19 and other locations in the region may offer adjunctive support but should delay appropriate diagnosis and surgical treatment if warranted. Furthermore, acupuncture at the KI and CV points between the sternum and umbilicus should not enter the abdomen nor invade the falciform ligament. Rather, the effect of needling might be able to indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature.

Nerves

- **7th intercostal nerve:** Supplies the skin in this region.
- **L1 spinal nerve:** Contributes to the nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[9] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Vessels

- **Superior epigastric artery:** Supplies the subcutaneous tissue and skin in the hypogastrium. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior epigastric artery.
- **Superior epigastric vein:** The superior epigastric veins are tributaries of the internal thoracic veins. They anastomose with the inferior epigastric veins inside the rectus sheath. These valveless veins can act as collateral routes for abdominopelvic blood return to the heart and provide a route for venous return from the lower extremities when needed. They allow venous blood to bypass the inferior vena cava in cases of obstruction or ligation and instead to drain into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.

Clinical Relevance: Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[10] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[11]

Figure 8-41. This cross-section at the level of "Yin Metropolis", or KI 19, brings together organs and vessels like a city packed with office buildings and roadways, managing the day to day "business" of bodily functions.

Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic as in severe aortoiliac occlusive disease, these superficial vessels on the abdominal wall provide collateral pathways for circulation. These communicating vessels course within loose areolar tissue deep to the rectus abdominis muscle. They constitute a lengthy anastomosis between the femoral vessels of the pelvis and the internal thoracic (internal mammary) vessels of the chest.

Acupuncture should be avoided in an area of abdominal wall expansion if rectus hematoma is suspected. However, after appropriate measures have controlled the bleeding and hypotensive consequences, neuromodulation may be attempted with non-invasive means to improve recovery of the area. That is, while acupuncture, laser therapy, and massage would be contraindicated in the acute phase where bleeding is active, they may be appropriate after the risk of hemorrhage has passed and if employed cautiously and judiciously to avoid and prevent further vessels damage.

Indications and Potential Point Combinations

- **Abdominal distension, feeling of fullness in the chest:** KI 19, KI 22, CV 17, ST 36.

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: An epigastric artery rupture or rectus abdominis muscle tear can create a hematoma in the rectus sheath. Once considered rare, rectus sheath hematomata are increasing in frequency and severity.[1] More patients are receiving anti-coagulant medications and the population as a whole is advancing in age. Typically but not exclusively, the patient is an elderly female with acute onset of abdominal pain; examination reveals a palpable mass associated with the history of trauma to the abdomen but not, necessarily, surgery. Missing this diagnosis may lead to unnecessary surgery for a false acute abdomen. In addition, incising the abdominal wall could exacerbate the bleeding by eliminating the natural tamponade the rectus sheath provides, leading to uncontrolled hemorrhage.

The consequences of rectus sheath hematoma range from self-limiting disease to patient demise. Delaying proper treatment could allow a small, initially asymptomatic mass to enlarge and cause signs of abdominopelvic irritation accompanied by mild pyrexia and leukocytosis. Patients experiencing extensive hemorrhage into the rectus sheath exhibit tachycardia, tachypnea, sweating, and related signs of low blood volume.

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[2]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture.[3] About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

Falciform Ligament

- This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as

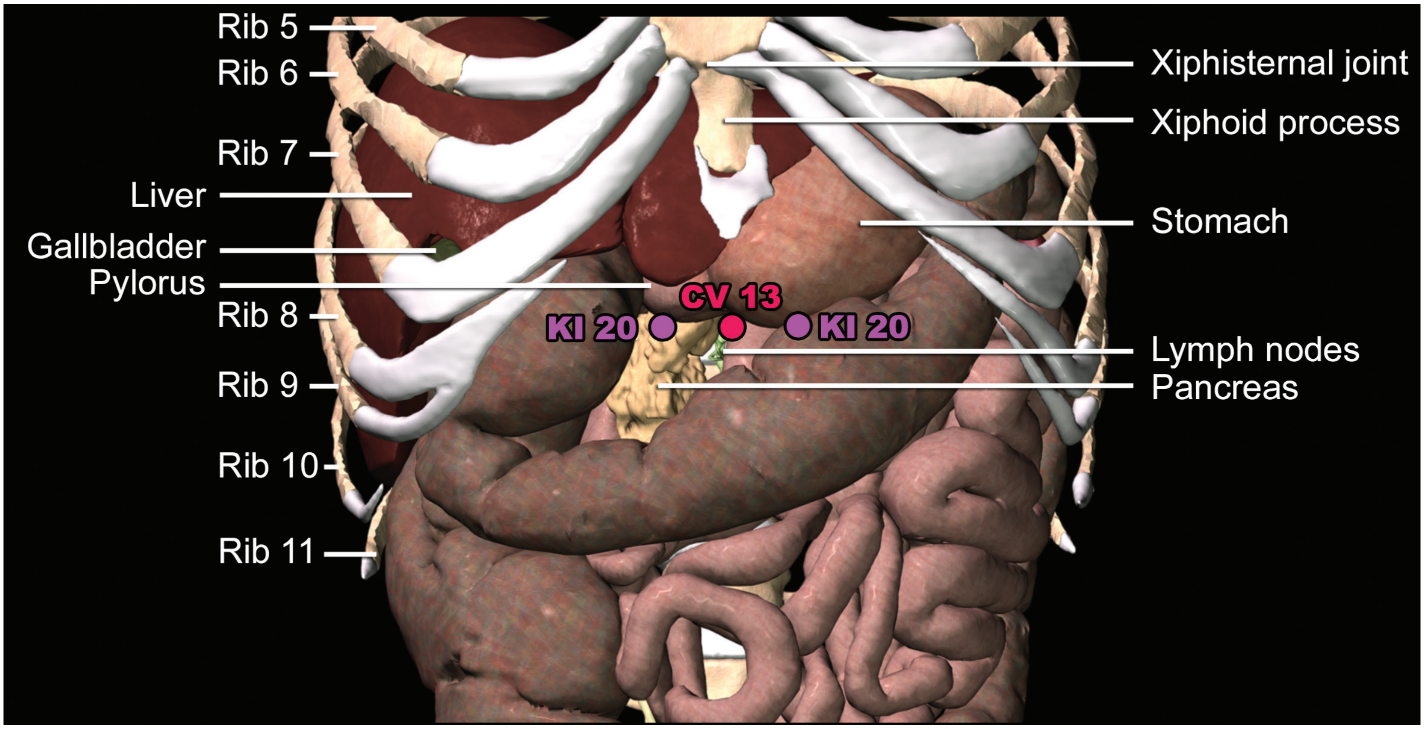

Figure 8-42. This image shows how the organs beneath KI 20 create an "Open Valley" beneath the point..

far down as the umbilicus. This explains the appearance of the ligament at KI 17-KI 21 but not at KI 16 and those more caudal. It comprises two mesothelial layers of peritoneum filled with extra-peritoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[4] Venous blood from the falciform drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

Clinical Relevance: Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[5] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[6] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[7] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[8] Sepsis involving the ligament can arise from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is showing increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI 20 and other locations in the region may offer adjunctive support but should delay appropriate diagnosis and surgical treatment if warranted. Furthermore, acupuncture at the KI and CV points between the sternum and umbilicus should not enter the abdomen nor invade the falciform ligament. Rather, the effect of needling might be able to indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature.

Nerves

- **7th intercostal nerve:** Supplies the skin in this region.
- **L1 spinal nerve:** Contributes to the nerve supply of the internal oblique and transverse abdominal muscles and their aponeuroses.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[9] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the hypogastrium. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle.

It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior epigastric artery.

- **Superior epigastric vein:** The superior epigastric veins are tributaries of the internal thoracic veins. They anastomose with the inferior epigastric veins inside the rectus sheath. These valveless veins can act as collateral routes for abdominopelvic blood return to the heart and provide a route for venous return from the lower extremities when needed. They allow venous blood to bypass the inferior vena cava in cases of obstruction or ligation and instead to drain into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.

Clinical Relevance: Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[10] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[11]

Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic as in severe aortoiliac occlusive disease, these superficial vessels on the abdominal

wall provide collateral pathways for circulation. These communicating vessels course within loose areolar tissue deep to the rectus abdominis muscle. They constitute a lengthy anastomosis between the femoral vessels of the pelvis and the internal thoracic (internal mammary) vessels of the chest.

Acupuncture should be avoided in an area of abdominal wall expansion if rectus hematoma is suspected. However, after appropriate measures have controlled the bleeding and hypotensive consequences, neuromodulation may be attempted with non-invasive means to improve recovery of the area. That is, while acupuncture, laser therapy, and massage would be contraindicated in the acute phase where bleeding is active, they may be appropriate after the risk of hemorrhage has passed and if employed cautiously and judiciously to avoid and prevent further vessels damage.

KI 21

You Men "Hidden Gate", "Dark Gate"

On the epigastrium, 1 cun inferior to the xiphoid process, 6 cun superior to the umbilicus, 0.5 cun lateral to the midline, at approximately the 6th intercostal space.

(May overlie the pylorus. Also, deep needling may puncture the liver on the right and the peritoneum on the left.)

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: An epigastric artery rupture or rectus abdominis muscle tear can create a hematoma in the rectus sheath. Once considered rare, rectus sheath hematomata are increasing in frequency and severity.[1] More patients are receiving anti-coagulant medications and the population as a whole is advancing in age. Typically but not exclusively, the patient is an elderly female with acute onset of abdominal pain; examination reveals a palpable mass associated with the history of trauma to the abdomen but not, necessarily, surgery. Missing this diagnosis may lead to unnecessary surgery for a false acute abdomen. In addition, incising the abdominal wall could exacerbate the bleeding by eliminating the natural tamponade the rectus sheath provides, leading to uncontrolled hemorrhage.

The consequences of rectus sheath hematoma range from self-limiting disease to patient demise. Delaying proper treatment could allow a small, initially asymptomatic mass to enlarge and cause signs of abdominopelvic irritation accompanied by mild pyrexia and leukocytosis. Patients experiencing extensive hemorrhage into the rectus sheath exhibit tachycardia, tachypnea, sweating, and related signs of low blood volume.

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[2]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture.[3] About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

Falciform Ligament

- This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. This explains the appearance of the ligament at KI 17-KI 21 but not at KI 16 and those more caudal. It comprises two mesothelial layers of peritoneum filled with extra-peritoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in

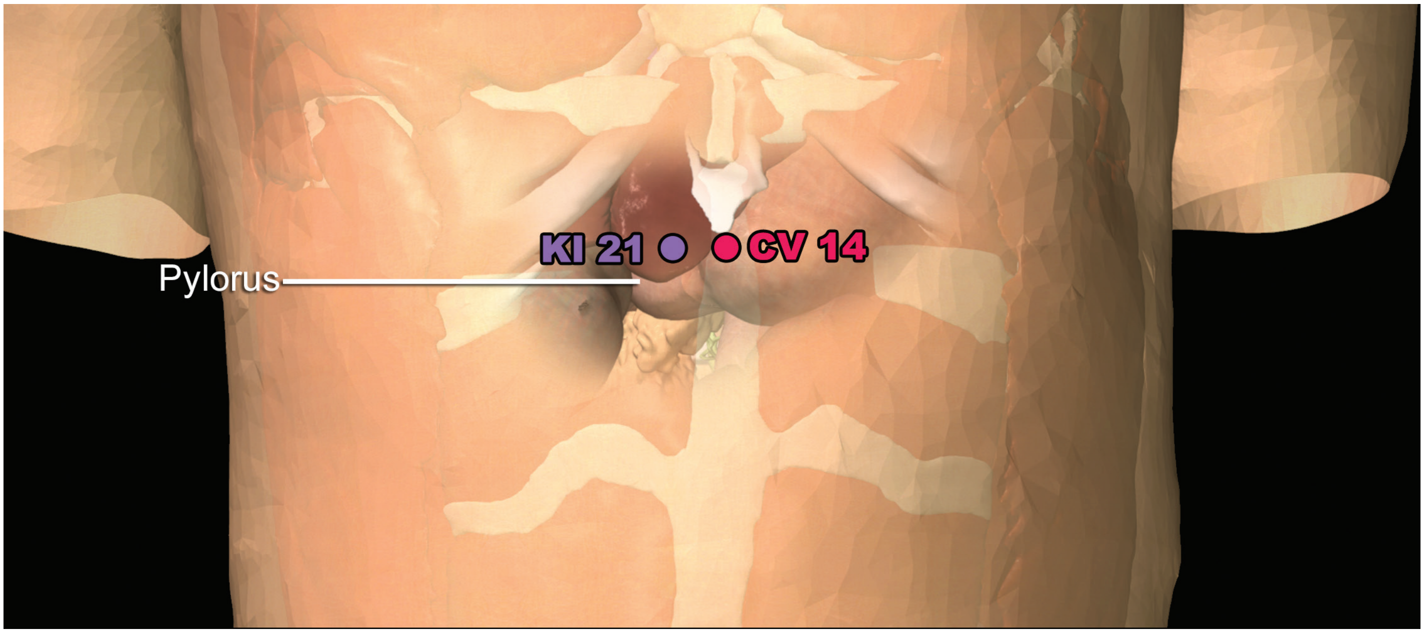

Figure 8-44. The descriptive titile for KI 21, "Hidden (or Dark) Gate" refers to the pylorus and its sphincter, revealed here deep to the point.

patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[4] Venous blood from the falciform drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

Clinical Relevance: Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[5] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[6] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[7] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[8] Sepsis involving the ligament can arise from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is showing increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI 21 and other locations in the region may offer adjunctive support but should delay appropriate diagnosis and surgical treatment if warranted. Furthermore, acupuncture at the KI and CV points between the sternum and umbilicus should not enter the abdomen nor invade the falciform ligament. Rather, the effect of needling might be able to indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature.

Nerves

- **6th intercostal nerve:** Supplies the skin in this region.
- **L1 spinal nerve:** Contributes to the nerve supply of the internal oblique and transverse abdominal muscles and their aponeuroses.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[9] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Vessels

- **Superior epigastric artery:** A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior epigastric artery.
- **Superior epigastric vein:** The superior epigastric veins are tributaries of the internal thoracic veins. They anastomose with the inferior epigastric veins inside the rectus sheath. These valveless veins can act as collateral routes for abdominopelvic blood return to the heart and provide a route for venous return from the lower extremities when needed. They allow venous blood to bypass the inferior vena cava in cases of obstruction or ligation and instead to drain into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.
- **6th intercostal artery:** Supplies the intercostal muscles, overlying skin, and parietal pleura.
- **6th intercostal vein:** Drains the intercostal muscles, overlying skin, and parietal pleura.

Clinical Relevance: Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic, these superficial vessels on the abdominal wall provide collateral pathways for circulation.

Indications and Potential Point Combinations

KI 22

Bu Lang "Walking Corridor"

On the chest, in the 5th intercostal space, 2 cun lateral to the midline, level with CV 16, adjacent to the sternum.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle:** A powerful adductor of the arm. Rotates the humerus in a medial direction. KI 22 overlaps with the location of the "cardiac arrhythmia" trigger point.[2] Note the proximity of the heart (seen with yellow denoting pericardial fat) to KI 22 in Figure 8-46.
- **Sternalis muscle:** An inconstant, strap-like muscle that may be unilateral, bilateral, or absent. It joins the rectus abdominis to the sternal head of the sternocleidomastoid muscle. Lies superficially and perpendicular to the pectoralis major muscle;[3] parallels the KI channel on either side of the sternum. Historically, the sternalis was considered a variant of the pectoralis major or rectus abdominis muscle. Its innervation varies as well.

Clinical Relevance: Sternalis trigger points develop anywhere along its course. Symptoms of sternalis trigger points include deep, intense, substernal pain; the sternum itself may become sore. As such, myofascial dysfunction in the sternalis at the level of KI 22 could mimic cardiogenic pain. Components of the referred pain pattern may extend to the ipsilateral PC or HT channel to PC 3 or HT 3.

Nerves

- **5th intercostal nerve:** Supplies the skin and muscles in this region.
- **Medial pectoral nerve (C7, C8, T1):** Supplies the caudal portion of the pectoralis major as well as the pectoralis minor muscle. May also innervate the sternalis muscle when present.
- **Lateral pectoral nerve (C5-C7):** Supplies the clavicular and sternal portions of the pectoralis major muscle; may also innervate the sternalis muscle when present.

Clinical Relevance: The pectoral nerves exhibit wide variability in their course, origin communications with other nerves, and presence or absence of sensory fibers.[4] They are susceptible to injury from direct trauma, compression from hypertrophied musculature, and iatrogenic injury during mastectomy and breast augmentation. Chronic pain affects up to half of patients undergoing augmentation mammoplasty. The pain centers on the breasts or refers to other regions, including the sternum, infraclavicular tissue, lateral chest wall to the axilla, or interscapular territory on the back.[5] Sternal pain likely results from traction on the lateral pectoral nerve during surgery, given that the nerve supplies both the clavicular and sternal portions of the pectoralis major muscle. Before pursuing invasive methods to treat neuralgia affecting the intercostal or pectoral nerves, acupuncture, manual therapy, and laser therapy (for nonmalignant conditions) should be considered. Caution is warranted, however, with needling near breast implants.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) has the potential to produce chronic pain syndromes: postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[6] The latter condition arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves. The neuromas typically appear on the left intercostal spaces and develop following insertion of sternal wires or needles located at the sternal margin of the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

A wide array of somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27. These problems include costochondritis, physical trauma, upper thoracic somatic dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Mechanisms involve somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal

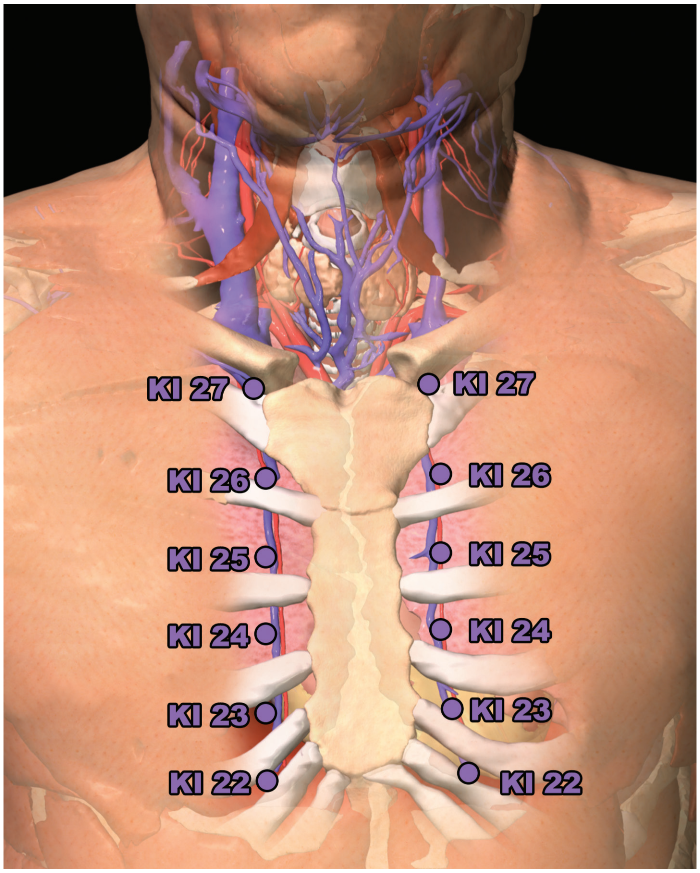

Figure 8-46. The corridor alluded to as "Walking Corridor" follows each side of the sternum in conjunction with the internal thoracic vessels, progressing step by step within each intercostal space. Note the relationship of the heart deep to KI 22 and KI 23, denoted in yellow by pericardial fat.

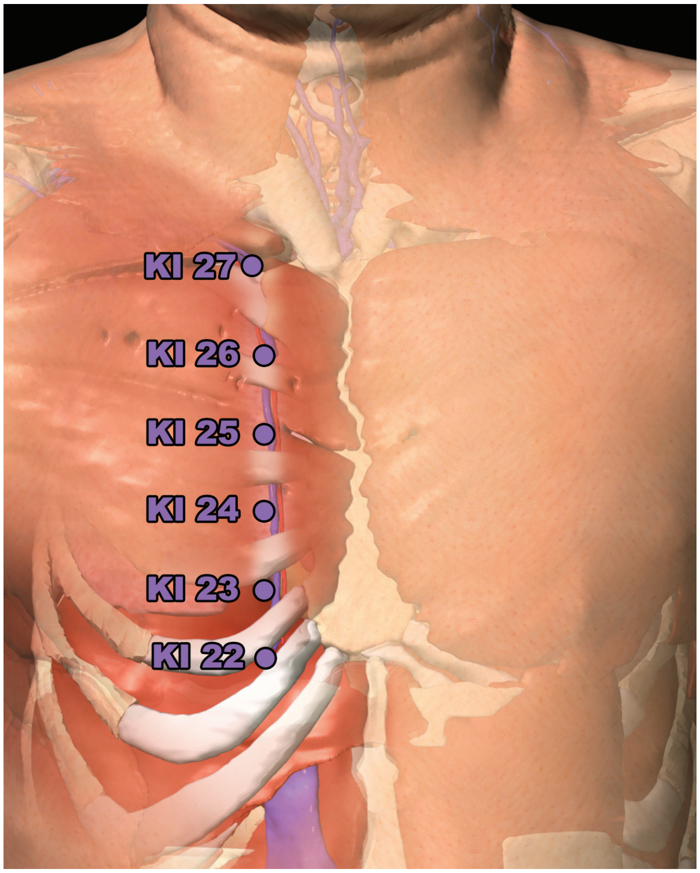

Figure 8-47. KI 22 overlies the diaphragm, thereby explaining its value for problems related to respiration insofar as moving air.

nerves themselves. Neuromodulation addresses peripheral nerve "unhappiness" as well as upper thoracic spinal cord changes resulting from nociceptive afferent bombardment originating in dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

- **Internal thoracic (formerly, internal mammary) artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[7]
- **Internal thoracic (formerly, internal mammary) vein:** The internal thoracic veins accompany the internal thoracic arteries. The anterior intercostal veins are tributaries of the internal thoracic veins.
- **5th intercostal artery:** Supplies the intercostal muscles, overlying skin, and parietal pleura.
- **5th intercostal vein:** Drains the intercostal muscles, overlying skin, and parietal pleura.

Clinical Relevance: The internal thoracic vessels (formerly known as the internal mammary vessels) represent a continuation from the superior epigastric vessels that also parallel the KI channel. At each intercostal space demarcated by KI 22 to KI 26, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[8]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Respiratory problems:** asthma, dyspnea, pleuritis, tracheitis, bronchitis: KI 22, LU 1, LU 2, BL 13.
- **Local pain, intercostal neuralgia:** KI 22, local trigger points.
- **Feeling of chest constriction, radiation of pain to the ulnar aspect of the arm to the ring and little fingers, mimicking pain of angina pectoris:** KI 22; check for trigger points in the pectoralis major attachment to the sternalis, in the location of KI 22.

Other structures of interest include the transversus thoracis muscle, diaphragm, and liver, all of which may be impacted by laser therapy, massage, and (albeit indirectly) acupuncture.

KI 23

Shen Feng "Spirit Border", "Spirit Seal"

On the chest, in the 4th intercostal space, 2 cun lateral to the midline, level with CV 17.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle:** A powerful adductor of the arm. Rotates the humerus mediad.
- **Sternalis muscle:** An inconstant, strap-like muscle that may be unilateral, bilateral, or absent. It joins the rectus abdominis to the sternal head of the sternocleidomastoid muscle. Lies superficial to and fibers run perpendicular to the pectoralis major muscle;[2] parallels the KI channel on either side of the sternum. Historically, the sternalis was considered a variant of the pectoralis major or rectus abdominis muscle. Its innervation varies.

Clinical Relevance: Sternalis trigger points develop anywhere along its course. Symptoms of sternalis trigger points include deep, intense, substernal pain; the sternum itself may become sore. As such, myofascial dysfunction in the sternalis in the region of KI 23 could mimic cardiogenic pain. Components of the referred pain pattern may extend to the ipsilateral PC or HT channel to PC 3 or HT 3.

Nerves

- **4th intercostal nerve:** Supplies the skin and muscles in this region.
- **Medial pectoral nerve (C7, C8, T1):** Supplies the caudal portion of the pectoralis major as well as the pectoralis minor muscle. May also innervate the sternalis muscle when present.
- **Lateral pectoral nerve (C5-C7):** Supplies the cranial part of the pectoralis major muscle; may also innervate the sternalis muscle when present.

Clinical Relevance: The pectoral nerves exhibit wide variability in their course, origin communications with other nerves, and presence or absence of sensory fibers.[3] They are susceptible to injury from direct trauma, compression from hypertrophied musculature, and iatrogenic injury during mastectomy and breast augmentation. Chronic pain affects up to half of patients undergoing augmentation mammoplasty. The pain centers on the breasts or refers to other regions, including the sternum, infraclavicular tissue, lateral chest wall to the axilla, or interscapular territory on the back.[4] Sternal pain likely results from traction on the lateral pectoral nerve during surgery, given that the nerve supplies both the clavicular and sternal portions of the pectoralis major muscle. Before pursuing invasive methods to treat neuralgia affecting the intercostal or pectoral nerves, acupuncture, manual therapy, and laser therapy (for nonmalignant conditions) should be considered. Caution is warranted, however, with needling near breast implants.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) has the potential to produce chronic pain syndromes: postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[5] The latter condition arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves. The neuromas typically appear on the left intercostal spaces and develop following insertion of sternal wires or

needles located at the sternal margin of the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

A wide array of somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27. These problems include costochondritis, physical trauma, upper thoracic somatic dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Mechanisms involve somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve "unhappiness" as well as upper thoracic spinal cord changes resulting from nociceptive afferent bombardment originating in dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

• **Internal thoracic (formerly, mammary) artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[6]

• **Internal thoracic (formerly, internal mammary) vein:** The internal thoracic veins accompany the internal thoracic arteries. The anterior intercostal veins are tributaries of the internal thoracic veins.

• **4th intercostal artery:** Supplies the intercostal muscles, overlying skin, and parietal pleura.

• **4th intercostal vein:** Drains the intercostal muscles, overlying skin, and parietal pleura.

Clinical Relevance: The internal thoracic vessels (formerly known as the internal mammary vessels) represent a continuation from the superior epigastric vessels that also parallel the KI channel. At each intercostal space demarcated by KI 22 to KI 26, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[7]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Insomnia, anxiety, agitation:** KI 23, PC 6, PC 7, HT 3, GV 20.
- **Feeling of fullness in the chest:** KI 23, CV 17, PC 1.
- **Pleuritis, asthma:** KI 23, LU 1, ST 12, ST 13, BL 12, BL 13.
- **Mastitis:** KI 23, ST 18, ST 14, ST 36.

KI 24

Ling Xu "Spirit Hill" or "Spirit Residence"

On the chest, in the 3rd intercostal space, 2 cun lateral to the midline, level with CV 18.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle:** A powerful adductor of the arm. Rotates the humerus in a medial direction.
- **Sternalis muscle:** An inconstant, strap-like muscle that may be unilateral, bilateral, or absent. It joins the rectus abdominis to the sternal head of the sternocleidomastoid muscle. Lies superficial to and fibers run perpendicular to the pectoralis major muscle;[2] parallels the KI channel on either side of the sternum. Historically, the sternalis was considered a variant of the pectoralis major or rectus abdominis muscle. Its innervation varies.

Clinical Relevance: Sternalis trigger points develop anywhere along its course. Symptoms of sternalis trigger points include deep, intense, substernal pain; the sternum itself may become sore. As such, myofascial dysfunction in the sternalis in the region of KI 24 could mimic cardiogenic pain. Components of the referred pain pattern may extend to the ipsilateral PC or HT channel to PC 3 or HT 3.

Nerves

- **3rd intercostal nerve:** Supplies the skin and muscles in this region.
- **Medial pectoral nerve (C7, C8, T1):** Supplies the caudal portion of the pectoralis major as well as the pectoralis minor muscle. May also innervate the sternalis muscle when present.
- **Lateral pectoral nerve (C5-C7):** Supplies the pectoralis major muscle, clavicular and sternal portions. May also innervate the sternalis muscle.

Clinical Relevance: The pectoral nerves exhibit wide variability in their course, origin communications with other nerves, and presence or absence of sensory fibers.[3] They are susceptible to injury from direct trauma, compression from hypertrophied musculature, and iatrogenic injury during mastectomy and breast augmentation. Chronic pain affects up to half of patients undergoing augmentation mammoplasty. The pain centers on the breasts or refers to other regions, including the sternum, infraclavicular tissue, lateral chest wall to the axilla, or interscapular territory on the back.[4] Sternal pain likely results from traction on the lateral pectoral nerve during surgery, given that the nerve supplies both the clavicular and sternal portions of the pectoralis major muscle. Before pursuing invasive methods to treat neuralgia affecting the intercostal or pectoral nerves, acupuncture, manual therapy, and laser therapy (for nonmalignant conditions) should be considered. Caution is warranted, however, with needling near breast implants.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) has the potential to produce chronic pain syndromes: postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[5] The latter condition arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves. The neuromas typically appear on the left intercostal spaces and develop following insertion of sternal wires or needles located at the sternal margin of the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

A wide array of somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27. Figure 8-52. This cross section at KI 24 reveals the relationship between KI 24, the heart (the organ where the spirit supposedly resides), and the internal thoracic vessels, the vascular basis of the KI channel.

Vessels

- **Internal thoracic (formerly, internal mammary) artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[6]
- **Internal thoracic (formerly, internal mammary) vein:** The internal thoracic veins accompany the internal thoracic arteries. The anterior intercostal veins are tributaries of the internal thoracic veins.
- **3rd intercostal artery:** Supplies the intercostal muscles, overlying skin, and parietal pleura.
- **3rd intercostal vein:** Drains the intercostal muscles, overlying skin, and parietal pleura.

Clinical Relevance: The internal thoracic vessels (formerly known as the internal mammary vessels) represent a continuation from the superior epigastric vessels that also parallel the KI channel. At each intercostal space demarcated by KI 22 to KI 26, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[7]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Insomnia, anxiety, agitation:** KI 24, CV 17, BL 14, PC 6, GV 20.
- **Substernal pain that mimics the ache of myocardial infarction or angina pectoris, with a left-sided pattern that can extend to the ulnar aspect of the left forearm and hand:** KI 24, BL 15; check for trigger points in the variable sternalis muscle.

KI 25

Shen Cang "Spirit Storehouse"

On the chest, in the 2nd intercostal space, 2 cun lateral to the midline, level with CV 19.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle:** A powerful adductor of the arm. Rotates the humerus in a medial direction.
- **Sternalis muscle:** An inconstant, strap-like muscle that may be unilateral, bilateral, or absent. It joins the rectus abdominis to the sternal head of the sternocleidomastoid muscle. Lies superficial to and fibers run perpendicular to the pectoralis major muscle;[2] parallels the KI channel on either side of the sternum. Historically, the sternalis was considered a variant of the pectoralis major or rectus abdominis muscle. Its innervation varies.

Clinical Relevance: Sternalis trigger points develop anywhere along its course. Symptoms of sternalis trigger points include deep, intense, substernal pain; the sternum itself may become sore. As such, myofascial dysfunction in the sternalis in the region of KI 25 could mimic cardiogenic pain. Components of the referred pain pattern may extend to the ipsilateral PC or HT channel to PC 3 or HT 3.

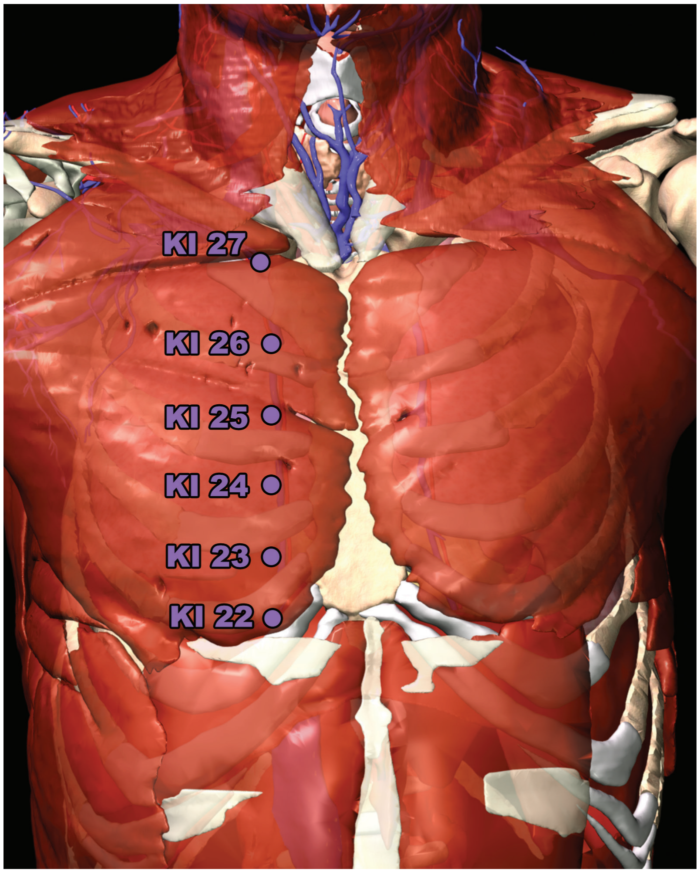

Figure 8-53. KI 25 occupies the 2nd intercostal space. Trigger points in the pectoralis major and sternalis muscles can produce local and referred discomfort similar to angina pectoris symptomatology. This individual lacked an obvious sternalis muscle.

Nerves

- **2nd intercostal nerve:** Supplies the skin and muscles in this region.
- **Medial pectoral nerve (C7, C8, T1):** Supplies the caudal portion of the pectoralis major as well as the pectoralis minor muscle. May also innervate the sternalis muscle when present.
- **Lateral pectoral nerve (C5-C7):** Supplies the pectoralis major muscle, clavicular and sternal portions. May also innervate the sternalis muscle.

Clinical Relevance: The pectoral nerves exhibit wide variability in their course, origin communications with other nerves, and presence or absence of sensory fibers.[3] They are susceptible to injury from direct trauma, compression from hypertrophied musculature, and iatrogenic injury during mastectomy and breast augmentation. Chronic pain affects up to half of patients undergoing augmentation mammoplasty. The pain centers on the breasts or refers to other regions, including the sternum, infraclavicular tissue, lateral chest wall to the axilla, or interscapular territory on the back.[4] Sternal pain likely results from traction on the lateral pectoral nerve during surgery, given that the nerve supplies both the clavicular and sternal portions of the pectoralis major muscle. Before pursuing invasive methods to treat neuralgia affecting the intercostal or pectoral nerves, acupuncture, manual therapy, and laser therapy (for nonmalignant conditions) should be considered. Caution is warranted, however, with needling near breast implants.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) has the potential to produce chronic pain syndromes: postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[5] The latter condition arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves. The neuromas typically appear on the left intercostal spaces and develop following insertion of sternal wires or needles located at the sternal margin of the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. Figure 8-54. "Spirit Storehouse" (KI 25) lives at the level of a vessel epicenter, as shown here.

Vessels

- **Internal thoracic (formerly, internal mammary) artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[6]

- **Internal thoracic (formerly, internal mammary) vein:** The internal thoracic veins accompany the internal thoracic arteries. The anterior intercostal veins are tributaries of the internal thoracic veins.

- **2nd intercostal artery:** Supplies the intercostal muscles, overlying skin, and parietal pleura.

- **2nd intercostal vein:** Drains the intercostal muscles, overlying skin, and parietal pleura.

Clinical Relevance: The internal thoracic vessels (formerly known as the internal mammary vessels) represent a continuation from the superior epigastric vessels that also parallel the KI channel. At each intercostal space demarcated by KI 22 to KI 26, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[7]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Feeling of fullness in the chest, restriction of chest movement:** KI 25, check for other trigger points in the pectoralis major and possibly the sternalis muscle.
- **Cough:** KI 25, BL 12, GB 21, CV 22, LI 4.
- **Intercostal neuralgia:** KI 25, local trigger points above and below the dysfunctional intercostal space.
- **Insomnia, anxiety, agitation:** KI 25, CV 17, BL 14, PC 6, GV 20.

- **Substernal pain that mimics the ache of myocardial infarction or angina pectoris, with a left-sided pattern that can extend to the ulnar aspect of the left forearm and hand:** KI 25; check for trigger points in the variable sternalis muscle.

KI 26

Yu Zhong "Lively Center" or "Chest Comfort"

In the infraclavicular region, in the 1st intercostal space, 2 cun lateral to the midline, level with CV 20.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle:** A powerful adductor of the arm. Rotates the humerus in a medial direction.
- **Sternalis muscle:** An inconstant, strap-like muscle that may be unilateral, bilateral, or absent. It joins the rectus abdominis to the sternal head of the sternocleidomastoid muscle. Lies superficial to and fibers run perpendicular to the pectoralis major muscle;[4] parallels the KI channel on either side of the sternum. Historically, the sternalis was considered a variant of the pectoralis major or rectus abdominis muscle. Its innervation varies.

Clinical Relevance: Sternalis trigger points develop anywhere along its course. Symptoms of sternalis trigger points include deep, intense, substernal pain; the sternum itself may become sore. As such, myofascial dysfunction in the sternalis in the region of KI 26 could mimic cardiogenic pain. Components of the referred pain pattern may extend to the ipsilateral PC or HT channel to PC 3 or HT 3.

Nerves

- **1st intercostal nerve:** Supplies the skin and muscles in this region.
- **Medial pectoral nerve (C7, C8, T1):** Supplies the caudal portion of the pectoralis major as well as the pectoralis minor muscle. May also innervate the sternalis muscle when present.
- **Lateral pectoral nerve (C5-C7):** Supplies the pectoralis major muscle, clavicular and sternal portions. May also innervate the sternalis muscle.

Clinical Relevance: The pectoral nerves exhibit wide variability in their course, origin communications with other nerves, and presence or absence of sensory fibers.[5] They are susceptible to injury from direct trauma, compression from hypertrophied musculature, and iatrogenic injury during mastectomy and breast augmentation. Chronic pain affects up to half of patients undergoing augmentation mammoplasty. The pain centers on the breasts or refers to other regions, including the sternum, infraclavicular tissue, lateral chest wall to the axilla, or interscapular territory on the back.[6] Sternal pain likely results from traction on the lateral pectoral nerve during surgery, given that the nerve supplies both the clavicular and sternal portions of the pectoralis major muscle. Before pursuing invasive methods to treat neuralgia affecting the intercostal or pectoral nerves, acupuncture, manual therapy, and laser therapy (for nonmalignant conditions) should be considered. Caution is warranted, however, with needling near breast implants.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) has the potential to produce chronic pain syndromes: postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[7] The latter condition arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves. The neuromas typically appear on the left intercostal spaces and develop following insertion of sternal wires or needles located at the sternal margin of the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

A wide array of somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27. These problems include costochondritis, physical trauma, upper thoracic somatic

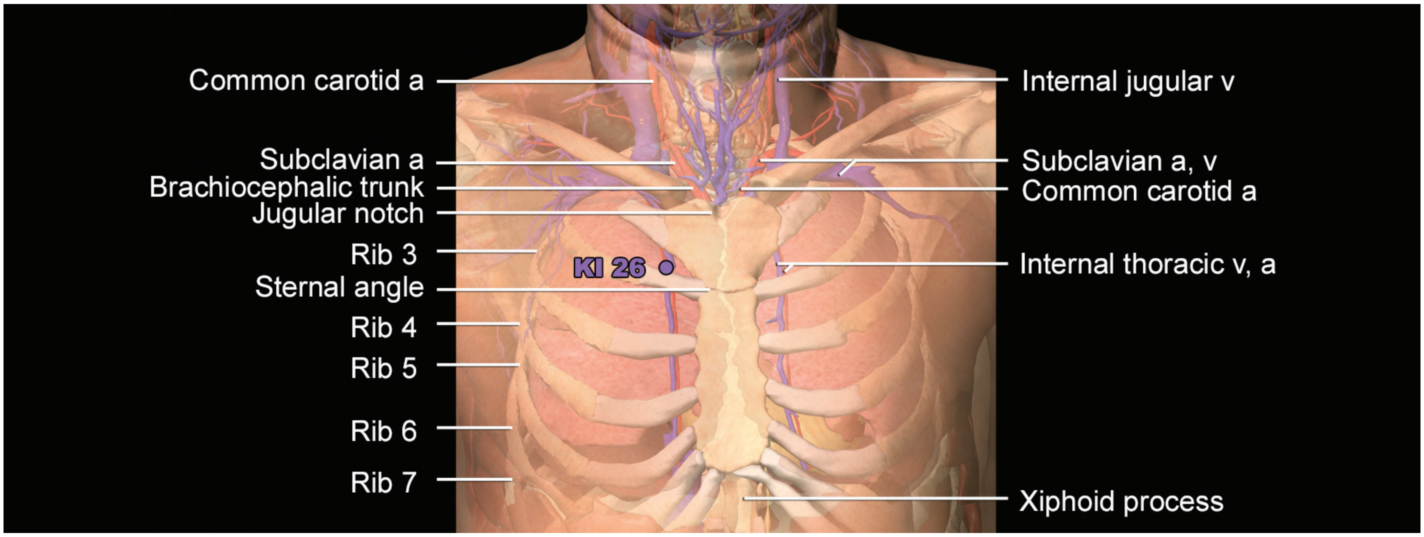

Figure 8-55. The names "Lively Center" and "Chest Comfort" for KI 26 refer to the emotions of tension, anxiety, upset, and psychological pain that afflict the chest.

Figure 8-56. That KI 26 lives on the same level as BL 14 and BL 43 reinforces the emotional and agitation-related perturbations associated with this point. Nearby structures inside the mediastinum such as the esophagus and trachea help explain the indications for KI 26 of dysphagia and cough.

dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Mechanisms involve somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve "unhappiness" as well as upper thoracic spinal cord changes resulting from nociceptive afferent bombardment originating in dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

- **Internal thoracic (formerly, internal mammary) artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery, through its connections to the inferior epigastric artery, provides an avenue for collateral blood supply to a chronically ischemic pelvic limb in cases of aortoiliac occlusive disease.[2,3]

- **Internal thoracic (formerly, internal mammary) vein:** The internal thoracic veins accompany the internal thoracic arteries. The anterior intercostal veins are tributaries of the internal thoracic veins.

- **1st intercostal artery:** Supplies the intercostal muscles, overlying skin, and parietal pleura.

- **1st intercostal vein:** Drains the intercostal muscles, overlying skin, and parietal pleura.

Clinical Relevance: The internal thoracic vessels (formerly known as the internal mammary vessels) represent a continuation from the superior epigastric vessels that also parallel the KI channel. At each intercostal space demarcated by KI 22 to KI 26, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[8]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Fullness, pain, phlegm in chest, cough, asthma:** KI 26, LU 1, LU 2, BL 23, ST 36.
- **Esophageal pain, dysphagia:** KI 26, CV 22, CV 14, ST 36, PC 6.
- **Anxiety,[9] emotional upset, agitation, apprehension:** KI 26, PC 3, PC 7, CV 17, GV 20.

KI 27

Shu Fu "Storehouse Transport"

In a depression inferior to the clavicle near its sternal end, approximately 2 cun lateral to the midline. One can locate 2 cun from the midline by dividing in two the distance between the midline and the midclavicular line.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Platysma muscle:** The platysma muscle arises in the fascia covering the deltoid and pectoralis major muscles. These fibers sweep over the clavicle to insert on the inferior border of the mandible. Cutaneous nerves pierce the platysma muscle. When contracted, the playsma conveys expressions of tension, stress, or a grimace.
- **Pectoralis major muscle:** A powerful adductor of the arm. Rotates the humerus in a medial direction.
- **Subclavius muscle:** Depresses and anchors the clavicle, which helps stabilize the clavicle during arm movements.

Clinical Relevance: A myofascial trigger point in the subclavius muscle directly coincides with KI 27. This common but under recognized source of subclavicular and thoracic limb discomfort refers pain from the clavicle to the biceps region, the radial aspect of the antebrachium, and both dorsal and palmar surfaces of the hand, including the thumb, index, and middle fingers. The course of the pain pattern overlaps the LU and LI channel routes.

Figure 8-57A reveals how the platysma muscle attaches to the infraclavicular region, predisposing patients to attachment trigger points. It also indicates the intersection of KI 27 at the border of the adjacent sternal and clavicular parts of the pectoralis muscle.

Nerves

- **Supraclavicular nerves (C3, C4):** Supply the skin over the shoulder and clavicle.
- **1st thoracic intercostal nerve:** Supplies the skin over this region.
- **Cervical branch of the facial nerve (CN VII):** Innervates the platysma muscle.
- **Nerve to the subclavius (C5 and C6):** Supplies the subclavius muscle.
- **Medial pectoral nerve (C7, C8, T1):** Supplies the caudal portion of the pectoralis major as well as the pectoralis minor muscle. May also innervate the sternalis muscle when present.
- **Lateral pectoral nerve (C5-C7):** Supplies the pectoralis major muscle, clavicular and sternal portions. May also innervate the sternalis muscle.

Clinical Relevance: The pectoral nerves exhibit wide variability in their course, origin communications with other nerves, and presence or absence of sensory fibers.[2] They are susceptible to injury from direct trauma, compression from hypertrophied musculature, and iatrogenic injury during mastectomy and breast augmentation. Chronic pain affects up to half of patients undergoing augmentation mammoplasty. The pain centers on the breasts or refers to other regions, including the sternum, infraclavicular tissue, lateral chest wall to the axilla, or interscapular territory on the back.[3] Sternal pain likely results from traction on the lateral pectoral nerve during surgery, given that the nerve supplies both the clavicular and sternal portions of the pectoralis major muscle. Before pursuing invasive methods to treat neuralgia affecting the intercostal or pectoral nerves, acupuncture, manual therapy, and laser therapy (for nonmalignant conditions) should be considered. Caution is warranted, however, with needling near breast implants.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) has the potential to produce chronic pain syndromes: postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[4] The latter condition arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves. The neuromas typically appear on the left intercostal spaces and develop following insertion of sternal wires or needles located at the sternal margin of the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

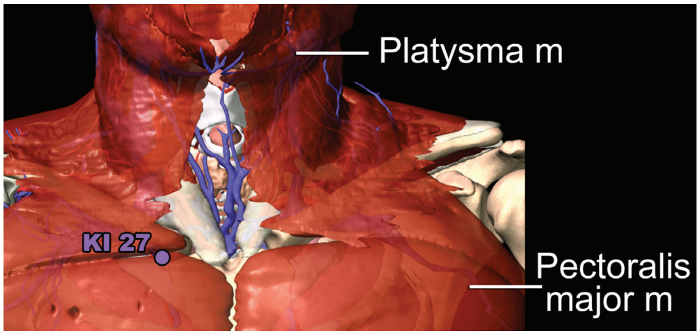

Figure 8-57A. Palpating KI 27 frequently elicits reports of tenderness, considering the various pulls on the site from the attachments of the platysma as well as the clavicular and sternal attachments of the pectoralis muscle.

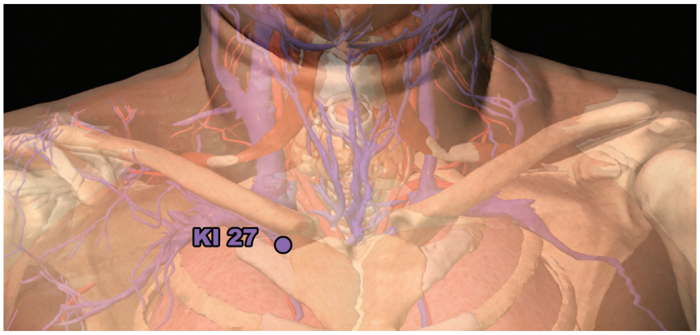

Figure 8-57B. "Storehouse Transport" metaphorically connects the "Storehouse" (heart) with its vascular conduits. Note how the subclavian, brachiocephalic, and internal thoracic vessels intersect at KI 27.

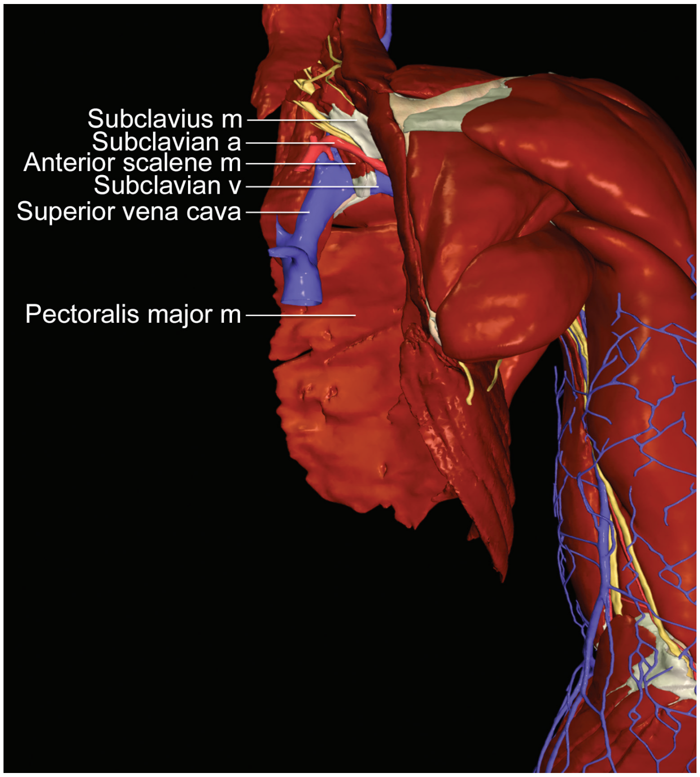

Figure 8-58A. This "view from the inside" of the chest wall provides a "behind the scenes" look of the muscular, vascular, and neural structures caudal to KI 27.

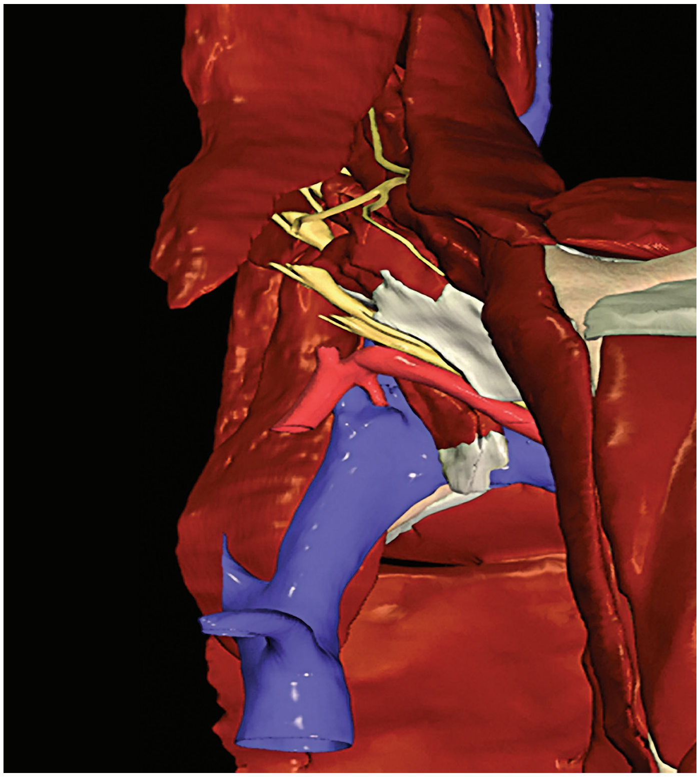

Figure 8-58B. The image provides a close-up view of the structures deep to KI 27, labeled in Figure 8-58A.

A wide array of somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27. These problems include costochondritis, physical trauma, upper thoracic somatic dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Mechanisms involve somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve "unhappiness" as well as upper thoracic spinal cord changes resulting from nociceptive afferent bombardment originating in dysfunctional organs, muscles, tendons, or nearby tissues.

Treatment with acupuncture at KI 27, at the cranial limit of the KI channel, may benefit patients with thoracic outlet syndrome. View a portion of the region affected in these patients in Figure 8-58. These patients typically describe pain, paresthesias, swelling, weakness of the thoracic limb, and color changes in that limb when they carry objects overhead or that are heavy.[5] Compression of neurovascular structures in the cervical and axillary region precipitates this condition. Etiologies include anatomic anomalies such as the presence of a cervical rib, long transverse process of C7, congenital bands, and aberrant musculature such as a subclavius posticus muscle.

Clavicular fracture and post-traumatic scarring may produce supraclavicular nerve entrapment,[6] along with compression of the nerve to the subclavius muscle. Neurogenic thoracic outlet syndrome can also follow neck trauma and first rib fracture.[7]

Vessels

- **Internal thoracic (formerly, internal mammary) artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries.
- **Internal thoracic (formerly, internal mammary) vein:** The internal thoracic veins accompany the internal thoracic arteries. The anterior intercostal veins are tributaries of the internal thoracic veins.

Clinical Relevance: The internal thoracic vessels (formerly known as the internal mammary vessels) represent a continuation from the superior epigastric vessels that also parallel the KI channel. At each intercostal space demarcated by KI 22 to KI 26, the internal thoracic vessels connect to the intercostal arteries and veins. At KI 27, the internal thoracic artery arises from the subclavian artery near its origin while its venous partner terminates in the brachiocephalic vein. By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[8]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing

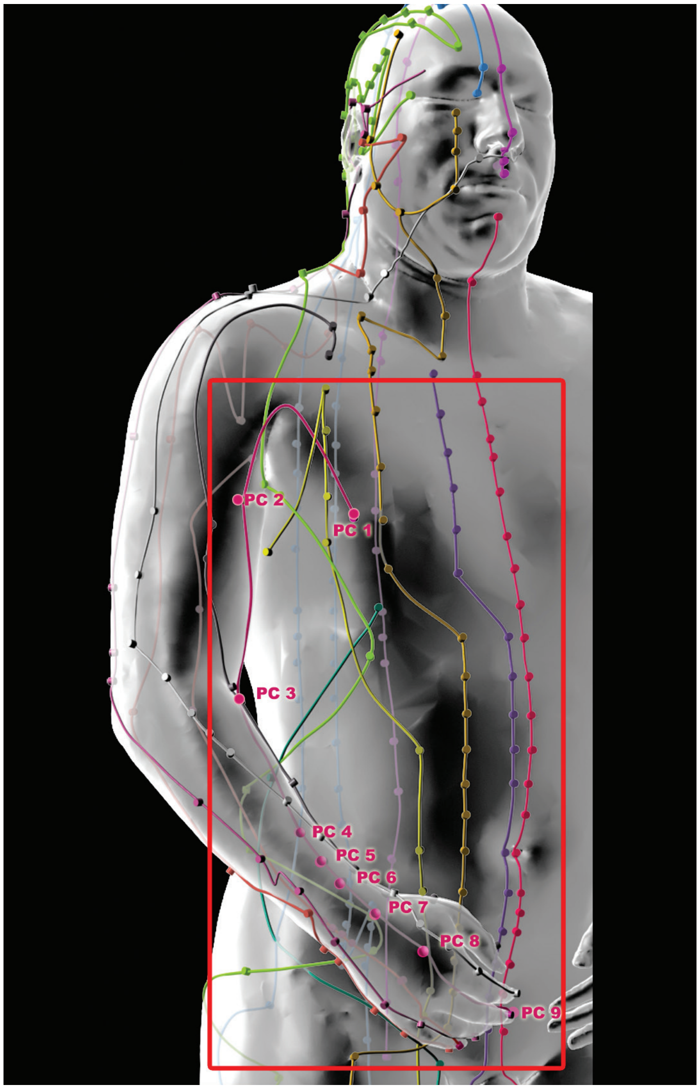
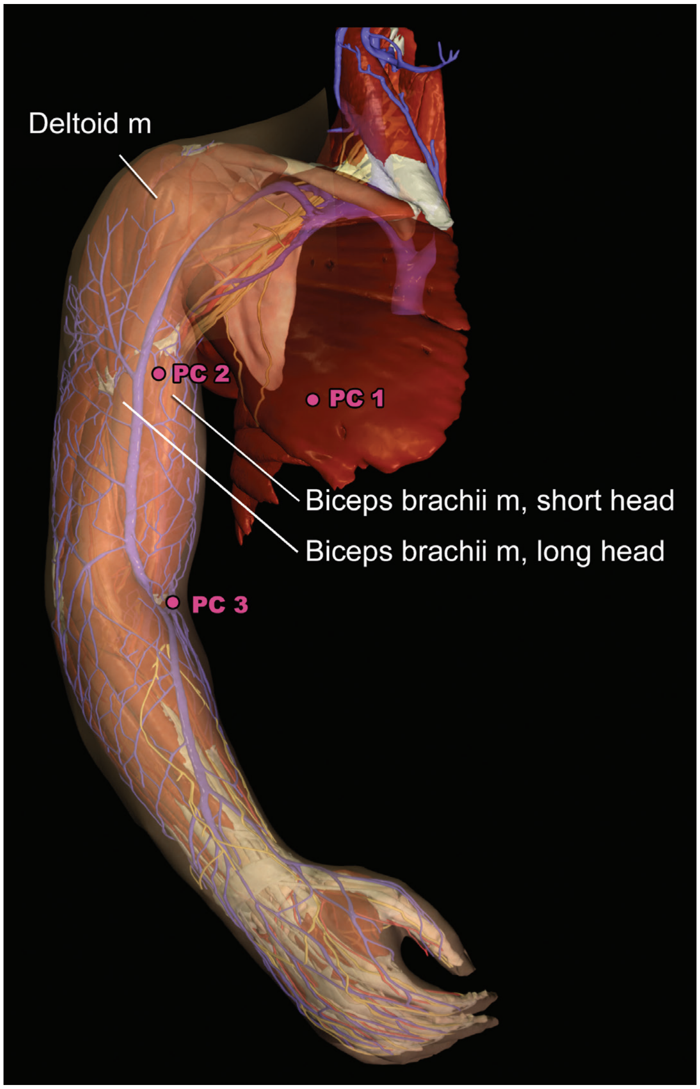
Channel 9:: The Pericardium (PC)



PC 2
PC 1
PC 3
PC 4
PC 5
PC 6
PC 7
PC 8
PC 9

The PC channel begins lateral to the nipple in the 4th intercostal space. It ascends to the anterior axilla then descends down the medial aspect of the biceps brachii muscle. Distal to the elbow, the PC channel tours the interosseous groove along the palmar antebrachial surface. It makes its way across the palm between the 2nd and 3rd metacarpal bones. Where the channel ends at PC 9 has raised debate, with some placing it on the radial nail angle of the dorsal middle finger. Others end the channel at the midpoint of the fingertip. In this image, the distal PC channel, coursing on the palmar antebrachium, appears through translucent distal limb and emerges at the tip of the middle finger.



Deltoid m
PC 2
PC 1
Biceps brachii m, short head
Biceps brachii m, long head
PC 3

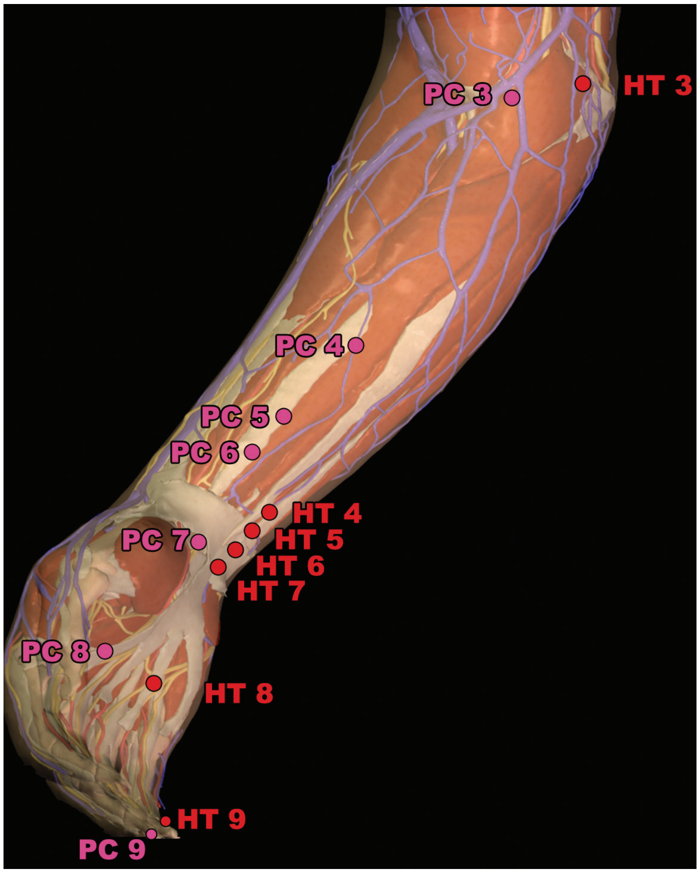
This image illustrates the relationship between the first three PC points and the muscular anatomy of the thoracic limb.

One can identify connective tissue connections, or trains, that follow acupuncture channels in addition to neurovascular passageways.[4] Myofascial chains, trains, or interlocking fascial planes participate in similar directional movements, supporting a structure-function relationship. Expansions of muscle into fascia create a vehicle for bidirectional communication and reciprocal feedback between fascia and muscles. That is, fascia can perceive and diffuse tension in a muscle or from muscle groups. Muscle spindle activation informs the central nervous system about the state of contraction not only of the muscle it supplies but also attaching fascia.

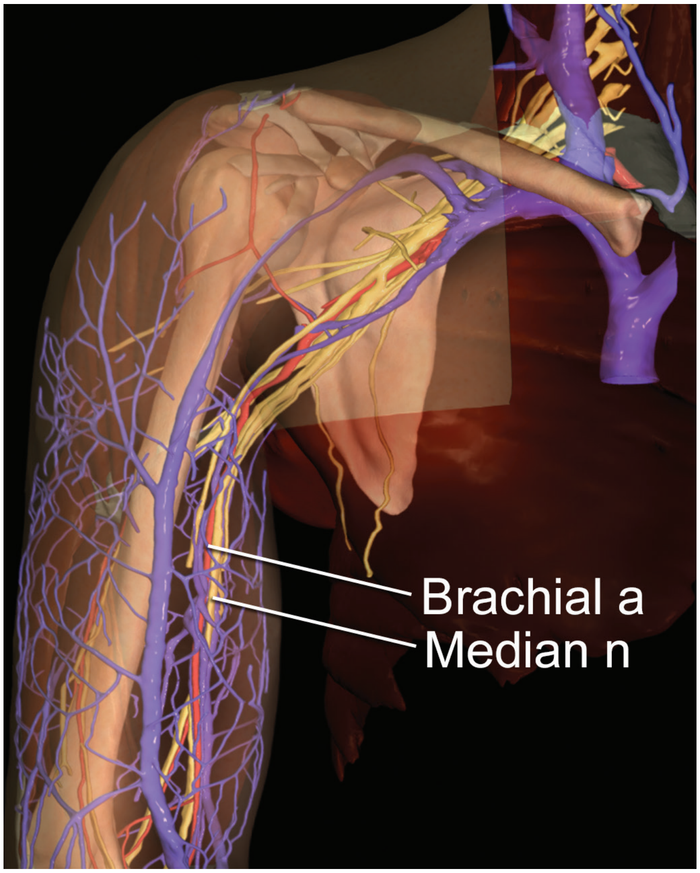
While these myofascial continua usually do not define the channel trajectories precisely or *in toto,* they lend insight into why individuals report sensations of pulling, traveling, and tissue release during needle stimulation. Their innervation reinforces the neuroanatomic basis of the channel. For the PC channel, its closest soft tissue continuum connects the pectoralis major, biceps brachii, bicipital aponeurosis/lacertus fibrosus, and palmaris longus muscles.

For example, contracting pectoralis major fibers (affected by PC 1), particularly from the clavicular portion (KI 27, the end of the KI channel that connects to the beginning of the PC channel at PC 1), stretch the brachial fascia through its expansions onto the cranial aspect of the brachium (PC 2). Elbow flexion by means of biceps brachii contraction tenses the bicipital aponeurosis (PC 3), thereby stretching antebrachial fascia (PC 4, 5). With wrist flexion, the palmaris longus (when present, adjacent to PC 6) tenses the flexor retinaculum (PC 7), palmar aponeurosis (PC 8), and thenar fascia (extending to PC 9).

These lines of force generate a conduit that "pulls together" myofascial components of the PC channel, providing feedback to the nervous system through mechanoreceptors immersed in fibrous stroma concerning movement patterns, directions of force, and amount of tension in the system. This extensive network of information housed within the soft tissues prevents over-maximal stretch

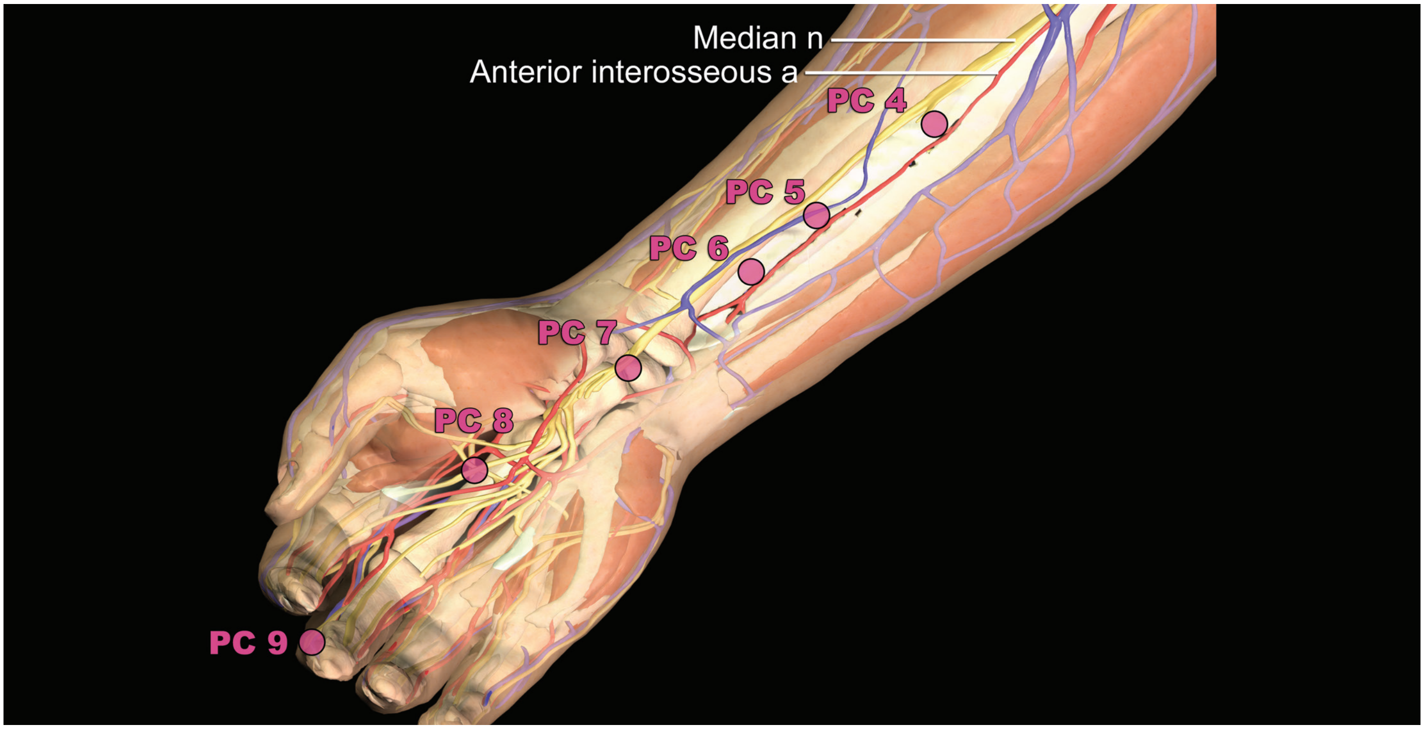


The PC channel parallels the HT channel in terms of trajectory, numbering, and certain clinical applications related to the heart, spirit, and psyche.[1] Anatomically, the heart and its enveloping pericardium exhibit intimately connections as well.



The neurovascular basis of the HT and PC channels closely relate, in keeping with the similarity of their trajectories and numbering. As shown by this image, the brachial artery (vascular basis of the HT channel) and median nerve (representing the PC pathway) course to the elbow side by side. Furthermore, while the median nerve provides no voluntary motor or cutaneous function to the brachium, it does supply sympathetic branches to the brachial artery as nervi vasorum.

The musculocutaneous nerve, truncated in this depiction, also associates with the PC channel in the brachium, in that it supplies the biceps brachii muscle; PC 2 nestles between its short and long heads. The musculocutaneous and median nerves sometimes form plexuses in the brachium. Their communicating branches can reach down to the elbow.[2,3]



Distal to the elbow, PC sticks with the median nerve and its vascular partner, the anterior interosseous artery. Research on PC points of the antebrachium verifies their physiologic effects as arising from neuromodulation of the median nerve.[5,6,7]

or contraction that could injure the individual. In contrast, in cases of abnormal fascial feedback, central and peripheral nervous system sensitization, or decreased myofascial elasticity, self-monitoring may falter, manifesting as injury or pain as tissues become overstretched or overstrained. In addition, patients with pre-existing spinal cord "wind-up" tend to emit excessive volleys of motor neuron stimulation to the muscles, keeping them in sustained states of tension. Furthermore, tension held within the myofascia due to unhealthful loss of elasticity or the inability to psychologically or physically relax can activate fascial receptors. Incessant stimulation of afferents causes connective tissue sensors to remain in a heightened state of activity even when the individual is still or asleep. Over time, allodynia ensues and mechanoreceptors acquire nociceptive function. By then, even normal physiologic stretch on a soft tissue plane or system may induce discomfort and initiate or aggravate myofascial pain syndromes.

PC 1

Tian Chi "Celestial Pool" or "Heavenly Pool"

On the chest, in the 4th intercostal space, approximately 1 cun lateral to the nipple.

(Alternate location: the most sensitive site palpated immediately medial to the anterior axillary crease.)

Caution: Deep needling at PC 1 may cause pneumothorax.

Muscles

- **Pectoralis major muscle:** A powerful adductor of the arm. Rotates the humerus in a medial direction.
- **Pectoralis minor muscle**: Stabilizes the scapula by holding it anteriorly against the thoracic wall and by drawing it inferiorly.

Clinical Relevance: Pectoralis minor trigger points in the vicinity of PC 1 radiate diffusely over the pectoralis major region, the deltoid, and the PC and HT trajectories. Trigger point pathology in the sternal section of the pectoralis major muscle near PC 1 send pain to the pectoral region, PC and HT lines to the elbow, and the proximoulnar elbow region. Trigger point pathology along the lateral margin of the pectoralis can refer pain strongly to the central breast and nipple, extending from PC 1 to PC 2.

Nerves

- **4th intercostal nerve:** Supplies the skin and muscles in this region.
- **Medial pectoral nerve (C7, C8, T1):** Supplies both the pectoralis minor and major muscles.
- **Lateral pectoral nerve (C5-C7):** Supplies the pectoralis major muscle.

Clinical Relevance: The pectoral nerves exhibit wide variability in their course, origin communications with other nerves, and presence or absence of sensory fibers.[1] They are susceptible to injury from direct trauma, compression from hypertrophied musculature, and iatrogenic injury during mastectomy and breast augmentation. Chronic pain affects up to half of patients undergoing augmentation mammoplasty. The pain centers on the breasts or refers to other regions, including the sternum, infraclavicular tissue, lateral chest wall to the axilla, or interscapular territory on the back.[2] Sternal pain likely results from traction on the lateral pectoral nerve during surgery, given that the nerve supplies both the clavicular and sternal portions of the pectoralis major muscle. Before pursuing invasive methods to treat neuralgia affecting the intercostal or pectoral nerves, acupuncture, manual therapy, and laser therapy (for nonmalignant conditions) should be considered. Caution is warranted, however, with needling near breast implants.

A wide array of somatic and visceral sources of dysfunction can cause tenderness to palpation in the region of PC 1. Mechanisms involve somato-somatic and viscerosomatic reflexes as well as

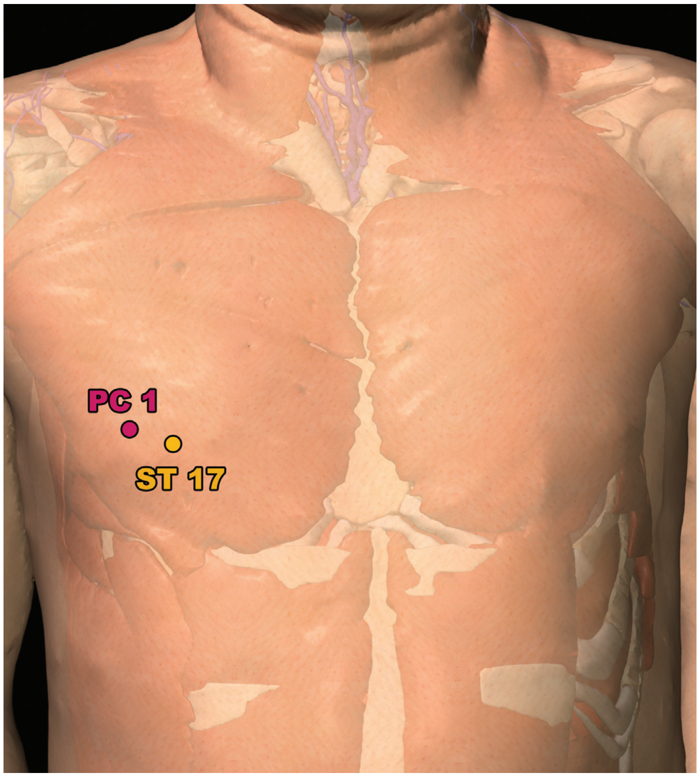

Figure 9-1. PC 1, "Celestial (Heavenly) Pool" couples an allusion to the upper part of the body (the sky) with the concept that milk pours out of the nipple (at ST 17) from an adjacent pool (PC 1).

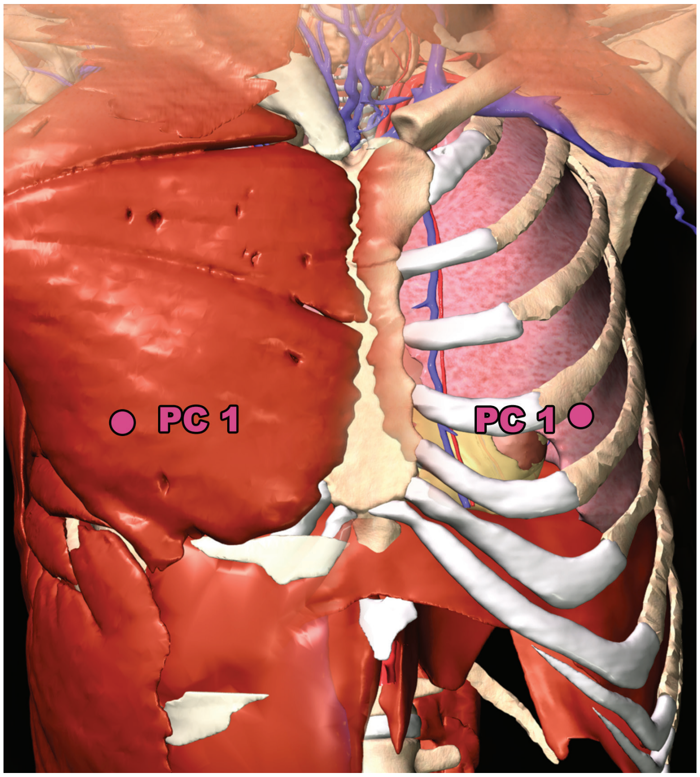

Figure 9-2. One needs to remain mindful of the underlying breast and lungs when needling PC 1, as illustrated here. Ideally, one should avoid needling through the female breast to reach the pectoralis muscle. In cases of pectoralis trigger points requiring treatment, judiciously applied manual therapy, gentle heat, or other measures are safer and usually better received.

Figure 9-3. Between the breast and the lung, potentially troublesome trigger points in the pectoralis major (and minor) could cause confusing chest and axillary pain. Palpating carefully to determine the presence of trigger points and the source(s) of referred pain can lend insight into a myofascial provocation of otherwise potentially alarming chest pain.

irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve "unhappiness" as well as upper thoracic spinal cord changes resulting from nociceptive afferent bombardment originating in dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

- **Lateral thoracic (formerly, external mammary) artery and vein:** Supply and drain, respectively, the lateral thorax and breast. Also extend branches to the serratus anterior and pectoralis major muscle, serratus anterior muscles, the subscapularis muscle, and the axillary lymph nodes. These vessels anastomose with the internal thoracic, subscapular, and intercostal vessels as well as the pectoral branch of the thoracoacromial artery.

Clinical Relevance: The lateral thoracic artery and vein provide an external mammary branch that rounds the edge of the pectoralis major muscle and supplies and drains the breast. Compression of these vessels may compromise oxygenation, nutrition, and elimination of metabolic waste products from the mammary tissue.

Indications and Potential Point Combinations

- **Strong emotional states:** PC 1, CV 17, HT 7, ST 36.
- **Pain in the breast, shoulder, and medial brachial region, potentially radiating to the medial proximal antebrachium from trigger points in the intermediate sternal section of the pectoralis major muscle:** PC 1, local trigger points in the pectoralis major and/or minor muscles, LU 1, HT 3.
- **Intercostal pain in the 4th intercostal space:** PC 1, BL 14, BL 15, CV 17, other local trigger points.
- **Pain and swelling in the axilla related to serratus anterior muscle trigger points:** PC 1, consider GB 22, GB 23, medial scapular border trigger points in the vicinity of BL 16, BL 17, where the serratus anterior attaches and pulls.

PC 2

Tian Quan "Celestial Spring" or "Heavenly Spring"

On the anterior brachium, 2 cun distal to the end of the anterior axillary fold, between the two heads of the biceps brachii muscle.

Muscles

- **Biceps brachii muscle:** The biceps brachii muscle supinates and then flexes the forearm.
- **Brachialis muscle:** Flexes the forearm.
- **Coracobrachialis tendon:** Assists in arm flexion and adduction.

Clinical Relevance: Tension in the proximal brachium may respond to treatment at PC 2; depending on the depth and angle of the needle and muscles affected. See Figure 9-6 for more information. Proximal to the elbow, the coracobrachialis muscle may entrap the musculocutaneous nerve proximal to the elbow.[1] PC 2 is located where the musculocutaneous nerve pierces the coracobrachialis muscle. As such, treating PC 2 may address neuromuscular dysfunction or nerve entrapment.[2]

The V-like depression between the short and long heads of the biceps brachii muscle often exhibits tenderness to palpation.

Schematic mapping of biceps brachii motor points explains the sensitivity felt at the juncture of the short and long heads, indicating where dysfunctional motor endplates (i.e., contributors to trigger point formation) from the musculocutaneous nerve reside.[3]

Nerves

- **Medial brachial cutaneous nerve (C8, T1):** Supplies the skin on the medial brachium (arm).
- **Musculocutaneous nerve (C5-C7):** Supplies the coracobrachialis, biceps brachii, and brachialis muscles. Courses with the basilic vein; sends branches to the skin of the medial brachium. Several branches pierce the fascia to supply the skin proximal to the medial epicondyle. Continues as the lateral antebrachial cutaneous nerve.

Clinical Relevance: Excessive tension in the brachial flexors (biceps brachii, brachialis, or coracobrachialis muscles) from strenuous physical activity or contracture may compress the musculocutaneous nerve.

Communication between the median and musculocutaneous nerves is fairly common but unpredictable. These connections occur proximal or distal to the coracobrachialis muscle or sometimes within the structure.[4] Unpredictable neuroanatomy elevates the risk of nerve injury during shoulder surgery or other plastic and reconstructive repair procedures. Entrapment syndromes can arise as a result of scarring and contracture,[5] as has been reported following biceps tenodesis.[6]

Brachioplasty surgery, i.e., provided for patients undergoing bariatric surgery procedures to manage excess skin on the arm from massive weight loss, can injure the medial brachial cutaneous nerve.[7]

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median

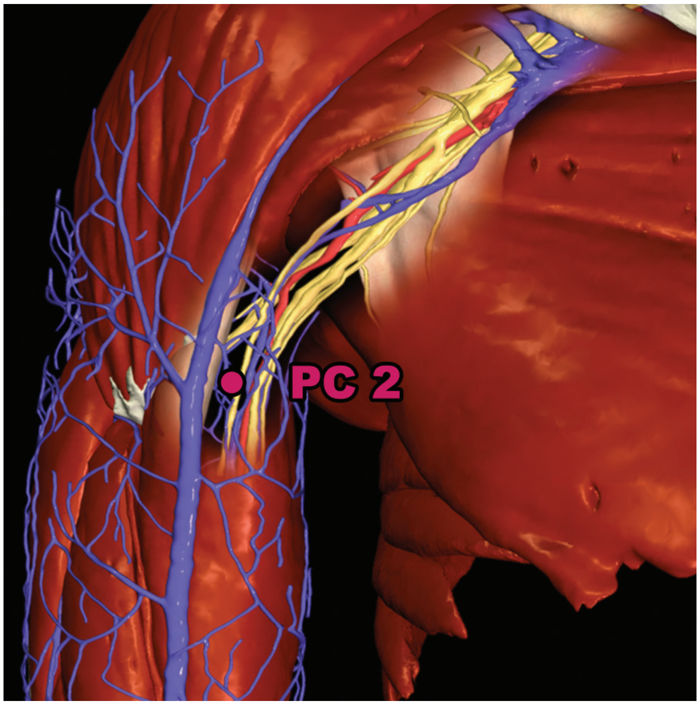

Figure 9-4. PC 2 sits between the short and long head of the biceps brachii muscle, and as seen here, atop a bundle of prominent neurovascular structures. Communications between the musculocutaneous and median nerves at times take place here.

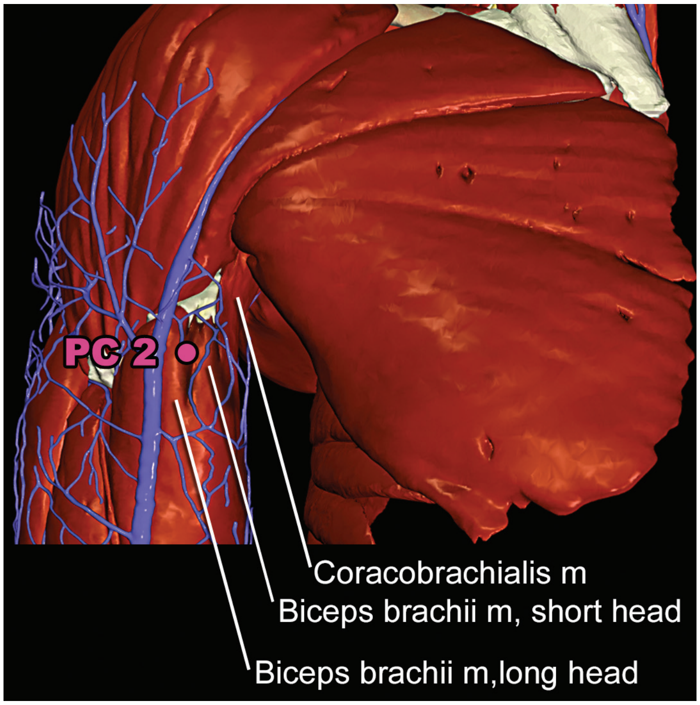

Figure 9-5. The descriptive term for PC 2, "Celestial Spring", connotes a continuation of flow from PC 1, "Celestial Pool".

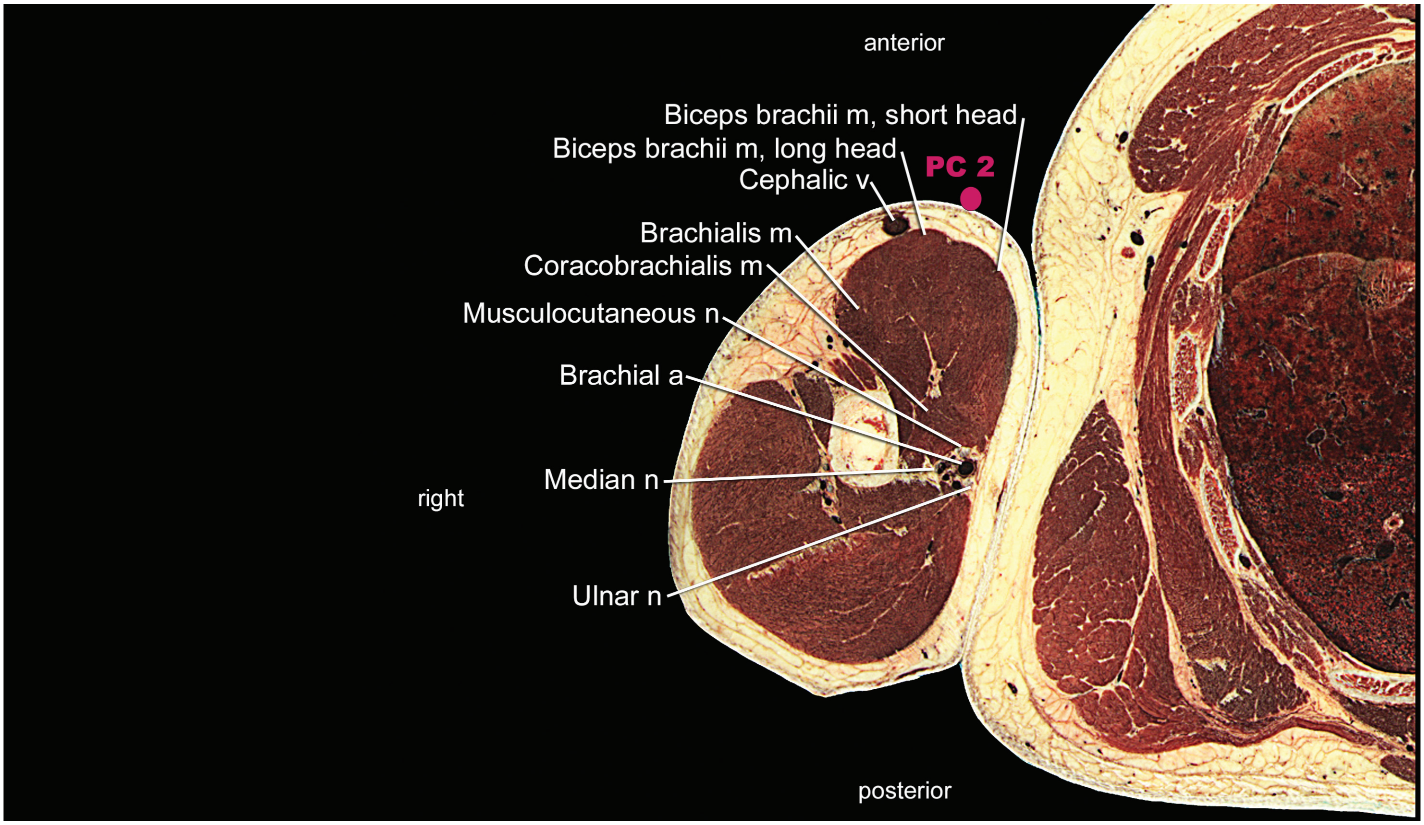

Figure 9-6. This cross-section reveals the abundant muscle tissue available at PC 2 for trigger point deactivation. Note the depth and direction required for a needle to reach myofascial dysfunction in the short or long head of the biceps brachii or coracobrachialis.

cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.

Brachial artery: A continuation of the axillary artery, the brachial artery provides the main arterial supply to the arm. The brachial artery gives rise to the radial and ulnar arteries. Other main branches include the deep artery of the arm (profunda brachii artery) and the superior and inferior ulnar collateral arteries, which help form the elbow arterial anastomoses. The median nerve accompanies the brachial artery as it courses along the brachium.

- **Brachial veins:** The brachial veins accompany the brachial artery and frequently encompass it, forming a common vascular sheath by means of their anastomotic interconnections. Blood draining from the brachial vein is further pushed along its pathway by the brachial artery's pulsations. The brachial veins form from the veins which travel with the radial and ulnar arteries. They drain into the axillary vein after joining with the basilic vein.

Clinical Relevance: The arterial patterns of the thoracic limb vary widely. Lack of awareness of possible variations can complicate surgery with ischemia or hematoma. Unusual vascular patterns of the hand could pose problems following injection where local necrosis and ischemia could occur.[8]

Indications and Potential Point Combinations

- **Chest pain:** First, ensure that proper medical measures to rule out a cardiac source have taken place. For chest pain of referred musculoskeletal origin from the subclavius muscle, consider PC 2, in addition to the subclavius trigger point at KI 27, in addition to distal points along the LU line to the fingertips. Triggers from the clavicular section of the pectoralis major muscle, at LU 1 and LU 2, may refer pain to the deltoid region ant PC 2.
- **Cough:** PC 2 if the cough generates pull on the biceps brachii muscle in this region. Consider adding CV 22, LU 1, LI 11, GV 14, BL 23.
- **Arm pain related to the biceps brachii[9] and brachialis muscles:** PC 2, PC 3, LU 3, LU 4, local trigger points.
- **Shoulder restriction:** PC 2, LU 15, TH 14, trigger points as required.

PC 3

Qu Ze "Marsh at the Crook"

On the cubital crease, on the ulnar side of the biceps brachii tendon, just medial to the pulsation of the brachial artery. Locate with the elbow slightly flexed.

Fascia

- **Bicipital aponeurosis or lacertus fibrosus:** This triangular, membranous band forms a distal continuation of the biceps brachii muscle. It courses from the biceps tendon, across the cubital fossa, to blend with the deep antebrachial fascia, blanketing the flexor muscles of the forearm. The proximal end of the lacertus fibrosus, closer to the biceps tendon, is palpable as it courses obliquely over the brachial artery and median nerve. The lacertus protects this neurovascular couple from trauma; it also dissipates load away from the biceps tendon entheses, reducing pull on the radial biceps tendon.[1]

Clinical Relevance: Excessive tension in the lacertus fibrosus could compress the median nerve and brachial artery.[2] Acute, partial rupture of the myotendinous junction of the biceps brachii can also increase compression of the median nerve by a tethered lacertus fibrosus.[3] Repair of the lacertus after rupture may compress the median nerve if the width or length of the lacertus becomes too short.[4]

Acupuncture at PC 3, along with laser therapy and soft tissue manual treatment for a restrictive lacertus fibrosus in order to lessen pressure on the median nerve and brachial vessels.

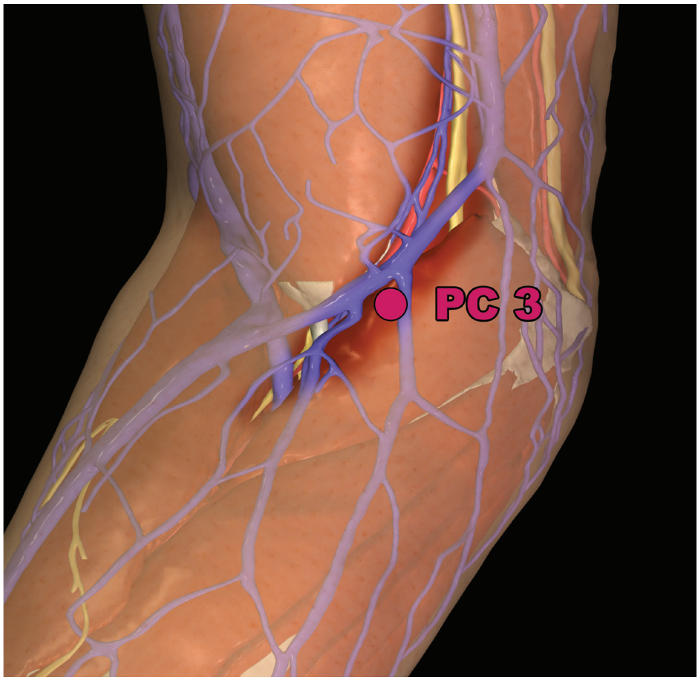

Figure 9-7. The wide, shallow, "Marsh at the Bend" known as PC 3, shows itself best with the elbow partially flexed. The metaphor of a "marsh" connotes a boggy, soft, fluid-filled feel to PC 3 when palpating the region. By creating a window in the muscle layer at the medial elbow shown here, one can examine the neurovascular structures responsible for generating tenderness and fullness. They include the brachial artery, accompanying veins, basilic vein, and the myofascial cleavage plane medial to the distal tendon of the biceps brachii muscle.

Muscles

- **Biceps brachii muscle:** The biceps brachii muscle supinates and then flexes the forearm. Both heads (the short and long) coalesce into a single distal tendon that inserts on the ulnar aspect of the bicipital tuberosity of the radius.[10]
- **Brachialis muscle:** Flexes the forearm.

Clinical Relevance: Tendon degeneration and compromised circulation may precipitate rupture or avulsion of the distal biceps tendon.[11] Surgical repair may be supported by acupuncture and related techniques, improving circulation and tissue recovery. An incompletely ruptured distal tendon of the biceps at its insertion can compress the median nerve by the lacertus fibrosus. Patients with partial tendon rupture also typically exhibit the formation of a cyst or hematoma, along with proximal biceps muscle bulge and elongation of the distal tendon. Partial rupture of the distal biceps brachii tendon has been reported to compress the median nerve and anterior interosseous vessels, secondary to development of a large synovial bursa.[12]

Treatment of myofascial dysfunction of the elbow should be treated first with acupuncture and related techniques, as trigger point injection introduces risk of myositis ossificans as well as other problems related to inserting medications deep into the elbow, potentially inciting tissue reactions.[13] In addition, the beveled tip of a hypodermic needle can lacerate one or more of the many vessels anastomosing here, leading to hemorrhage, vascular stasis, tissue hypoxia, and release of calcium from muscle, i.e., factors that induce myositis ossificans.

Nerves

- **Medial brachial cutaneous nerve (C8, T1):** Supplies the skin on the medial brachium (arm).
- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm.
- **Musculocutaneous nerve (C5-C7):** Supplies the coracobrachialis, biceps brachii, and brachialis muscles. Courses with the basilic vein; sends branches to the skin of the medial brachium. Several branches pierce the fascia to supply the skin proximal to the medial epicondyle. It continues as the lateral antebrachial cutaneous nerve.
- **Median nerve (C6-T1):** Accompanies the brachial artery along the arm but supplies no branches except for some small twigs to the brachial artery. The median nerve does supply articular branches to the elbow as it courses past the joint. Muscular branches supply the pronator teres and pronator quadratus muscles and all of the forearm flexors (including the flexor carpi radialis, the palmaris longus, and the flexor digitorum superficialis muscles), except the flexor carpi ulnaris and medial half of the flexor digitorum profundus muscle.

Clinical Relevance: Brachioplasty surgery, i.e., provided for patients undergoing bariatric surgery procedures to manage excess skin on the arm from massive weight loss, can injure the medial brachial cutaneous nerve.[14]

Women with macromastia may exhibit neurologic deficits in function of the medial antebrachial cutaneous nerve and median nerve due to chronic bilateral T1 denervation.[15] Somatic dysfunction of the spine can complicate the identification of

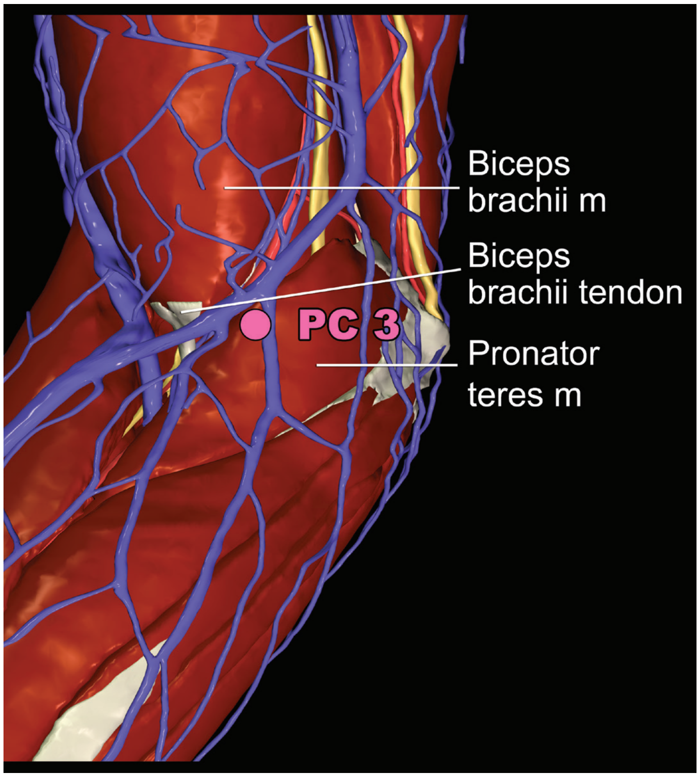

Figure 9-8. This medial view of the right elbow illustrates how PC 3 relates to the biceps brachii tendon, the pronator teres muscle and the lacertus fibrosus, not shown here. The lacertus fibrosus crisscrosses the pronator teres and lies superficial to it.

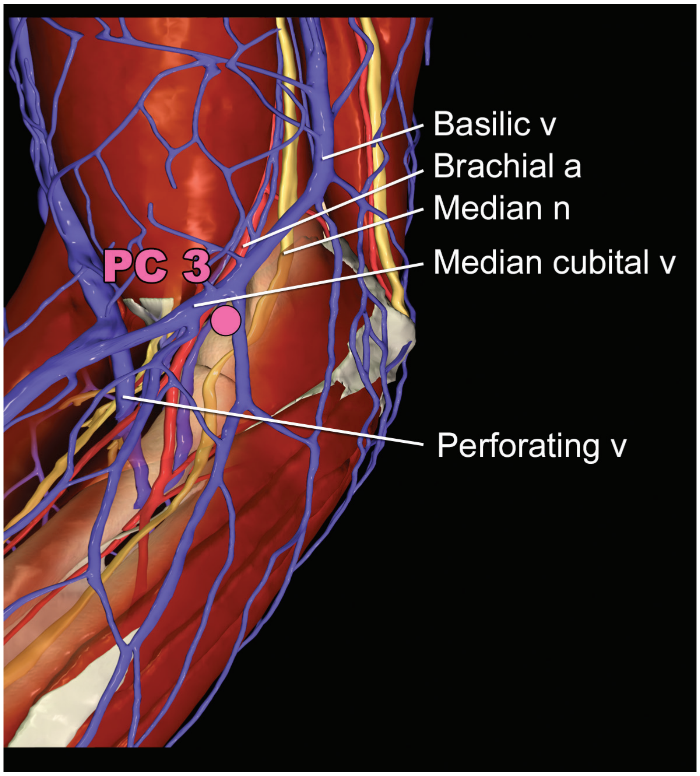

Figure 9-9. This depiction reveals the busy neurovascular traffic coursing along the PC channel and inhabiting PC 3.

neuropathic pain and dysesthesia; upper thoracic radiculopathy can produce thoracic limb pain.[16]

Musculocutaneous nerve compression may arise from an injury following hyperextension and pronation; it typically produces pain and paresthesias that radiate along the radial aspect of the antebrachium.[17]

Communication between the median and musculocutaneous nerves is fairly common but unpredictable. These connections occur proximal or distal to the coracobrachialis muscle or sometimes within the structure.[18] Unpredictable neuroanatomy elevates the risk of nerve injury during shoulder surgery or other plastic and reconstructive repair procedures. Entrapment syndromes can arise as a result of scarring and contracture,[19] as has been reported following biceps tenodesis.[20]

Regardless of the nerve undergoing compression or entrapment, conservative treatment with physical medicine measures should reduce or eliminate symptoms of decreased sensation and motor weakness, ideally implemented well in advance of the need for surgery.

The median nerve may face compression by several structures along its route in addition to those at the carpal tunnel. Potential sources of compression include the lacertus fibrosus, ligament of Struthers, the two heads of the pronator teres between which it may course, anomalous muscles such as the accessory head of the flexor pollicis longus muscle (known as Gantzer's muscle), and the sublime bridge.[5]

Sources of nerve compression also obstruct blood vessels that supply and drain the nerves. This reduces venous return and thereby invites edema, capillary vasodilation, and segmental anoxia.[21] The presence of edema furthers the compression, causing abnormalities in axonal and cellular communication.

In addition to nerve compression, myofascial dysfunction or fibrous restriction may tether a nerve, thereby limiting its mobility. Joint motion places traction on the nerves, sometimes producing a block in nerve conduction. Median nerve compression syndromes often involve traction as a pathophysiologic component.

By the time the median nerve reaches PC 3, it may have undergone compression by the ligament of Struthers, a ligament that extends from the supracondylar ridge of the humerus to the medial epicondyle, forming a bridge or arcade over the median nerve. Just distal to PC 3 on the proximal antebrachium, the median nerve may suffer compression by the superficial and deep heads of the pronator teres muscle. At this same section of the forearm, the anterior interosseous nerve branches from the median to travel along the interosseous groove between the radius and ulna. It, too, can experience compression or tethering from the pronator teres and fibrous arcade of the flexor digitorum superficialis muscles.

By reaching from the interosseous region of the mid-forearm to the medial epicondyle of the humerus, the enigmatic "Gantzer's muscle", or accessory head of the flexor pollicis longus muscle can compress both structures, i.e., the anterior interosseous and median nerves. This happens between PC 3 and PC 4. From PC 4 to PC 5, an aberrant flexor carpi radialis brevis or palmaris profundus muscle may harm the anterior interosseous nerve.

Right at PC 3, the lacertus fibrosus can place abnormal pressure on both the brachial artery and median nerve within or distal to the cubital fossa as the lacertus courses mediad to insert on the

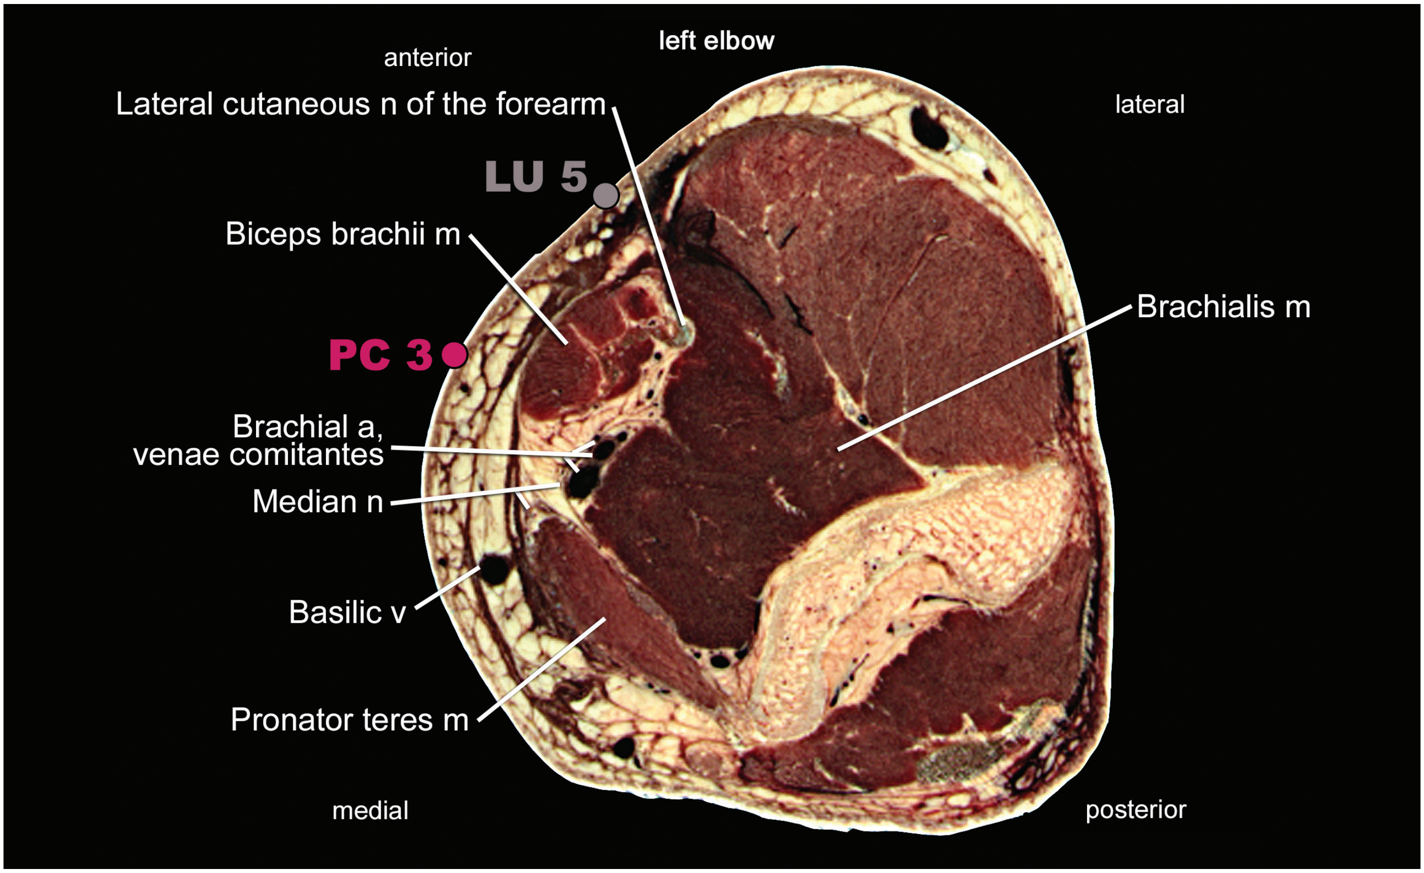

Figure 9-10. This cross-section at the level of PC 3 reveals the many myofascial and neurovascular structures one could influence with treatment at this site.

ulna. Between PC 3 and PC 4, a fibrous arcade associated with the middle finger's portion of the flexor digitorum superficialis overlies the nerve, potentially producing problems.

Vessels

- **Brachial artery:** A continuation of the axillary artery, the brachial artery supplies the main arterial supply to the arm. The brachial artery gives rise to the radial and ulnar arteries. Other main branches include the deep artery of the arm (profunda brachii artery) and the superior and inferior ulnar collateral arteries, which help form the elbow arterial anastomoses. The median nerve accompanies the brachial artery as it courses along the brachium.
- **Brachial vein:** The pair of brachial veins accompanies the brachial artery and frequently encompasses the artery, forming a common vascular sheath by means of their anastomotic interconnections.

Blood draining from the brachial vein is further pushed along its pathway by the brachial artery's pulsations. The brachial veins form as a result of the union of veins which travel with the radial and ulnar arteries. They drain into the axillary vein after joining with the basilic vein.

- **Basilic vein:** The basilic vein courses along the medial aspect of the arm and ultimately empties into the axillary vein after merging with the brachial veins. The basilic vein arises from the medial aspect of the dorsal venous network of the hand and ascends along the posteromedial forearm. At the elbow, it joins the median cubital vein.

Clinical Relevance: The arterial patterns of the thoracic limb vary widely. Lack of awareness of possible variations can complicate surgery with ischemia or hematoma. Unusual vascular patterns of the hand could pose problems following injection where local necrosis and ischemia could occur.[22]

Brachial artery entrapment by the lacertus fibrosus in the cubital fossa may impair arterial perfusion of the biceps tendon, increasing the risk of degeneration and rupture. Arterial entrapment syndrome (by the lacertus fibrosus) can result from arterial anomalies, thoracic limb hypertrophy, and lacertus fibrosus restriction.[23] Symptoms of brachial artery compression include cold intolerance as well as loss of both radial and ulnar pulses with pronation of the wrist and hand.

Indications and Potential Point Combinations

- **Chest pain:** PC 3, PC 6, CV 17.
- **Tremors in the arms and hands:** PC 3, HT 7, LI 4.
- **Elbow and hand pain:** Check for median nerve compression at the elbow from the lacertus fibrosus, an accessory lacertus fibrosus, a supracondylar process with the ligament of Struthers, pronator teres compression, chronic compartment syndrome, or partial rupture of the distal biceps insertion with the development of a hematoma or compressive bursa.[6]
- **Median neuropathy due to pronator teres syndrome:**[7] PC 3, PC 4. HT 3, local pronator teres muscle trigger points.
- **Medial epicondylitis:** PC 3, HT 3, local trigger points.

Evidence-Based Applications

- Acupuncture at LU 7, LI 4, LI 11, ST 40, PC 3, and PC 6 resulted in immediate improvement in forced expiratory volume in 1 second (FEV1) in **asthma patients.**[8]
- Electroacupuncture stimulation of PC 3 at 10 Hz for 15 minutes improved blood circulation at PC 4 by means of increasing nitric oxide (NO) release. Cyclic GMP was found to mediate the signaling functions of nitric oxide to improve **local microcirculation.** This study suggests that one of the mechanisms of action for how acupuncture works locally to improve or modulate blood flow involves increasing local tissue levels of NO.[9,24]

PC 4

Xi Men "Xi-Cleft Gate"

On the flexor aspect of the antebrachium, 5 cun proximal to the wrist crease (and PC 7) on a line adjoining PC 3 and PC 7. Along the ulnar side of the flexor carpi radialis tendon, or between the tendons of the flexor carpi radialis and the palmaris longus, when the latter is present.

Connective Tissues

- **Interosseous membrane between the radius and ulna:** Binds the two bones of the forearm. Allows load on the forearm to distribute between the radius and ulna. The interosseous membrane is a complex structure consisting of a central band, proximal interosseous band, membranous portions, and accessory bands. The central band inhabits the region of PC 4 and extends to PC 5. The central portion of the interosseous membrane exhibits the most strength, considered by some tantamount in strength to the anterior cruciate ligament or patellar tendon. The anterior interosseous vessels and nerve supply the PC (volar) surface of the membrane; the posterior interosseous counterparts supply the TH (dorsal) surface.

The interosseous membrane provides longitudinal stability to the forearm.[7] The forearm can be regarded as a joint with the interosseous membrane acting as the ligamentous connection.[8] The forearm complex, or joint, supports forearm function; rotation of the radius around the ulna is required for activities of daily living such as eating and maintaining personal hygiene.[9]

Clinical Relevance: High-force compressive trauma can injure the forearm and elbow, tearing the membrane, fracturing the radial head, and causing failure of the triangular fibrocartilage complex. Instability of the forearm leads to considerable pain and debility by limiting antebrachial motion and disturbing the biomechanics of the wrist.[10] One injury pattern that precipitates forearm instability involves axial load transmitted through the wrist to the elbow. The diagnosis is often overlooked; early recognition and effective care improve outcomes, as only a fifth of patients with delayed intervention experience satisfactory recovery.[11] Whether or not patients pursue surgery, restoring soft tissue stability remains a critical component in the treatment of chronic radioulnar dissociation injury. Nonsurgical means of improving tissue health and proprioception include acupuncture and related techniques. Laser therapy fosters tissue healing. Massage lessens myofascial restriction and improves proprioception and circulation, as does acupuncture.

Muscles and Tendons

- **Flexor digitorum superficialis muscle:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints.
- **Flexor digitorum profundus muscle:** Flexes the distal phalanges of the fingers at the distal interphalangeal joints.
- **Palmaris longus tendon:** Tightens the palmar aponeurosis and flexes the hand at the wrist. Not present in all individuals.
- **Flexor carpi radialis muscle:** Flexes and abducts the hand at the wrist.

Clinical Relevance: Trigger point pathology in the following muscles at or near PC 4 lead to their respective pain referral patterns:

- **Flexor digitorum superficialis and profundus:** Radial head of each muscle group refers pain to the palmar middle finger from PC 8 to PC 9.
- **Palmaris longus:** Pain from a palmaris longus trigger point just proximal to PC 4 sends pain along the PC channel to the palm between PC 8 and HT 8, where it centralizes.
- **Flexor carpi radialis:** Issues pain along the PC channel to the wrist, centered strongly over PC 7 and spilling toward LU 9. At times, extends to the palm near PC 8.

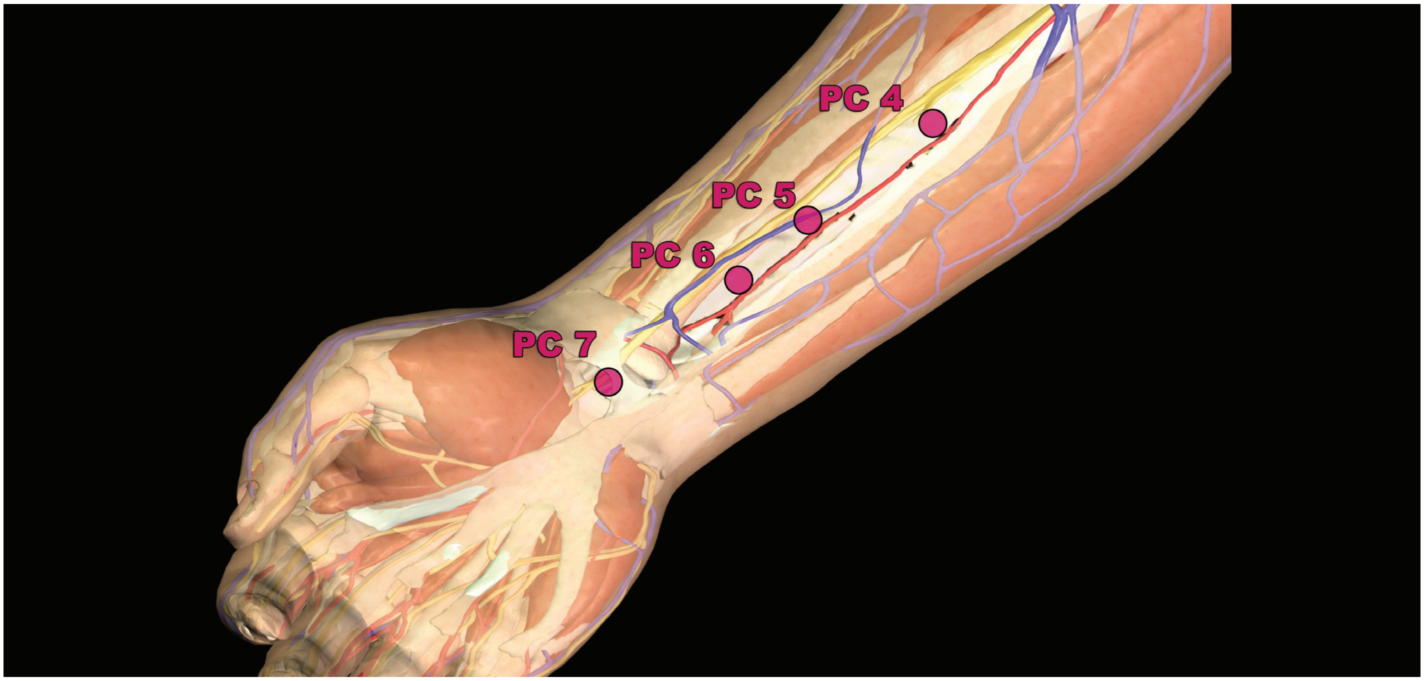

Figure 9-11. PC 4 through PC 7 line up neatly along the median nerve, as indicated here.

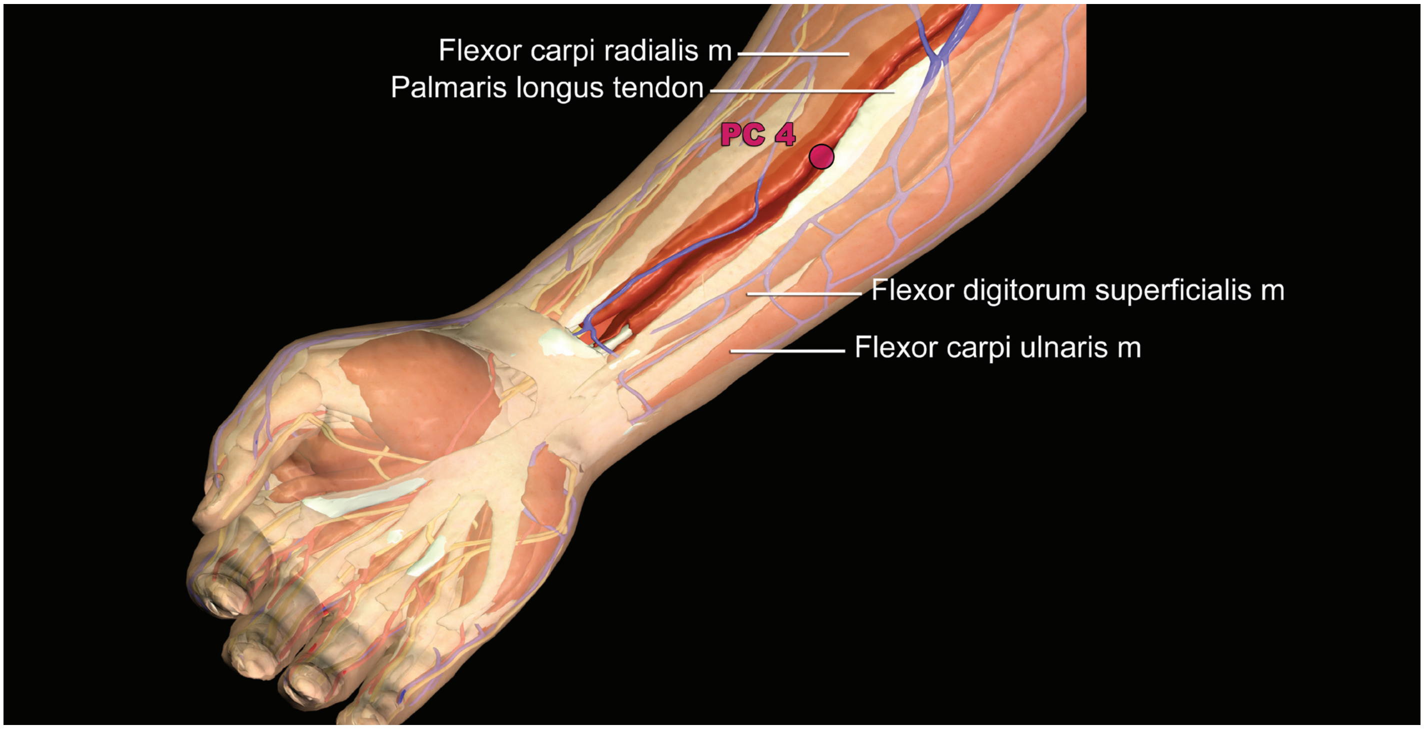
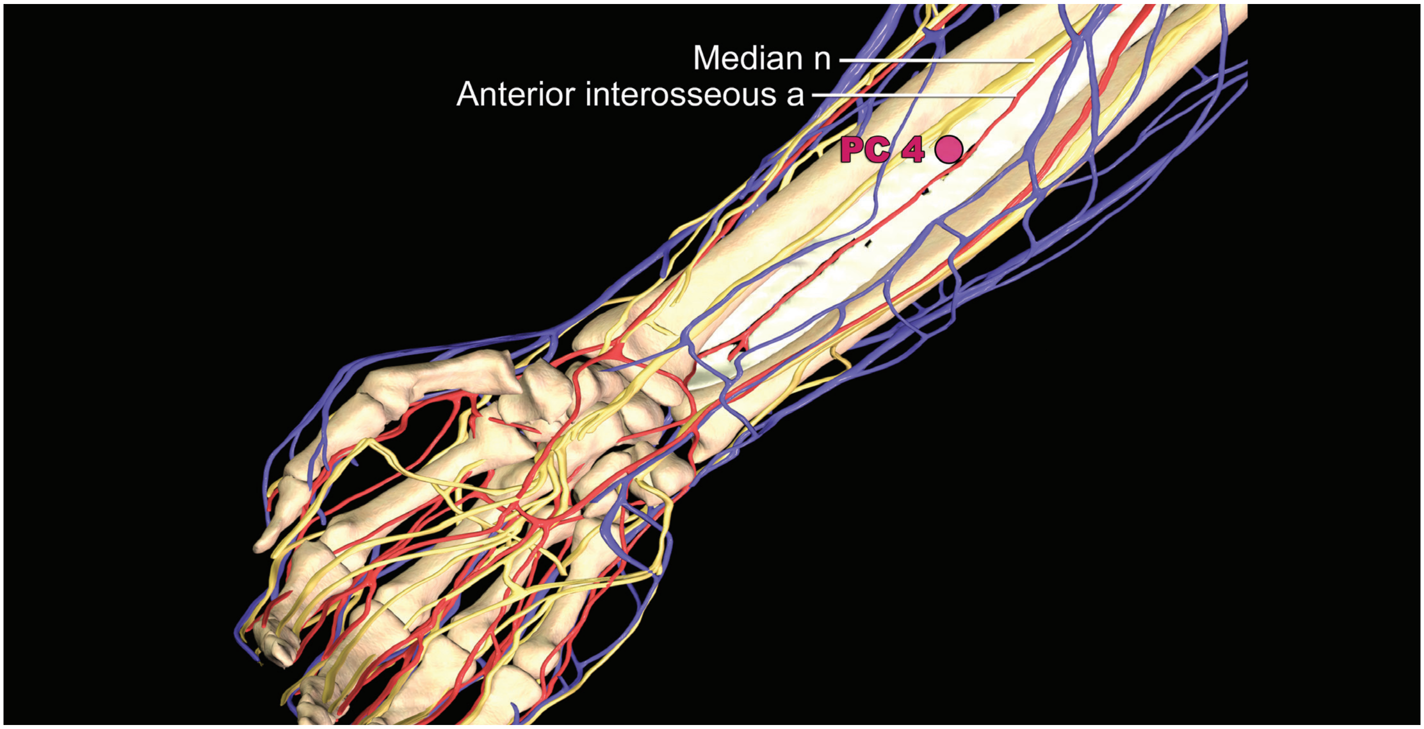


Flexor carpi radialis m
Palmaris longus tendon
PC 4
Flexor digitorum superficialis m
Flexor carpi ulnaris m

Figure 9-12. The descriptive term for PC 4, "Cleft Gate", refers to its role as a xi-cleft point according to Chinese medicine. Xi-cleft points are advocated for acute musculoskeletal trauma or pain along the channel. As shown here, PC 4 reflects the anatomical characteristic shared by other xi-cleft points of occurring at the myotendinous junction. Mechanosensitive receptors at or near the myotendinous junction not only regulate muscle function, but they also provoke reflexes that regulate cardiovascular responses during exercise.[19] Golgi tendon organs (GTO) heavily invest myotendinous locations; stimulation of these mechanoreceptors fosters an autogenic inhibition reflex via Ib afferent fibers acting on interneurons in the spinal cord. These interneurons regulate muscle activity by coordinating impulses from both the spinal cord and cerebellum that govern movement. Thus, acupuncture at xi-cleft points may neuromodulate muscle responses to stretch and contraction.[20]



Median n
Anterior interosseous a
PC 4

Figure 9-13. This image depicts the neurovasculature related to PC 4; i.e., the median nerve and and the anterior interosseous artery. The anterior interosseous nerve accompanies its companion vessels along the interosseous groove, although the nerve does not appear in this image.

In addition, a myofascial trigger point in the medial head of the triceps can cause pain to travel from the elbow at PC 3-HT 3 where it localizes strongly. The pain pattern then extends down the PC/HT line to the ring finger and pinky.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm. A branch of the ulnar nerve.
- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the radial volar aspect of the forearm, and a portion of the dorsal radial aspect of the distal forearm.
- **Median nerve (C6-T1):** The median nerve in the PC 4-PC 6 region is responsible for issuing the mechanosensitive signals to the brain that stimulate cardiopulmonary modulatory reflexes through the rostral ventrolateral medulla. In addition, muscular branches supply the pronator teres and pronator quadratus muscles and all of the forearm flexors (including the flexor carpi radialis, the palmaris longus, and the flexor digitorum superficialis muscles), except the flexor carpi ulnaris and medial half of the flexor digitorum profundus muscle. The median nerve then innervates all of the thenar muscles except for the adductor pollicis and deep head of the flexor pollicis brevis. Also supplies the lumbrical muscles for digits II and III, and provides sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (thumb, forefinger, and middle finger), along with the radial aspect of the ring finger, as well as the adjacent palmar areas. Four branches arise from the median nerve: the recurrent (thenar), lateral, medial, and palmar cutaneous. The recurrent branch supplies the abductor pollicis brevis, the opponens pollicis, and the superficial head of the flexor pollicis brevis.

The lateral branch supplies the 1st lumbrical, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.

- **Anterior interosseous nerve:** Arises from the median nerve.

Supplies the flexor digitorum profundus to the index and middle fingers, the flexor pollicis longus, and the pronator quadratus muscles. Also supplies the anterior surface of the interosseous membrane. The only motor nerve that innervates the deep muscles of the forearm. A pure motor nerve.

Clinical Relevance: Median nerve anatomy on the forearm varies eight ways.[12] As one example, the median nerve may divide in the proximal or middle third of the forearm and travel as a couple, split by a persistent median artery or muscle. It may then rejoin proximal to the transverse carpal ligament. Compression at any site of the median nerve, from root to destination, can cause abnormalities of sensation and function. “Double-crush” phenomenon refers to two sites of pressure producing problems for the nerve. As such, one should palpate the entire course of the nerve for evidence of entrapment.

Compression of the median nerve can be best understood by considering the course of the nerve as it travels from cubital fossa to wrist. First, the nerve passes between the two heads of the pronator teres muscle. It then courses deep to the fibrous arch formerly known as the “subliimis bridge”, created by the two heads of origin of the flexor digitorum superficialis muscle; these heads arise from the medial humeral epicondyle and the radius.[13]

The most common source of median nerve compression is carpal tunnel syndrome; that said, however, nerve dysfunction may arise from pressure elsewhere along its path. Space-occupying lesions in the carpal tunnel produce pain and paresthesias in the radial side of the palmar aspect of the hand. Problems typically worsen at night or following repetitive and forceful hand motion. Nonsurgical management of carpal tunnel syndrome and other median neuropathies should include acupuncture, massage, and/or laser therapy directed to both the source of compression and nearby sites. Proximal points can include PC 4.

Isolated anterior interosseous nerve compression may occur after repetitivemovement involving flexion of the elbow and/or pronation of theforearm.[1] Injury of the anterior interosseous nerve manifests as weakness in interphalangeal joint flexion or paresis of the distal interphalangeal joints of the index and middle fingers.[14] Compression of the anterior interosseous nerve occurs along the course of the PC channel and follows trauma, iatrogenic injury (dressings, slings, venipuncture), and elbow or shoulder arthroscopy. Anatomic sources of compression include: 1) the tendinous origin of the deep head of either the pronator teres or flexor digitorum superficialis to the middle finger; 2) a site of thrombosis of the ulnar collateral vessels crossing the anterior interosseous nerve; 3) accessory muscles or tendons of the flexor digitorum superficialis or the flexor pollicis longus (i.e., Gantzer’s muscle); 4) an aberrant radial artery; 5) tendinous portions of the palmaris longus or flexor carpi radialis brevis muscles, or 6) an enlarged bicipital bursa in the vicinity of PC 3.

Entrapment sites of the anterior interosseous and median nerves resemble one another because they pursue parallel trajectories. No matter which nerve becomes compressed, physical medicine can improve the symptoms by releasing the dysfunction at the heart of the entrapment.

Median nerve stimulation itself may prove therapeutic for a number of conditions. First and foremost, neuromodulation of the median nerve facilitates its recovery from the problems described above, wherein chronic pressure compromises nerve health. In addition, median nerve stimulation affords an array of homeostatic effects based on its neuromodulation of rostral ventrolateral medulla (RVLM) function. The RVLM affects cardiopulmonary physiology; neuromodulation through physical medicine modalities modulates cardiovascular excitatory responses.[15] Acupuncture points along the median nerve regulate blood pressure and protect against hypotension.

Median nerve stimulation also treats causalgia, otherwise known as complex regional pain syndrome type II (CRPS II).[16] It also reduces neuropathic pain in cases of median nerve damage following carpal tunnel surgery.[17]

Chronic regional pain disorders typically exhibit autonomic features such as vasomotor or sudomotor dysfunction. CRPS type I (reflex sympathetic dystrophy) produces: skin color changes, edema, abnormal sweating (sudomotor activity),

Figure 9-14. The density of muscle and tendon tissue deep to PC 4 illustrates the point's applicability in cases of myofascial restriction of the palmar, or volar, surface of the antebrachium. Note, too, the position of the median nerve between the flexor digitorum superficialis and flexor digitorum profundus muscles. Consider how forceful and sustained flexion of the digits could compress the nerve.

regional pain, dysesthesia, temperature changes, and a history of trauma or a noxious event. CRPS type II adds a peripheral nerve lesion such as neuroma. Peripheral nerve stimulation provided by acupuncture and related techniques should precede implanted nerve stimulators or spinal cord stimulation, in that the non-invasive neuromodulation affords a safer and more comfortable method of fostering nerve repair and analgesia.

Vessels

- **Anterior interosseous artery and vein:** The larger partners of the posterior interosseous vessels, the anterior osseous vessels supply and drain the interosseous membrane and deep myofascia. Both vessels issue perforators to each other through the membrane; segmental vessels supply the periosteum of the radius and ulna.[18]
- **Median artery:** A branch of the anterior or common interosseous artery, the median artery arises from the proximal part of the interosseous artery and supplies the median nerve throughout its course along the forearm. In some individuals, the median arterial branch is sizeable and continues into the hand to join in the formation of the superficial palmar arch. When present, the median artery adds to the already crowded carpal canal and may cause compression of the median nerve, leading to carpal tunnel syndrome.
- **Median antebrachial vein:** Sometimes absent, the median antebrachial vein begins at the base of the dorsum of the thumb. It makes its way around the radial aspect of the wrist and moves proximally in the middle of the anterior aspect of the forearm. Its course runs between the cephalic and basilic veins. It occasionally divides into intermediate median cephalic and basilic veins, which drain into their respective veins. The median cubital vein often receives this median vein of the forearm, otherwise known as the median antebrachial vein.

Clinical Relevance: Extraneous fibrous bands and variant muscles occur with notable frequency in the antebrachium. Their oblique courses cross both nerves and vessels. Gantzer's muscle is also a well-known culprit inciting neurovascular compression, as noted above.

Indications and Potential Point Combinations

- **Acute disorders of cardiac and circulatory systems such as angina pectoris, chest pain, tachycardia:** PC 5, PC 6, HT 3, ST 36.
- **Anterior interosseous nerve syndrome, exhibited by inability to make the "OK" sign with the thumb firmly opposing the tip of the index finger**. The nerve impingement generated by compression at the fibrous arch of the flexor digitorum superficialis and pronator teres can affect flexion at the interphalangeal joint of the thumb (because of weakness in the flexor pollicis longus muscle) as well as flexion of the distal interphalangeal joint of the index finger (because the anterior interosseous nerve supplies the radial half of the flexor digitorum profundus):[2] PC 4, PC 5, trigger points in the flexor digitorum superficialis and pronator teres muscles. LU 6, PC 6, PC 7 to stimulate return of motor function in afflicted muscles.

Evidence-Based Applications

- Benefits patients with **coronary insufficiency.**[3]
- Electroacupuncture at PC 4 and PC 6 regulates blood pressure in cases of **hypotension.**[4]
- Acupuncture on PC 4 decreased **heart rate** by increasing cardiac vagal activity and decreasing cardiac sympathetic activity.[5]
- Electroacupuncture stimulation of PC 3 at 10 Hz for 15 minutes improved blood circulation at PC 4 by means of increasing nitric oxide release. Cyclic GMP was found to mediate the signaling functions of nitric oxide to improve **local microcirculation.**[6]

PC 5
Jian Shi "Intermediate Messenger", "Intermediary Courier", "Minister Space"

On the flexor surface of the distal antebrachium, 3 cun proximal to the wrist crease (and PC 7), on the ulnar aspect of the flexor carpi radialis tendon, or between the tendons of the flexor carpi radialis and palmaris longus (when the latter is present). The point occurs one quarter of the distance from the wrist to the elbow.

Connective Tissues

- **Interosseous membrane between the radius and ulna:** Binds the two bones of the forearm. Allows load on the forearm to distribute between the radius and ulna. The interosseous membrane is a complex structure consisting of a central band, proximal interosseous band, membranous portions, and accessory bands. The central band spans the region of PC 4 and PC 5. The central portion of the interosseous membrane possesses the most strength, considered by some tantamount in strength to the anterior cruciate ligament or patellar tendon. The anterior interosseous vessels and nerve supply the PC (volar) surface of the membrane; the posterior interosseous counterparts supply the TH (dorsal) surface.

The interosseous membrane provides longitudinal stability to the forearm.[2] The forearm acts as a joint with the interosseous membrane serving as the ligamentous connection.[3] The forearm complex, or joint, supports forearm function; rotation of the radius around the ulna is required for activities of daily living such as eating and maintaining personal hygiene.[4]

Clinical Relevance: High-force compressive trauma can injure the forearm and elbow, tearing the membrane, fracturing the radial head, and causing failure of the triangular fibrocartilage complex. Instability of the forearm leads to considerable pain and debility by limiting antebrachial motion and disturbing the biomechanics of the wrist.[5] One injury pattern that precipitates forearm instability involves axial load transmitted through the wrist to the elbow. The diagnosis is often overlooked; early recognition and effective care improve outcomes, as only a fifth of patients with delayed intervention experience satisfactory recovery.[6] Whether or not patients pursue surgery, restoring soft tissue stability remains a critical component in the treatment of chronic radioulnar dissociation injury. Nonsurgical means of improving tissue health and proprioception include acupuncture and related techniques. Laser therapy fosters tissue healing. Massage lessens myofascial restriction and improves proprioception and circulation, as does acupuncture.

Muscles and Tendons

- **Flexor digitorum superficialis muscle:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints.
- **Flexor digitorum profundus muscle:** Flexes the distal phalanges of the fingers at the distal interphalangeal joints.
- **Palmaris longus tendon:** Tightens the palmar aponeurosis and flexes the hand at the wrist.
- **Flexor carpi radialis muscle and tendon:** Flexes and abducts the hand at the wrist.
- **Pronator quadratus muscle:** Pronates the antebrachium, binds the radius and ulna.

Clinical Relevance: Trigger point pathology in the following muscles at or near PC 5 lead to their respective pain referral patterns:

  - **Flexor digitorum superficialis and profundus:** Radial head of each muscle group refers pain to the palmar middle finger from PC 8 to PC 9.
  - **Palmaris longus:** Pain from a palmaris longus trigger point just proximal to PC 4 sends pain along the PC channel to the palm between PC 8 and HT 8, where it centralizes.
  - **Flexor carpi radialis:** Issues pain along the PC channel to the wrist, centered strongly over PC 7 and spilling toward LU 9. At times, extends to the palm near PC 8.

In addition, a myofascial trigger point in the medial head of the triceps can cause pain to travel from the elbow at PC 3-HT 3 where it localizes strongly. The pain pattern then extends down the PC/HT line to the ring finger and pinky.

Excessive tension in the pronator quadratus muscle predisposes a patient to entrapment of the anterior interosseous nerve, as indicated in Figure 9-16.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm. A branch of the ulnar nerve.
- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the radial volar aspect of the forearm, and a portion of the dorsal radial aspect of the distal forearm.

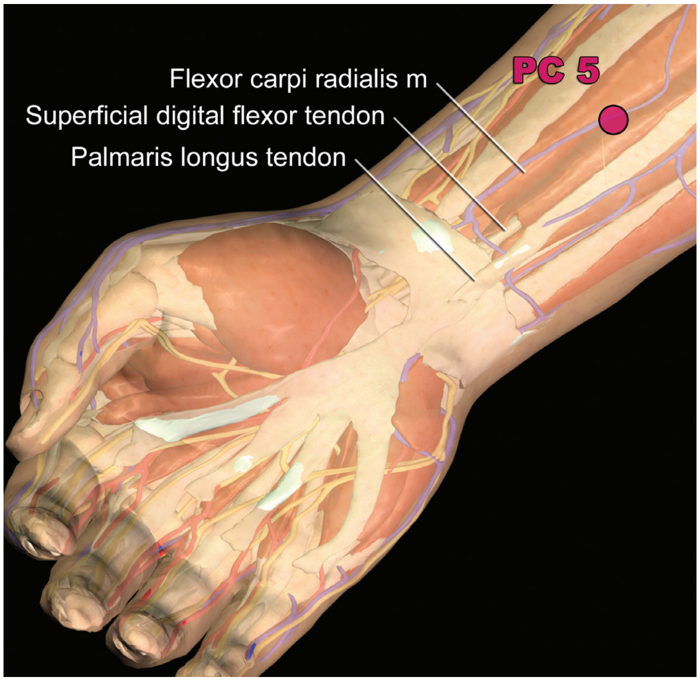

Figure 9-15. As the "messenger in the space between two sinews", the name "Intermediary Courier" for PC 5 refers to the point's location along the groove between the flexor carpi radialis muscle and the palmaris longus tendon.

- **Median nerve (C6-T1):** The median nerve in the PC 5-PC 6 region is responsible for issuing the mechanosensitive signals to the brain that stimulate cardiopulmonary modulatory reflexes through the rostral ventrolateral medulla. In addition, muscular branches supply the pronator teres and pronator quadratus muscles and all of the forearm flexors (including the flexor carpi radialis, the palmaris longus, and the flexor digitorum superficialis muscles), except the flexor carpi ulnaris and medial half of the flexor digitorum profundus muscle. The median nerve then innervates all of the thenar muscles except for the adductor pollicis and deep head of the flexor pollicis brevis. Also supplies the lumbrical muscles for digits II and III, and provides sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (thumb, forefinger, and middle finger), along with the radial aspect of the ring finger, as well as the adjacent palmar areas. Four branches arise from the median nerve: the recurrent (thenar), lateral, medial, and palmar cutaneous. The recurrent branch supplies the abductor pollicis brevis, the opponens pollicis, and the superficial head of the flexor pollicis brevis. The lateral branch supplies the 1st lumbrical, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.
- **Anterior interosseous nerve:** Arises from the median nerve, a purely motor nerve that innervates the deep antebrachial muscles. Supplies the flexor digitorum profundus to the index and middle fingers, the flexor pollicis longus, and the pronator quadratus muscles. Also supplies the anterior surface of the interosseous membrane.

Clinical Relevance: Median nerve anatomy on the forearm varies eight ways.[7] As one example, the median nerve may divide in the proximal or middle third of the forearm and travel as a couple, split by a persistent median artery or muscle. It may then rejoin proximal to the transverse carpal ligament. Compression at any site of the median nerve, from root to destination, can cause abnormalities of sensation and function. “Double-crush” phenomenon refers to two sites of pressure producing problems for the nerve. As such, one should palpate the entire course of the nerve for evidence of entrapment.

Compression of the median nerve can be best understood by considering the course of the nerve as it travels from cubital fossa to wrist. First, the nerve passes between the two heads of the pronator teres muscle. It then courses deep to the fibrous arch formerly known as the “subliimis bridge”, created by the two heads of origin of the flexor digitorum superficialis muscle; these heads arise from the medial humeral epicondyle and the radius.[8]

The most common source of median nerve compression is carpal tunnel syndrome; that said, however, nerve dysfunction may arise from pressure elsewhere along its path. Space-occupying lesions in the carpal tunnel produce pain and paresthesias in the radial side of the palmar aspect of the hand. Problems typically worsen at night or following repetitive and forceful hand motion. Nonsurgical management of carpal tunnel syndrome and other median neuropathies should include acupuncture, massage, and/or laser therapy directed to both the source of compression and nearby sites. Proximal points can include PC 5.

Isolated anterior interosseous nerve compression may occur after repetitive movement involving flexion of the elbow and/or pronation of the forearm.[1] Injury of the anterior interosseous nerve manifests as weakness in interphalangeal joint flexion or paresis of the distal interphalangeal joints of the index and middle fingers.[9] Pain arises in the volar antebrachium; people with isolated anterior interosseous neuropathy cannot make the “ok” sign with the thumb and forefinger, making a pinching movement with these digits. Handwriting also becomes difficult.[10]

Compression of the anterior interosseous nerve occurs along the course of the PC channel and follows trauma, iatrogenic injury (dressings, slings, venipuncture), and elbow or shoulder arthroscopy. Anatomic sources of compression include: 1) the tendinous origin of the deep head of either the pronator teres or flexor digitorum superficialis to the middle finger; 2) a site of thrombosis of the ulnar collateral vessels crossing the anterior interosseous nerve; 3) accessory muscles or tendons of the flexor digitorum superficialis or the flexor pollicis longus (i.e., Gantzer’s muscle); 4) an aberrant radial artery; 5) tendinous portions of the palmaris longus or flexor carpi radialis brevis muscles, or 6) an enlarged bicipital bursa in the vicinity of PC 3.

Entrapment sites of the anterior interosseous and median nerves resemble one another because they pursue parallel trajectories. No matter which nerve becomes compressed, physical medicine can improve the symptoms by releasing the dysfunction at the heart of the entrapment.

Median nerve stimulation itself may prove therapeutic for a number of conditions. First and foremost, neuromodulation of the median nerve facilitates its recovery from the problems described above, wherein chronic pressure compromises nerve health. In addition, median nerve stimulation affords an array of homeostatic effects based on its neuromodulation of rostral ventrolateral medulla (RVLM) function. The RVLM affects cardiopulmonary physiology; neuromodulation through physical medicine modalities modulates cardiovascular excitatory responses.[11] Acupuncture points along the median nerve regulate blood pressure and protect against hypotension. Stimulation of PC 5 and PC 6 also alters cardiovascular function by acting on the cholinergic neurons in the nucleus ambiguus, likely by means of enkephalinergic pathways.[12]

This link between the median nerve, the RVLM, and the indications of PC 6 that pertain to cardiac activity has been highlighted by a study evaluating the predictive value of median nerve somatosensory evoked potentials for nonawakening from coma.[13] That is, adults who suffered hypoxic-ischemic encephalopathy and progressed to coma demonstrated absent somatosensory evoked potential responses from the median nerve. In other words, stimulation of the median nerve was unable to arouse the brain, likely due to the damage in the brainstem at the cardiopulmonary centers in the RVLM.

Median nerve stimulation also treats causalgia, otherwise known as complex regional pain syndrome type II (CRPS II).[14] It also reduces neuropathic pain in cases of median nerve damage following carpal tunnel surgery.[15]

Chronic regional pain disorders typically exhibit autonomic features such as vasomotor or sudomotor dysfunction. CRPS type I (reflex sympathetic dystrophy) produces: skin color changes, edema, abnormal sweating (sudomotor activity),

regional pain, dysesthesia, temperature changes, and a history of trauma or a noxious event. CRPS type II adds a peripheral nerve lesion such as neuroma. Peripheral nerve stimulation provided by acupuncture and related techniques should precede implanted nerve stimulators or spinal cord stimulation, in that the non-invasive neuromodulation affords a safer and more comfortable method of fostering nerve repair and analgesia.

Vessels

- **Anterior interosseous artery and vein:** The larger partners of the posterior interosseous vessels, the anterior osseous vessels supply and drain the interosseous membrane and deep myofascia. Both vessels issue perforators to each other through the membrane; segmental vessels supply the periosteum of the radius and ulna. The anterior interosseous artery supplies both sides of the interosseous membrane by providing a dorsal branch that courses along the distal posterior portion of the interosseous membrane.
- **Median artery:** A branch of the anterior or common interosseous artery, the median artery arises from the proximal part of the interosseous artery and supplies the median nerve throughout its course along the forearm. In some individuals, the median arterial branch is sizeable and continues into the hand to join in the formation of the superficial palmar arch. When present, the median artery adds to the already crowded carpal canal and may cause compression of the median nerve, leading to carpal tunnel syndrome.
- **Median antebrachial vein:** Sometimes absent, the median antebrachial vein begins at the base of the dorsum of the thumb. It makes its way around the radial aspect of the wrist and moves proximally in the middle of the anterior aspect of the forearm. Its course runs between the cephalic and basilic veins. It occasionally divides into intermediate median cephalic and basilic veins, which drain into their respective veins. The median cubital vein often receives this median vein of the forearm, otherwise known as the median antebrachial vein.

Clinical Relevance: Extraneous fibrous bands and variant muscles occur with notable frequency in the antebrachium. Their oblique courses cross both nerves and vessels. Gantzer's muscle is also a well-known culprit inciting neurovascular compression, as noted above.

Indications and Potential Point Combinations

- **Acute disorders of cardiac and circulatory systems: angina pectoris, chest pain, tachycardia:** PC 5, PC 6, HT 3, ST 36, LR 3.
- **Pain in the arm, forearm, or middle finger:** The palmaris longus muscle trigger points radiate toward the palm (and PC 8). PC 5, PC 4, PC 6, and PC 7 all line up along the referred pain route. The flexor carpi radialis trigger point sends referred pain to the wrist in the vicinity of PC 7. PC 5, PC 6, and PC 7 plus local trigger points are indicated here. A trigger point in the radial head of the flexor digitorum superficialis muscle issues pain to the palmar aspect of the middle finger. For this pain pattern, needle PC 5, local trigger points, and web space (Baxie) points on either side of the middle digit.

Evidence-Based Applications

- Transcutaneous electrical nerve stimulation (TENS) applied to PC 5 and PC 6 **reduced the severity and incidence of hypotension** after spinal anesthesia in parturients undergoing Cesarean section.[1]
- Electroacupuncture from PC 5 to PC 6 **reduced the severity of hypotension** during anesthesia in patients undergoing liver transplantation, with no significant differences observed between the electroacupuncture group and those receiving norepinephrine as a vasoconstrictor.[17]
- Electroacupuncture at certain points such as PC 5 or PC 6 or LU 7 and LI 4, in addition to several others, may **improve exercise performance and post-exercise recovery.**[18]

PC 6

Nei Guan "Inner Pass"

On the distal volar antebrachium, 2 cun proximal to the wrist crease (and PC 7), on the ulnar side of the flexor carpi radialis tendon, or between the tendons of the flexor carpi radialis and palmaris longus (when the latter is present).

Caution: The median nerve underlies this point. Needling the nerve will generate an electrical sensation. Do not traumatize the nerve through excessive stimulation.

Connective Tissues

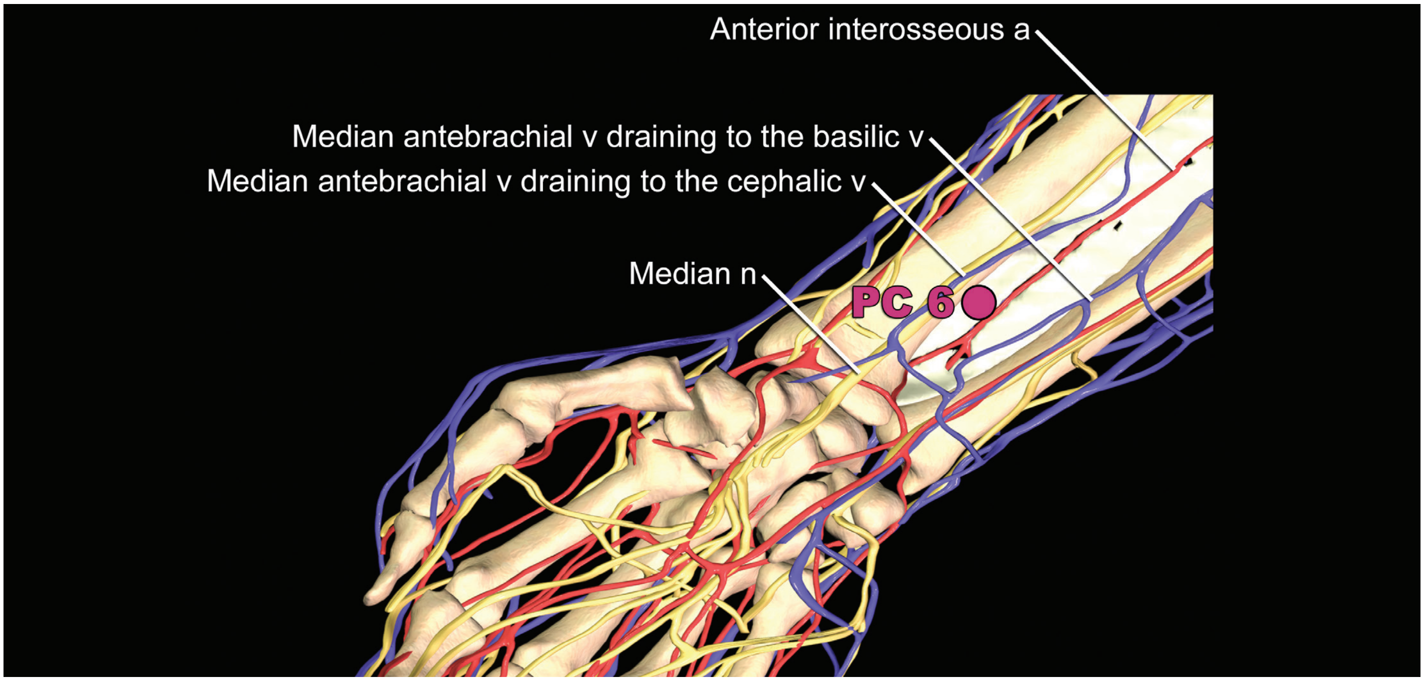
- **Interosseous membrane between the radius and ulna:** Binds the two bones of the forearm. Allows load on the forearm to distribute between the radius and ulna. The interosseous membrane is a complex structure consisting of a central band, proximal interosseous band, membranous portions, and accessory bands. The central band spans the region of PC 4 and PC 5. The central portion of the interosseous membrane possesses the most strength, considered by some tantamount in strength to the anterior cruciate ligament or patellar tendon. The anterior interosseous vessels and nerve supply the PC (volar) surface of the membrane; the posterior interosseous counterparts supply the TH (dorsal) surface.

The interosseous membrane provides longitudinal stability to the forearm.[54] The forearm acts as a joint with the interosseous membrane serving as the ligamentous connection.[55] The forearm complex, or joint, supports forearm function; rotation of the radius around the ulna is required for activities of daily living such as eating and maintaining personal hygiene.[56]

Clinical Relevance: High-force compressive trauma can injure the forearm and elbow, tearing the membrane, fracturing the radial head, and causing failure of the triangular fibrocartilage complex. Instability of the forearm leads to considerable pain and debility by limiting antebrachial motion and disturbing the biomechanics of the wrist.[57] One injury pattern that precipitates forearm instability involves axial load transmitted through the wrist to the elbow. The diagnosis is often overlooked; early recognition and effective care improve outcomes, as only a fifth of patients with delayed intervention experience satisfactory recovery.[58] Whether or not patients pursue surgery, restoring soft tissue stability remains a critical component in the treatment of chronic radioulnar dissociation injury. Nonsurgical means of improving tissue health and proprioception include acupuncture and related techniques. Laser therapy fosters tissue healing. Massage lessens myofascial restriction and improves proprioception and circulation, as does acupuncture.

Muscles and Tendons

- **Flexor digitorum superficialis muscle:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints.
- **Flexor digitorum profundus muscle:** Flexes the distal phalanges of the fingers at the distal interphalangeal joints.
- **Palmaris longus tendon:** Tightens the palmar aponeurosis and flexes the hand at the wrist.



Anterior interosseous a

Median antebrachial v draining to the cephalic v
Median n
PC 6

Figure 9-17. The name "Inner Pass" refers to the connection, or passage, through the interosseous membrane of the anterior interosseous vessels that then supply the dorsal, as well as the volar surfaces of the distal antebrachium. The penetration of the membrane by the anterior interosseous artery is evident in this image just distal to PC 6, where the dorsal branch disappears through the connective tissue. This fact reinforces the neurovascular basis of the acupuncture channels in that PC 6 serves as the "luo connecting point" between the PC and Triple Heater (TH) channels, evidenced by a vascular conduit bridging the two. Here, TH 5 sits atop PC 6, but on the dorsal surface. This link between the median nerve, the RVLM, and the indications of PC 6 that pertain to cardiac activity has been highlighted by a study evaluating the predictive value of median nerve somatosensory evoked potentials for nonawakening from coma.[79] That is, adults who suffered hypoxic-ischemic encephalopathy and progressed to coma demonstrated absent somatosensory evoked potential responses from the median nerve. In other words, stimulation of the median nerve was unable to arouse the brain, likely due to the damage in the brainstem at the cardiopulmonary centers in the RVLM.

- **Flexor carpi radialis muscle and tendon:** Flexes and abducts the hand at the wrist.
- **Pronator quadratus muscle:** Pronates the antebrachium, binds the radius and ulna.

Clinical Relevance: Trigger point pathology in the following muscles at or near PC 5 lead to their respective pain referral patterns:

- **Flexor digitorum superficialis and profundus:** Radial head of each muscle group refers pain to the palmar middle finger from PC 8 to PC 9.
- **Palmaris longus:** Pain from a palmaris longus trigger point just proximal to PC 4 sends pain along the PC channel to the palm between PC 8 and HT 8, where it centralizes.
- **Flexor carpi radialis:** Issues pain along the PC channel to the wrist, centered strongly over PC 7 and spilling toward LU 9. At times, extends to the palm near PC 8.

In addition, a myofascial trigger point in the medial head of the triceps can cause pain to travel from the elbow at PC 3-HT 3 where it localizes strongly. The pain pattern then extends down the PC/HT line to the ring finger and pinky.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm. A branch of the ulnar nerve.
- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the radial volar aspect of the forearm, and a portion of the dorsal radial aspect of the distal forearm.
- **Median nerve (C6-T1):** The median nerve in the PC 5-PC 6 region is responsible for issuing the mechanosensitive signals to the brain that stimulate cardiopulmonary modulatory reflexes through the rostral ventrolateral medulla. In addition, muscular branches supply the pronator teres and pronator quadratus muscles and all of the forearm flexors (including the flexor carpi radialis, the palmaris longus, and the flexor digitorum superficialis muscles), except the flexor carpi ulnaris and medial half of the flexor digitorum profundus muscle. The median nerve then innervates all of the thenar muscles except for the adductor pollicis and deep head of the flexor pollicis brevis. Also supplies the lumbrical muscles for digits II and III, and provides sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (thumb, forefinger, and middle finger), along with the radial aspect of the ring finger, as well as the adjacent palmar areas. Four branches arise from the median nerve: the recurrent (thenar), lateral, medial, and palmar cutaneous. The recurrent branch supplies the abductor pollicis brevis, the opponens pollicis, and the superficial head of the flexor pollicis brevis.

The lateral branch supplies the 1st lumbrical, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.

- **Anterior interosseous nerve:** Arises from the median nerve, a purely motor nerve that innervates the deep antebrachial muscles. Supplies the flexor digitorum profundus to the index and middle fingers, the flexor pollicis longus, and the pronator quadratus muscles. Also supplies the anterior surface of the interosseous membrane.

Clinical Relevance: Median nerve anatomy on the forearm varies eight ways.[59] As one example, the median nerve may divide in the proximal or middle third of the forearm and travel as a couple, split by a persistent median artery or muscle. It may then rejoin proximal to the transverse carpal ligament. Compression at any site of the median nerve, from root to destination, can cause abnormalities of sensation and function. “Double-crush” phenomenon refers to two sites of pressure producing problems for the nerve. As such, one should palpate the entire course of the nerve for evidence of entrapment.

Compression of the median nerve can be best understood by considering the course of the nerve as it travels from cubital fossa to wrist. First, the nerve passes between the two heads of the pronator teres muscle. It then courses deep to the fibrous arch formerly known as the “subliimis bridge”, created by the two heads of origin of the flexor digitorum superficialis muscle; these heads arise from the medial humeral epicondyle and the radius.[60]

The most common source of median nerve compression is carpal tunnel syndrome; that said, however, nerve dysfunction may arise from pressure elsewhere along its path. Space-occupying lesions in the carpal tunnel produce pain and paresthesias in the radial side of the palmar aspect of the hand. Problems typically worsen at night or following repetitive and forceful hand motion. Nonsurgical management of carpal tunnel syndrome and other median neuropathies should include acupuncture, massage, and/or laser therapy directed to both the source of compression and nearby sites. Proximal points can include PC 6.

Isolated anterior interosseous nerve compression may occur after repetitive movement involving flexion of the elbow and/or pronation of the forearm.[1] Injury of the anterior interosseous nerve manifests as weakness in interphalangeal joint flexion or paresis of the distal interphalangeal joints of the index and middle fingers.[61] Pain arises in the volar antebrachium; people with isolated anterior interosseous neuropathy cannot make the “ok” sign with the thumb and forefinger, making a pinching movement with these digits. Handwriting also becomes difficult.[62]

Compression of the anterior interosseous nerve occurs along the course of the PC channel and follows trauma, iatrogenic injury (dressings, slings, venipuncture), and elbow or shoulder arthroscopy. Anatomic sources of compression include: 1) the tendinous origin of the deep head of either the pronator teres or flexor digitorum superficialis to the middle finger; 2) a site of thrombosis of the ulnar collateral vessels crossing the anterior interosseous nerve; 3) accessory muscles or tendons of the flexor digitorum superficialis or the flexor pollicis longus (i.e., Gantzer’s muscle); 4) an aberrant radial artery; 5) tendinous portions of the palmaris longus or flexor carpi radialis brevis muscles, or 6) an enlarged bicipital bursa in the vicinity of PC 3.

Entrapment sites of the anterior interosseous and median nerves resemble one another because they pursue parallel trajectories. No matter which nerve becomes compressed, physical medicine can improve the symptoms by releasing the dysfunction at the heart of the entrapment.

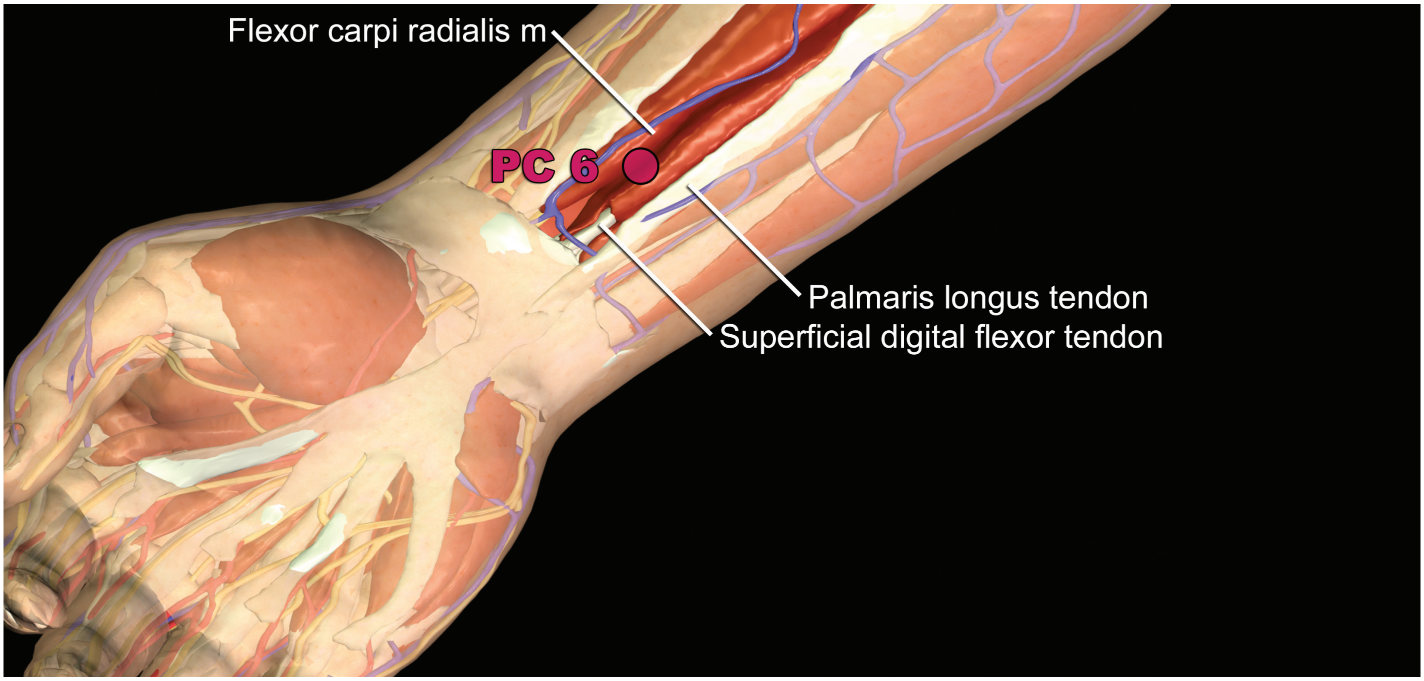

Figure 9-18. If the patient lacks a palmaris longus muscle, the radial aspect of the superficial digital flexor muscle serves as the ulnar border for the groove in which PC 6 sits. The flexor carpi radialis muscle continues to provide the radial border, as it has for PC 4 and PC 5.

Median nerve stimulation itself may prove therapeutic for a number of conditions. First and foremost, neuromodulation of the median nerve facilitates its recovery from the problems described above, wherein chronic pressure compromises nerve health. In addition, median nerve stimulation affords an array of homeostatic effects based on its neuromodulation of rostral ventrolateral medulla (RVLM) function. The RVLM affects cardiopulmonary physiology; neuromodulation through physical medicine modalities modulates cardiovascular excitatory responses.[63] Acupuncture points along the median nerve regulate blood pressure and protect against hypotension. Stimulation of PC 5 and PC 6 also alters cardiovascular function by acting on the cholinergic neurons in the nucleus ambiguus, likely by means of enkephalinergic pathways.[64]

Median nerve stimulation also treats causalgia, otherwise known as complex regional pain syndrome type II (CRPS II).[65] It also reduces neuropathic pain in cases of median nerve damage following carpal tunnel surgery.[66]

Chronic regional pain disorders typically exhibit autonomic features such as vasomotor or sudomotor dysfunction. CRPS type I (reflex sympathetic dystrophy) produces: skin color changes, edema, abnormal sweating (sudomotor activity), regional pain, dysesthesia, temperature changes, and a history of trauma or a noxious event. CRPS type II adds a peripheral nerve lesion such as neuroma. Peripheral nerve stimulation provided by acupuncture and related techniques should precede implanted nerve stimulators or spinal cord stimulation, in that the non-invasive neuromodulation affords a safer and more comfortable method of fostering nerve repair and analgesia.

Vessels

- **Anterior interosseous artery and vein:** The larger partners of the posterior interosseous vessels, the anterior osseous vessels supply and drain the interosseous membrane and deep myofascia. Both vessels issue perforators to each other through the membrane; segmental vessels supply the periosteum of the radius and ulna. The anterior interosseous artery supplies both sides of the interosseous membrane by providing a dorsal branch that courses along the distal posterior portion of the interosseous membrane.
- **Median artery:** A branch of the anterior or common interosseous artery, the median artery arises from the proximal part of the interosseous artery and supplies the median nerve throughout its course along the forearm. In some individuals, the median arterial branch is sizeable and continues into the hand to join in the formation of the superficial palmar arch. When present, the median artery adds to the already crowded carpal canal and may cause compression of the median nerve, leading to carpal tunnel syndrome.
- **Median antebrachial vein:** Sometimes absent, the median antebrachial vein begins at the base of the dorsum of the thumb. It makes its way around the radial aspect of the wrist and moves proximally in the middle of the anterior aspect of the forearm. Its course runs between the cephalic and basilic veins. It occasionally divides into intermediate median cephalic and basilic veins, which drain into their respective veins. The median cubital vein often receives this median vein of the forearm, otherwise known as the median antebrachial vein.

Clinical Relevance: Extraneous fibrous bands and variant muscles occur with notable frequency in the antebrachium. Their oblique courses cross both nerves and vessels. Gantzer's muscle is also a well-known culprit inciting neurovascular compression, as noted above.

Indications and Potential Point Combinations

- **Disorders of upper abdomen:** gastric and duodenal ulcers, nausea, vomiting: PC 6, ST 36, CV 12.
- **Emotional problems:** PC 6, SP 4, ST 36, GV 20.
- **Acupuncture analgesia for chest and upper abdominal surgery:** PC 6.
- **Carpal tunnel syndrome:** PC 6, PC 7, local trigger points. Also, target C5-C6 ventral cervical spinal nerve segments and facet joint points along with ST 36 to address central sensitization.[1]
- **Acute disorders of cardiac and circulatory systems such as angina pectoris, chest pain, arrhythmias, or tachycardia:** PC 5, PC 6, HT 3, ST 36, LR 3.
- **Pain in the arm, forearm, or middle finger:** The palmaris longus muscle trigger points radiate toward the palm (and PC 8). PC 6, PC 4, PC 5, and PC 7 all line up along the referred pain route. The flexor carpi radialis trigger point sends referred pain to the wrist in the vicinity of PC 7. PC 6, PC 5, and PC 7 plus local trigger points are indicated here. A trigger point in the radial head of the flexor digitorum superficialis muscle issues pain to the palmar aspect of the middle finger. For this pain pattern, needle PC 6, PC 5, local trigger points, and web space (Baxie) points on either side of the middle digit.
- **Nausea, vomiting:** PC 6, ST 36.

Evidence-Based Applications

- Acupuncture for carpal tunnel syndrome including PC 6 as one of the points was shown to be as effective as short-term low-dose prednisolone for mild-to-moderate **carpal tunnel syndrome.**[2]
- Acupuncture applied to PC 6 and PC 7 significantly improved nerve conduction velocity and symptoms in patients with **carpal tunnel syndrome.**[68]
- Prevents **postoperative nausea and vomiting** (double-blind RCT).[3]
- Acupressure at PC 6 has **anti-gagging effects in dental patients.**[4]
- Laser stimulation at PC 6 and CV 24 were each effective in controlling the **gagging reflex** in orthodontic patients.[69]
- Continuous, 24-hour acupressure on PC 6 as an adjunct to standard antiemetic medications for **post-myocardial infarction nausea and vomiting** significantly reduced its incidence after the first four hours.[5]
- Acupuncture stimulation of PC 6 activates the left superior frontal gyrus, the anterior cingulated gyrus, and the dorsomedial nucleus of the thalamus. It also modulates the following structures in the cerebellum: declive, nodulus, uvula of the vermis, quadrangular lobule, cerebellar tonsil, and the superior semilunar lobule. The modulation of activities in the cerebellar vestibular neuromatrix may also help explain the **antiemetic** effects of PC 6.[6]
- Transcutaneous electrical acupuncture point stimulation applied to PC 6 and CV 13 prevented **postoperative vomiting following pediatric tonsillectomy** as well as ondansetron did, but with fewer side effects.[7]
- Acupuncture with a small, indwelling needle at PC 6 effectively treated **acute vomiting** in children with gastroenteritis and pneumonia. *Klin Pediatr.* 2012;224:72-75.
- Electroacupuncture at PC 6 and ST 36 helps **control chemotherapy-induced emesis.**[8]
- Acupuncture at PC 6 was effective in treating **nausea and vomiting in early pregnancy.**[9]
- Acupressure at PC 6 was effective in relieving **morning sickness.**[10]
- A meta-analysis evaluating various means of stimulating PC 6 found that these nonpharmacologic techniques were equivalent to commonly used antiemetic drugs for the **prevention of postoperative nausea and vomiting.**[11]
- Acupuncture at PC 6 and CV 13 was as effective alternative to ondansetron for the prevention of **postoperative vomiting in children undergoing dental surgery with general anesthesia.**[12]
- Electroacupuncture at PC 6 significantly inhibited the rate of transient lower esophageal sphincter relaxations triggered by gastric distention. This suggests that electroacupuncture may help **gastroesophageal reflux disease** requires further study.[13]
- Electroacupuncture simultaneously at both PC 6 and ST 36 has a synergistic effect on **gastric myoelectrical activity.**[14]
- Transcutaneous electrical stimulation at PC 6 outperformed standard promotility medication in the treatment of **delayed gastric emptying** in critically ill patients, providing a convenient, non-invasive, safe, and inexpensive option for the prevention and treatment of malnutrition in critically ill individuals.[70]
- Acupuncture at ST 36, CV 12, and PC 6 served as an effective short- and medium-term treatment for **chronic idiopathic dyspepsia,** with fewer adverse effects and longer effectiveness than treatment with the prokinetic agent, domperidone.[15]
- Acupuncture at CV 12, ST 36, PC 6, SP 4, BL 20, and BL 21, with either the adjunct points LI 11, GB 34, and LR 3 or CV 6, CV 4, and SP 6 improved gastric emptying in a case series of patients with **diabetic gastroparesis.**[16]
- Acupuncture at LI 4, ST 36, PC 6, LR 3, CV 12, CV 17, and CV 22 successfully treated **sleep-related laryngospasm** with gastroesophageal reflux, refractory to current medical treatment; results were maintained at a 1-year follow-up assessment, and no evidence of reflux was detected upon repeated upper gastrointestinal study.[17]
- Central opioid pathways may be involved in **antiemetic effects.**[18]
- Acupuncture at PC 6 and ST 36 **lowered resting heart rate and CO_2 production.**[19]
- Acupuncture stimulation of LI 4 and PC 6 modulates heart rate variability differently under **fatigue or non-fatigue** states.[20]
- Electroacupuncture at ST 36 and PC 6 enhances **gastric motility** by affecting the migrating myoelectrical complex.[21]
- Acupuncture at PC 6 can improve left ventricular function temporarily in patients with **coronary artery disease.**[22,23]
- Electrical stimulation of the median nerve diminishes **regional myocardial ischemia** triggered by sympathetically mediated elevations in cardiac oxygen demand.[24]
- Acupuncture at PC 6 increased cardiac contraction in patients with **cardiomyopathy.**[25]

- Acupuncture at BL 14 and PC 6 caused bidirectional regulation of cardiac sympathetic and vagal nerve activities in a **cardioprotective** fashion.[26]
- Following **acute myocardial infarction,** patients receiving acupuncture at CV 14, CV 17, ST 36, PC 6, and SP 6 demonstrated the following changes: reduced blood viscosity and myocardial oxygen consumption, improved microcirculation and left ventricular function, improved collateral circulation, and reduced the area of infarction.[27]
- Electroacupuncture at PC 6, LU 2, and LU 7 may alleviate cardiac ischemia-reperfusion injury in adults undergoing **heart valve replacement.**[71]
- Acupuncture at PC 6 and HT 7 helps prevent **ventricular fibrillation secondary to myocardial** infarction in experimental rats.[28]
- Neural tracer investigation found central neural pathways from the heart and acupuncture points PC 6 and HT 7 in the middle cervical, stellate, and T4 sympathetic ganglia and the T2 to T6 spinal ganglia. Sites of overlap were also found in the brain and spinal cord, illustrating the interrelationship of PC 6, HT 7, and **autonomic regulation of heart function.**[29]
- Acupuncture at PC 6 demonstrated an **antiarrhythmic effect** in patients with both persistent and paroxysmal atrial fibrillation.[72]
- Electroacupuncture at PC 4 and PC 6 regulates blood pressure in cases of **hypotension and hemorrhagic shock.**[30,31,32,33]
- Acupuncture at ST 36, BL 15, BL 20, HT 5, and PC 6 reduced the number of attacks per week in **angina pectoris** patients and reduced ST-segment depression during exercise, possibly indicating protection of the myocardium from ischemia.[34]
- Electroacupuncture at PC 6 reduced the extent and severity of **myocardial injury** in a canine model after ligation of the coronary arteries.[35]
- Electroacupuncture at PC 6 and SP 4 significantly improved **recovery of cardiac and gastric electrical activities** after experimentally induced acute myocardial ischemia in rats, seemingly by up-regulating nitric oxide synthase expression in the myocardium as well as in the tissues of the gastric antrum and duodenum.[36]
- Manual acupuncture at PC 6 modulates **mean blood pressure and heart rate variability.**[37]
- Low level laser applied to PC 6 increased vagal activity and suppressed cardiac sympathetic nerve activity, potentially helping patients with **circadian rhythm challenges** due to taking jobs as night shift workers.[38]
- Laser stimulation of PC 6, ST 36, and LR 3 **modulated cardiovascular function** in anesthetized rats.[73]
- Acupuncture at PC 6 and ST 36 improved circadian rhythms of blood pressure in patients with **essential hypertension.**[74]
- Electroacupuncture at PC 6 improved **orthostatic tolerance** in healthy individuals by activating the sympathetic nervous system and improving cardiac function.[75]
- Acupuncture at LI 4, LR 3, and PC 6 inhibited sympathetic activation during **mental stress in advanced heart failure** patients.[39]
- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly improved **postmenopausal hot flushes and sweating episodes.**[40]
- Acupuncture at PC 6, LR 3, SP 6, LI 4, LI 11, CV 2, CV 6, CV 12, and GV 20 effectively treated **premenstrual syndrome.**[76]
- Electroacupuncture (at BL 23, BL 28, SP 6, and SP 9) in combination with manual acupuncture (at PC 6, TH 5, and GV 20) induced regular ovulations in some women with **polycystic ovary syndrome,** thereby offering an alternative to pharmacologic induction of ovulation.[41]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL2 2, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[42]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[43]
- Acupuncture needling at PC 6 resulted in a significantly reduced level of **perfusion** at the tip of the middle finger immediately after needle insertion. This was followed, after one minute, by a marked increase in peripheral perfusion.[44]
- Acupuncture at PC 6, BL 56, and GV 6 exhibited higher norepinephrine concentration in the skin and greater 3H-NE release than did stimulation of sham points. Nitric oxide (NO), an important messenger molecule, appears to be responsible for inducing these changes, acting like a neurotransmitter itself with **diverse functions** in certain circumstances.[45]
- Acupuncture stimulation of GV 14 caused hypothermia via a decrease in metabolic rate, an increase in cutaneous circulation on the back, and perspiration. In contrast, acupuncture stimulation of PC 6 or ST 36 produced a slight hyperthermia, putatively due to a decrease in **cutaneous circulation.**[46]
- Acupuncture at SP 6 produced a strong **vasoconstriction** in the ipsilateral leg and a slight vasoconstriction in the contralateral leg with no change in the arms. Stimulation of ST 36 produced a superficial vasoconstriction in the skin of both legs but no change in the arms. Stimulation of PC 6 or LI 11 caused ipsilateral vasoconstriction in the arms only. This information suggests a topographical representation in the neural segments responsible for the change in sympathetic activity.[47]
- Acupuncture at LU 7, LI 4, LI 11, ST 40, PC 3, and PC 6 resulted in immediate improvement in forced expiratory volume in 1 second (FEV1) in **asthma patients.**[48]
- Acupuncture-like transcutaneous nerve stimulation at SP 6, ST 36, LI 4, and CV 24 improves whole saliva production in patients with **radiation-induced xerostomia** in head-and-neck cancer patients treated with radical radiotherapy.[49]
- Acupuncture at LI 4 and PC 6 effectively treated acute postoperative pain in a patient with **pregnancy-induced thrombocytopenia.**[50]
- Acupuncture at LI 4 and PC 6 **increased pain threshold and pain tolerance** in the skin over the thyroid.[51]
- “Magnitopuncture” at PC 6 and GV 14 reduced the effects of **driving fatigue.**[52]

Figure 9-19. Note the proximity of the median nerve to PC 6 in this cross section. Median nerve trauma through over-vigorous needling could injure the nerve and invoke a transient neuropraxia.

- Acupuncture at LR 3, SP 6, ST 36, CV 12, LI 4, PC 6, GB 20, GB 14, Taiyang, and GV 20 provided greater effectiveness in prophylaxis of **migraine** compared to flunarizine.[53]
- Electroacupuncture from PC 5 to PC 6 **reduced the severity of hypotension** during anesthesia in patients undergoing liver transplantation, with no significant differences observed between the electroacupuncture group and those receiving norepinephrine as a vasoconstrictor.[77]
- Electroacupuncture at certain points such as PC 5 or PC 6 or LU 7 and LI 4, in addition to several others, may **improve exercise performance and post-exercise recovery.**[78]

PC 7

Da Ling "Great Mound"

On the volar aspect of the wrist, along the distal crease, on the ulnar side of the flexor carpi radialis tendon. If the palmaris longus tendon exists, PC 7 lies between it and the flexor carpi radialis tendon. Level with HT 7.

Caution: The median nerve is superficial and close to this point.[1] Needling the nerve can generate an electrical sensation. Do not traumatize the nerve through excessive stimulation.

Connective Tissues

- **Flexor retinaculum (includes the transverse carpal ligament):** Holds the flexor tendons in place. The deep part of the flexor retinaculum, called the transverse carpal ligament, attaches to the hook of the hamate and the tubercle of the trapezium bone.[5] The median nerve travels deep to the transverse carpal ligament on the radial aspect of the tunnel. While Figure 9-22 elucidates the anatomical relationships in cross section at PC 7, this is an oblique section, which changes the appearance of structures traversing this level. Nevertheless, Figure 9-22 does reveal the tight packing of tunnel contents.

The carpal tunnel, existing in two distinct parts, narrows in its distal portion, described as that section between the hamulus, or hook, of the hamate bone and the tubercle of the trapezium. The transverse carpal ligament thickens and tenses in this zone, whereas it thins and slackens at the proximal portion, between the pisiform bone and scaphoid tubercle. This allows contents inhabiting the proximal tunnel to expand. Severe or chronic carpal tunnel syndrome constricts the median nerve to such an extent that it acquires an "hour glass deformity" through the narrow zone. The palmar wrist crease

The distal tunnel contains nine tendons, including the flexor pollicis longus and superficial and deep digital flexors for each of the four fingers, making for a crowded channel coursing beneath the transverse carpal ligament. The flexor carpi radialis tendon occupies its own osteofibrous tunnel.

Fibers from thenar and hypothenar muscle fascia join and blend with dorsal fascia of the palmaris brevis muscle to create a fascial plane superficial to the transverse carpal ligament.[6] Preserving this connective tissue bridge, should surgery prove to be necessary, maintains pinch strength.

Clinical Relevance: Entrapment likely results from the narrowness of the distal carpal tunnel, combined with the thickness and tension of the transverse carpal ligament in this section, impacting the tunnel's contents. Thus, releasing restrictions with acupuncture and related techniques can reduce the pain and numbness that accompanies carpal tunnel syndrome.

The location of PC 7 at the palmar wrist crease places the point at the proximal border of the transverse carpal ligament, where more space exists for tunnel contents, in contrast to the distal region. Thus, treatment for carpal tunnel constriction should follow the course of the PC line to free the tissue of the narrow part, between PC 7 and PC 8. Consider, too, the location of PC 7 between the flexor carpi radialis and the tunnel. This places the point atop the transverse carpal ligament, where it bridges from the palmar fascia to the trapezium.

Tendons

- **Flexor digitorum superficialis tendon:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints.
- **Flexor digitorum profundus tendon:** Flexes the distal phalanges

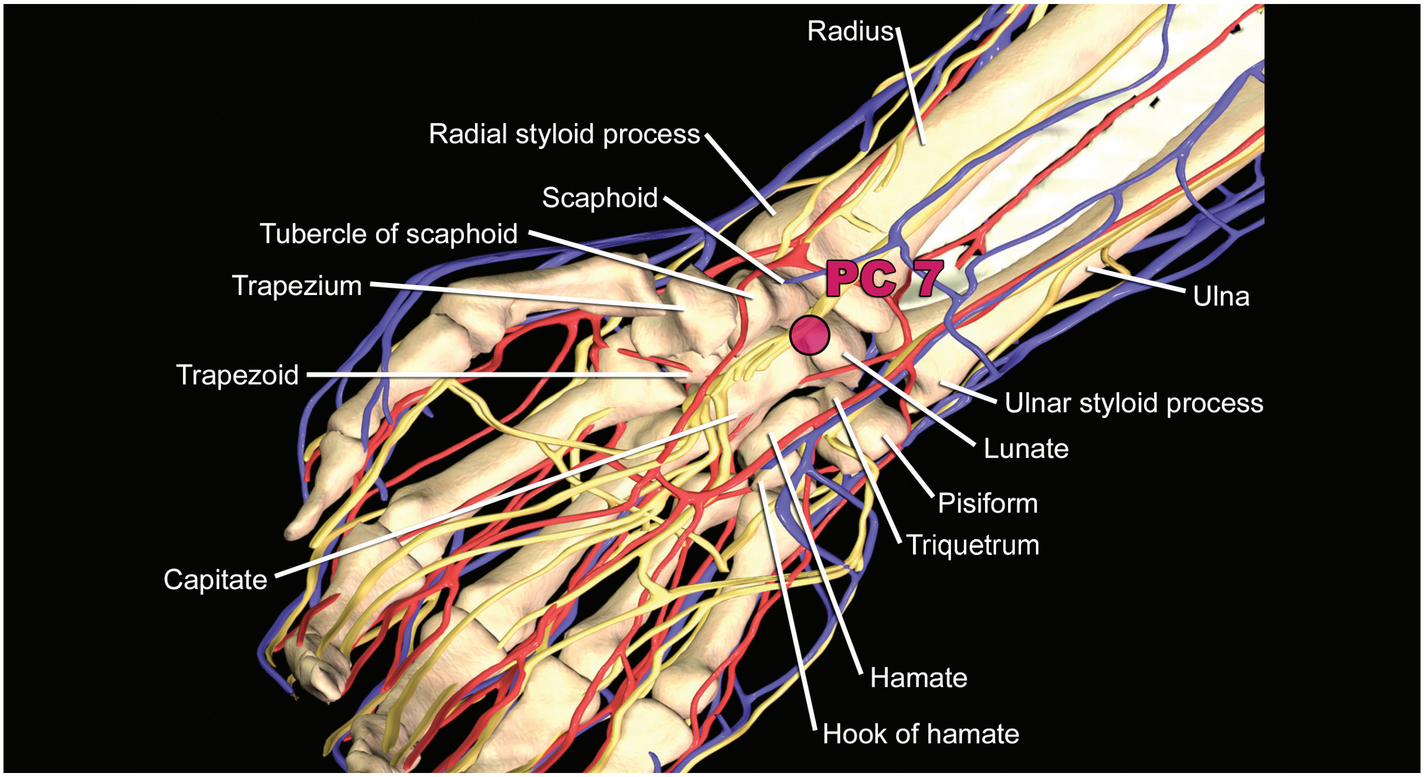

Figure 9-20. The proximity of the median nerve to PC 7 explains its pre-eminence in acupuncture approaches for carpal tunnel syndrome.

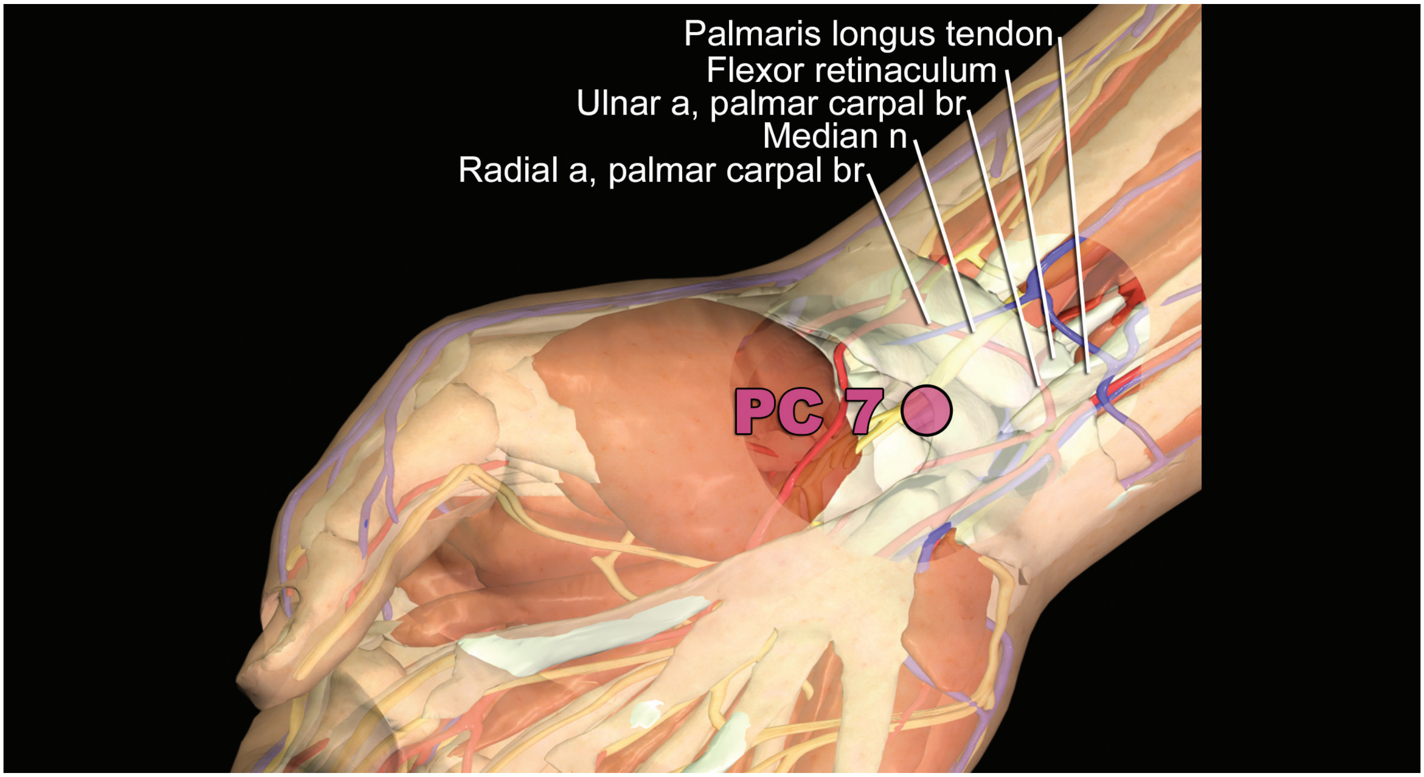

Figure 9-21. This semi-transparent muscle layer illustrates the neurovascular anatomy relevant to PC 7, namely the median nerve and the communicating branches between the radial and ulnar arteries. Dynamic wrist motion changes the position of neurovascular and tendinous structures within the carpal tunnel, arguing for employing appropriate therapeutic exercises and manual therapy treatments to maintain free mobility of these structures to avoid compression and sidestep surgery.[25]

of the fingers at the distal interphalangeal joints.

- **Palmaris longus tendon:** Tightens the palmar aponeurosis and flexes the hand at the wrist.
- **Flexor carpi radialis tendon:** Flexes and abducts the hand at the wrist. The flexor carpi radialis tendon sits outside the carpal tunnel, separated from it by a deep portion of the transverse carpal ligament.[7]

Clinical Relevance: Trigger point pathology in the following muscles at or near PC points on the proximal forearm lead to their respective pain referral patterns, which may follow tendons traveling toward the wrist:

- **Flexor digitorum superficialis and profundus:** Radial head of each muscle group refers pain to the palmar middle finger from PC 8 to PC 9.
- **Palmaris longus:** Pain from a palmaris longus trigger point just proximal to PC 4 sends pain along the PC channel to the palm between PC 8 and HT 8, where it centralizes.
- **Flexor carpi radialis:** Issues pain along the PC channel to the wrist, centered strongly over PC 7 and spilling toward LU 9. At times, extends to the palm near PC 8.

In addition, a myofascial trigger point in the medial head of the triceps can cause pain to travel from the elbow at PC 3-HT 3 where it localizes strongly. The pain pattern then extends down the PC/HT line to the ring finger and pinky.

Patients with anomalous muscles, tendons, or fibrous bands linking structures together, accentuate median nerve compression.[8]

Note how, as Figure 9-21 reveals, the palmaris longus tendon expands at the level of PC 7 into the fascia of the thenar eminence. This distal fascial feature along the superficial flexor surface of the thoracic limb joins the tendon to the palmar aponeurosis. The myofascial continuum expressed in acupuncture as the PC channel thereby extends from the pectoralis major muscle (PC 1) to the medial intermuscular septum of the brachium (PC 2), over the cubital fossa to the flexor digitorum superficialis and palmaris longus. This final connection to the palmar aponeurosis brings the connective tissue out toward the fingers.

Traction along the axis of the palmaris longus tendon pulls upon the palmar and thenar fasciae. Releasing this region with manual therapy or stretching may alleviate stiffness and the neurovascular compression it can cause. The propagation of impulse along fascial planes with acupuncture can induce channel effects from distal thoracic limb to the upper chest, where the PC line began.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm. A branch of the ulnar nerve.
- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the radial volar aspect of the forearm, and a portion of the dorsal radial aspect of the distal forearm.
- **Median nerve (C6-T1):** Muscular branches supply the pronator teres and pronator quadratus muscles and all of the forearm flexors (including the flexor carpi radialis, the palmaris longus,

and the flexor digitorum superficialis muscles), except the flexor carpi ulnaris and medial half of the flexor digitorum profundus muscle. The median nerve innervates all of the thenar muscles except for the adductor pollicis and deep head of the flexor pollicis brevis. Also supplies the lumbrical muscles for digits II and III, and provides sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (thumb, forefinger, and middle finger), along with the radial aspect of the ring finger, as well as the adjacent palmar areas. Four branches arise from the median nerve: the recurrent (thenar), lateral, medial, and palmar cutaneous. The recurrent branch supplies the abductor pollicis brevis, the opponens pollicis, and the superficial head of the flexor pollicis brevis. The lateral branch supplies the 1st lumbrical, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.

The median nerve enters the carpal tunnel midway between the radius and ulna or slightly radial of midline. Its position within the tunnel shifts in accordance with hand movement. Anatomical variations of the median nerve include accessory branches including nerve duplications. The thenar branch of the median nerve most often separates distal to the transverse carpal ligament, but it may instead perforate the flexor retinaculum through its own tunnel.[9]

- **Anterior interosseous nerve:** Arises from the median nerve. Supplies the flexor digitorum profundus, the flexor pollicis longus, and the pronator quadratus muscles. Also supplies the anterior surface of the interosseous membrane.

Clinical Relevance: Proximal to the wrist, the median nerve sits deep within the volar antebrachium, sandwiched between the superficial and deep digital flexor muscles. Between PC 6 and PC 7, the nerve curves around the lateral aspect of the superficial digital flexor to rest atop or adjacent to the tendon bundle at the wrist (see Figure 9-22). The nerve then enters the carpal tunnel, risking entrapment, except for its superficial palmar nerve branch. This cutaneous branch of the median nerve circumvents the carpal tunnel and thus sidesteps the problem.

Isolated anterior interosseous nerve compression may occur after repetitive movement involving flexion of the elbow and/or pronation of the forearm.[1] Injury of the anterior interosseous nerve manifests as weakness in interphalangeal joint flexion or paresis of the distal interphalangeal joints of the index and middle fingers.[10] Pain arises in the volar antebrachium; people with isolated anterior interosseous neuropathy cannot make the “ok” sign with the thumb and forefinger, making a pinching movement with these digits. Handwriting also becomes difficult.[11]

Compression of the anterior interosseous nerve occurs along the course of the PC channel and follows trauma, iatrogenic injury (dressings, slings, venipuncture), and elbow or shoulder arthroscopy. Anatomic sources of compression include: 1) the tendinous origin of the deep head of either the pronator teres or flexor digitorum superficialis to the middle finger; 2) a site of thrombosis of the ulnar collateral vessels crossing the anterior interosseous nerve; 3) accessory muscles or tendons of the flexor digitorum superficialis or the flexor pollicis longus (i.e., Gantzer’s muscle); 4) an aberrant radial artery; 5) tendinous portions of the palmaris longus or flexor carpi radialis brevis muscles, or 6) an enlarged bicipital bursa in the vicinity of PC 3.

Entrapment sites of the anterior interosseous and median nerves resemble one another because they pursue parallel trajectories. No matter which nerve becomes compressed, physical medicine can improve the symptoms by releasing the dysfunction at the heart of the entrapment.

Median nerve stimulation itself may prove therapeutic for a number of conditions. First and foremost, neuromodulation of the median nerve facilitates its recovery from the problems described above, wherein chronic pressure compromises nerve health. In addition, median nerve stimulation affords an array of homeostatic effects based on its neuromodulation of rostral ventrolateral medulla (RVLM) function. The RVLM affects cardiopulmonary physiology; neuromodulation through physical medicine modalities modulates cardiovascular excitatory responses.[12] Acupuncture points along the median nerve regulate blood pressure and protect against hypotension. Stimulation of PC 5 and PC 6 also alters cardiovascular function by acting on the cholinergic neurons in the nucleus ambiguus, likely by means of enkephalinergic pathways.[13]

Median nerve stimulation also treats causalgia, otherwise known as complex regional pain syndrome type II (CRPS II).[14] It also reduces neuropathic pain in cases of median nerve damage following carpal tunnel surgery.[15]

Chronic regional pain disorders typically exhibit autonomic features such as vasomotor or sudomotor dysfunction. CRPS type I (reflex sympathetic dystrophy) produces: skin color changes, edema, abnormal sweating (sudomotor activity), regional pain, dysesthesia, temperature changes, and a history of trauma or a noxious event. CRPS type II adds a peripheral nerve lesion such as neuroma. Peripheral nerve stimulation provided by acupuncture and related techniques should precede implanted nerve stimulators or spinal cord stimulation, in that the non-invasive neuromodulation affords a safer and more comfortable method of fostering nerve repair and analgesia.

Vessels

- **Anastomosis between palmar carpal branches of radial and ulnar arteries:** The carpal arterial arch joins the radial and ulnar arteries.
- **Superficial venous palmar arch:** Joins tributaries of the basilic and cephalic veins.

Clinical Relevance: Superficial and deep vascular networks supply the flexor retinaculum at the wrist.[16] The superficial network arises from branches of the ulnar artery. The deep network forms from branches of the palmar superficial arch. Vessels traversing the wrist at the level of PC 7 are at risk of iatrogenic damage during carpal tunnel surgery. Anatomic variations of the ulnar artery place the vessel at heightened risk of injury during transverse carpal ligament resection.[17] Acupuncture, laser therapy, and manual treatment of the region may aid in patient recovery by benefiting local circulation.

Up to one quarter of patients undergoing surgical carpal tunnel release experience complications and/or treatment failure.[18] Causes of complications include hematoma, skin necrosis, iatrogenic injuries intraoperatively, and infection. Incomplete decom-

pression can cause persistent problems, as can intraneural or perineural scarring. If conservative treatment for carpal tunnel syndrome with physical medicine maneuvers fails and surgery seems to be the only remaining option, acupuncture and laser therapy should strongly be considered to limit the amount of necrosis and circulatory compromise following tunnel release. These approaches also aid in accelerating the resolution of neuropathic pain and sensory dysfunction.

Indications and Potential Point Combinations

- **Local wrist pain:** Identify the source of pain; if palmar and tender at PC 7, consider trigger point in the flexor carpi radialis or pronator teres (treat PC 7 and LU 9).Trigger point in the palmaris longus muscle radiates to the palm; treat palmaris longus trigger point, PC 6, PC 7, PC 8 (if tolerated). For radial wrist pain, consider PC 7, LU 9, LU 10, and LI 4 for opponens pollicis trigger.
- **Carpal tunnel syndrome:** PC 7, PC 6, LU 9, HT 7. Rule out other sources of median nerve entrapment. Consider laser therapy and massage to PC 8.
- **Anxiety or depression:** PC 7, CV 17, ST 36.
- **Insomnia:** PC 7, TH 5, HT 7, HT 3, GV 20, LR 3, ST 36, CV 4.[19]
- **Heel Pain:** PC 7, local points tender to palpation and involved in nerve entrapment referring to the heel.[20]

Evidence-Based Applications

- Laser at PC 7, TENS at TH 4/PC 7, laser at Ting points on the hand, and laser at LU 9, HT 7, HT 8, PC 8, and Baxie significantly reduced pain in patients suffering from **carpal tunnel syndrome.** Patients' scores on the McGill Pain Questionnaire decreased significantly, as did median nerve sensory latency and Phalen and Tinel signs.[2]
- Patients with **chronic neck pain** who received electrical stimulation at acupuncture points on the wrist, including PC 7, experienced significant improvements over sham treatment with no adverse effects.[3]
- Acupuncture at PC 7 and PC 6 produced significantly better improvement in symptoms as well as distal motor and sensory latencies for patients with **carpal tunnel syndrome** than did oral steroid medication. These results continued through the 1- year follow-up period.[21]
- Acupuncture applied to PC 6 and PC 7 significantly improved nerve conduction velocity and symptoms in patients with **carpal tunnel syndrome.**[22]
- Acupuncture at PC 7, TH 4, TH 5, and Baxie, along with moxibustion at LI 11 and Tuina (Chinese massage) to the wrist, reduced symptoms and improved function in patients with **carpal tunnel syndrome.**[23]
- Electroacupuncture at 15 Hz at PC 7 increased **dopamine** release in the striatum of rats, while the same stimulation at HT 7, LU 9, TH 5, and LI 5 did not.[4]
- Acupuncture needling of PC 7 reduced reported morning pain in patients with suspected **plantar fasciitis** significantly more than needling did when applied to LI 4.[24]

PC 8

Lao Gong "Palace of Toil"

On the palm of the hand, between the 2nd and 3rd metacarpal bones, in a depression on the radial aspect of the third metacarpal bone. Can be found where the tip of the middle finger touches the palm when a tight fist is made.

Fascia

- **Palmar aponeurosis:** The strong palmar aponeurosis constitutes the deep fascia over the palm. It covers and protects the nerves and vessels; it also maintains the transverse arch of the transverse carpal ligaments. Its distal fibers function as a pulley on the flexor tendons. It assists in forming a cup with the hand by means of its attachments to the metacarpal bones.

The palmar aponeurosis joins the palmaris longus tendon at the level of the distal transverse wrist crease,[3] or PC 7. The palmaris longus, a thin, highly variable, accessory muscle of the forearm, helps tense the palmar aponeurosis, contributing to wrist flexion.[1] The palmaris longus influences the longitudinal orientation of fibers in the superficial layer of the palmar aponeurosis through the tension it places on the fascia.

Clinical Relevance: Tension along the palmaris longus tendon influences fiber direction in the palmar aponeurosis, causing a more regularly arranged longitudinal orientation.[4] This may explain why the presence of the palmaris longus tendon correlates with increased risk of developing Dupuytren's disease.

Muscles and Tendons

- **Flexor digitorum superficialis tendon:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints.
- **Flexor digitorum profundus tendon:** Flexes the distal phalanges of the fingers at the distal interphalangeal joints.
- **2nd lumbrical muscle:** The four small lumbrical muscles originate from the deep digital flexor tendons. Flexes the digit at the metacarpophalangeal joint and extend the interphalangeal joint. The lumbrical muscles of the hand contribute indirectly to interphalangeal joint extension by regulating flexion force of the deep digital flexor.[5]
- **1st palmar interosseous muscle:** Adducts the digits toward the axial line. Assists the lumbrical muscles in extending the interphalangeal joints and flexing the metacarpophalangeal joints.
- **2nd dorsal interosseous muscle:** Abducts digits from the axial line. Acts with the lumbrical muscles to extend the interphalangeal joints and to flex the metacarpophalangeal joints.

Clinical Relevance: Trigger point pathology in the following muscles at or near PC points on the proximal forearm lead to their respective pain referral patterns, which may follow tendons traveling toward the wrist:

  - **Flexor digitorum superficialis and profundus:** Radial head of each muscle group refers pain to the palmar middle finger from PC 8 to PC 9.
  - **Palmaris longus:** Pain from a palmaris longus trigger point just proximal to PC 4 sends pain along the PC channel to the palm between PC 8 and HT 8, where it centralizes.
  - **Flexor carpi radialis:** Issues pain along the PC channel to the wrist, centered strongly over PC 7 and spilling toward LU 9. At times, extends to the palm near PC 8.

In addition, a myofascial trigger point in the medial head of the triceps can cause pain to travel from the elbow at PC 3-HT 3 where it localizes strongly. The pain pattern then extends down the PC/HT line to the ring finger and pinky.

Patients with anomalous muscles, tendons, or fibrous bands linking structures together, accentuate median nerve compression.[6]

Note how, as Figure 9-23 reveals, the palmaris longus tendon adjoins the palmar aponeurosis and extends to PC 8, linking the line from pectoralis muscle to the palm, thereby creating the connective tissue component of the PC channel.

Traction along the axis of the palmaris longus tendon creates lines of force in both the palmar and thenar fasciae. Thus, releasing these connective tissue elements with massage, acupuncture, laser therapy, or stretching may alleviate neurovascular compression and stiffness of the wrist or hand.

The lumbrical muscles work in concert with the interosseous muscles to perform finely coordinated movements of the fingers.[7] They assist in regulating flexion and extension of the intrinsic and extrinsic muscles attaching to the fingers. Consequently, myofascial restriction can compromise dexterity and strength in the hand. The palm contains abundant sensory nerve endings; as such, patients will tolerate massage and laser therapy at PC 8 more readily than acupuncture needling.

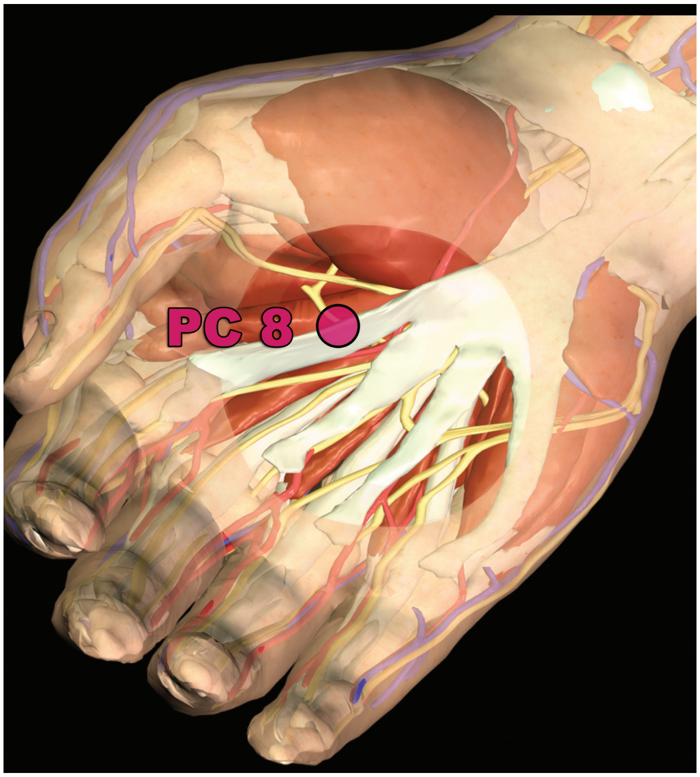

Figure 9-23. PC 8, the "Palace of Toil", falls on the "palace of toil" in the hand, i.e., the palm. An alternate descriptive name for PC 8 is "Labour Palace", also self-explanatory.

Figure 9-24. The deforming, fibrotic condition of the palmar fascia known as "Dupuytren's contracture" arises as a result of fibroblast proliferation, possibly related to a sustained relative ischemia in the region.[13] Acupuncture stimulation at PC 8 could improve local blood flow. Thus, it may impact pathogenesis of the disease. Dry needling, massage, and laser therapy may relax tension on the palmaris longus muscle that would otherwise worsen the contracture. Excessive and sustained tension on the palmar aponeurosis reorganizes the cytoarchitecture of the palmar aponeurosis, potentially predisposing patients to Dupuytren's contracture.

Figure 9-26. This cross section exposes the relationship between PC 8 and the adductor pollicis muscle. Trigger points in the adductor pollicis muscle may respond to PC 8 needling or acupressure (given the sensitivity of the palm).

Nerves

- **Median nerve (C6-T1):** The median nerve innervates all of the thenar muscles except for the adductor pollicis and deep head of the flexor pollicis brevis. Also supplies the lumbrical muscles for digits II and III, and provides sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (thumb, forefinger, and middle finger), along with the radial aspect of the ring finger, as well as the adjacent palmar areas. Four branches arise from the median nerve: the recurrent (thenar), lateral, medial, and palmar cutaneous. The recurrent branch supplies the abductor pollicis brevis, the opponens pollicis, and the superficial head of the flexor pollicis brevis. The lateral branch supplies the 1st lumbrical, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.

Clinical Relevance: PC 8 serves as a useful distal point in cases of more proximal median nerve entrapment. In the distal antebrachium, the median nerve occupied a deep position along the volar antebrachium, sandwiched between the superficial and deep digital flexor muscles. Between PC 6 and PC 7, the nerve curved around the lateral aspect of the superficial digital flexor to rest atop the tendon bundle at the wrist (see Figure 9-25). The median nerve travels through the carpal tunnel, at risk of entrapment, except for its superficial palmar nerve branch, which may circumvent the tunnel.

The recurrent branch of the median nerve is susceptible to entrapment where it pierces the transverse carpal ligament or wraps around the distal aspect of the ligament. Branches of the median nerve that supply the index, middle, and ring fiber pass between metacarpal heads through metacarpal tunnels.[8] Activities involving digital extension at the metacarpophalangeal joints can compress the digital nerves against deep transverse metacarpal ligaments. Vibrating tools such as jackhammers may damage these nerves through repeated, blunt trauma.

Vessels

- **Superficial palmar arterial arch:** The direct continuation of the ulnar artery. Meets the radial artery on the radial aspect of the hand.
- **Common palmar digital artery:** Arises from the superficial palmar arch. Courses toward the web between the digits, where it branches into the proper palmar digital arteries. These arteries give off dorsal branches that supply the nail beds.

Clinical Relevance: Ischemic events affecting the palm (including PC 8 and HT 8) may require incorporation of lumbrical muscles into replantation or revascularization flaps.[9] Arteries supplying the lumbrical muscles originate directly from the superficial palmar arch or the common palmar digital artery. The 2nd lumbrical muscle, beneath PC 8, receives blood supply mainly from the superficial palmar arterial arch, the 1st common palmar digital artery, and the 3rd palmar metacarpal artery. As it can prove difficult or impossible to repair minute vessels supplying the lumbrical and interosseous muscles at certain areas of their supply chain, injuries to the vasculature of the hand, whether traumatic or iatrogenic, may compromise muscular health and, consequently, function.[10]

Furthermore, variations in arterial arch anatomy lead to vascular damage during surgical harvesting of radial arteries as an arterial bypass conduit.[11] Physical medicine maneuvers support repair of vessel recovery and regrowth.

Indications and Potential Point Combinations

- **Paresis or paralysis of the thoracic limb:** PC 8, Baxie points (in the web spaces between the fingers), LI 4, and neuroanatomically appropriate points based on nature of neurologic compromise.
- **Superficial prickling pain in the forearm radiating to the palm:** PC 8, PC 7, trigger point in the palmaris longus muscle, which may occur in the vicinity of PC 4 or at other locations along the palmaris longus muscle and tendon.
- **Dupuytren's contracture:** PC 8, PC 7, trigger point in the palmaris longus muscle (in the vicinity of PC 4), or elsewhere along the palmaris longus muscle and tendon.[2]
- **Sympathetic activation, mania, high fever:** PC 8, LR 3, GV 14, GV 20, KI 1.
- **"Weeder's thumb", or trigger points in the adductor and opponens pollicis muscle:** PC 8, LI 5, and LI 4 (to treat the adductor pollicis muscle and its radiation pattern) and/or LU 10 and LU 9 (for opponens pollicis trigger point and referred pain pattern).

Evidence-Based Applications

- Transcutaneous electrical acupuncture point stimulation from LI 4 to PC 8 and PC 6 to TH 5 reduced the urge to smoke in **addicted cigarette smokers.**[12]

PC 9

Zhong Chong “Middle Rushing”, “Central Rush”, “Central Hub”, “Central Surge”

On the radial nail angle of the 3rd digit, the width of a Chinese leek leaf from the corner of the nail. (Some sources locate the point at the center of the tip of the middle finger.)

Nerves

- **Median nerve (C6-T1):** The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. (Supplies the radial aspect of the dorsal tip of the ring finger.) Distal branches of the proper palmar digital nerve from the median nerve provide sensation and sympathetic input to the middle finger.
- **Note about fingertip nerve supply:** The highly sensate fingertip contains sensory end organs between the volar digital skin and the nail that allows for accurate prehension of small objects. The proper palmar digital nerve accompanies its arterial companion on the ventral ulnar and radial aspects of the fingers. Proximal to the base of the nail fold, the nerve divides and sends branches into the pulp of the finger as well as to the nail bed. These nerve fibers provide only part of the sensory supply to the nail bed. Additional sensation is supported by structures known as “glomus bodies”, identified as intertwining clusters of fine vessels and nerves. Glomus bodies modulate blood flow to the fingertip by controlling fine vessel diameter. The close proximity of glomus bodies to the nail allows for thermal transfer, similar to the heat exchange that takes place when one places a hand against a window pane. Too, the finger’s tip serves as a temperature regulator, highlighting the indications of Ting points such as PC 9 for heat stroke and fever.

Clinical Relevance: This point treats distal middle finger numbness or nerve damage. It can intensely activate autonomic reflexes influencing attention and arousal as well as heat distribution. It also accentuates autonomic reflexes to the cardiopulmonary centers via brainstem circuits that reflex between the median nerve and the rostral ventrolateral medulla.

Vessels

- **Dorsal branches of proper palmar digital artery of the radial side of the 3rd digit:** Arise from the proper palmar digital arteries, which in turn arise from the superficial palmar arterial arch, which comes from the ulnar artery.

Clinical Relevance: The rich arteriovenous supply of the distal finger offers opportunities to induce profound autonomic shifts in hemodynamics and alertness, seemingly disproportionate to the vessels’ sizes in this region.

Indications and Potential Point Combinations

- **Hypotension, syncope:** PC 9, LI 5.
- **Pain in middle finger, palmar aspect from trigger point(s) in the flexor digitorum muscles affecting the middle finger:** PC 9, Baxie (web space points) on either side of middle finger, trigger point in the radial head of the flexor digitorum superficialis and profundus at about PC 4.
- **Pain in middle finger, dorsal aspect from trigger point(s) in the extensor digitorum muscle extending the middle finger:** PC 9, Baxie (web space points) on either side of middle finger, trigger point in the extensor digitorum muscle in the vicinity of TH 9, TH 4, TH 5.
- **Post-stroke coma:** PC 9, PC 8, GV 20, GV 16, LI 4, ST 36.
- **High-fever neurologic complications:** PC 9, PC 8, PC 6, GV 20, LR 3.

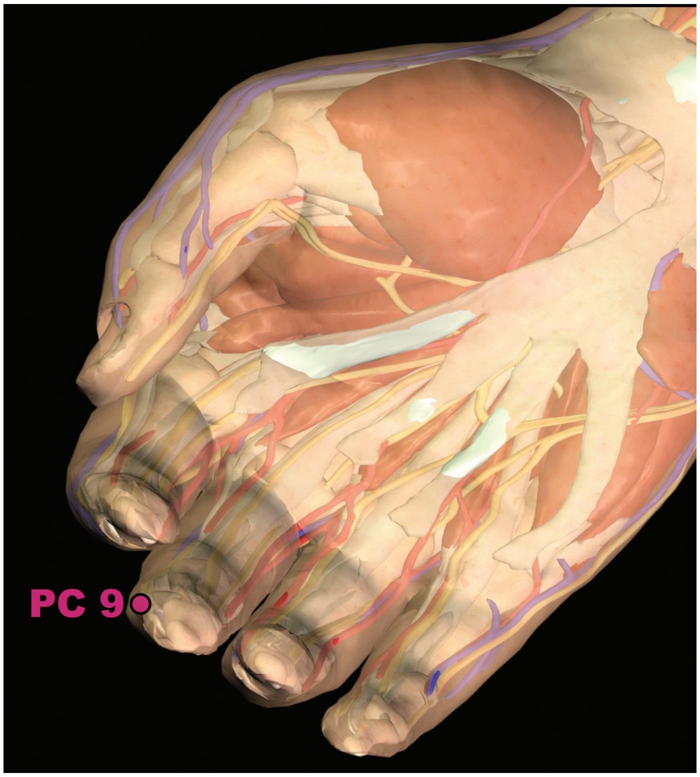

Figure 9-27. TThe centrality of the middle finger and the turbulence of blood flow from the arterial to the venous system provide insight into the names for PC 9 such as “Middle Rushing” and “Central Surge”.

TH 1

Figure 9-29. The neurovascular correlates for PC 9, like the other Ting, or most distal points of channels that land on the fingers and toes are the dorsal branches of the proper palmar/plantar digital arteries and their accompanying nerves. 4 In the cases of LU 11, LI 1, and PC 9, the nerve supply originates in the median nerve. This depiction compares the neurovascular supply of PC 9 (in its standard location) to TH 1, the start of the next channel. Whereas PC 9 carries median nerve innervation, TH 1 derives its sensory supply from the ulnar nerve.

The TH channel begins on the ulnar aspect of the ring finger. It wends its way between the 4th and 5th metacarpals, then sinks into the interosseous groove between radius and ulna. Proximal to the elbow, the TH line journeys over the dorsal brachium to the acromion process. It ascends to the mastoid process, encircles the ear, and arches over the temporal region to the lateral eyebrow, where it ends at TH 23.

Muscles along the TH channel extend the pinky, ring finger, carpus, elbow, shoulder, and neck. They move the ear, the temporomandibular joint, and the eyebrow. These muscles work in concert when a musician plays a violin, resting the rostral mandible on the chinrest, supporting the instrument with the shoulder, holding the elbow in partial extension, and placing the fingers on the strings. One listens for good intonation with the ear and watches the conductor or reads music with the eye. Actions of the extensors on the right hand arm, and shoulder move the bow and bear responsibility for tone quality, dynamics, rhythm, and much of the timbre. The line these muscles describe (TH channel) appear in the following two images.

TH 1

Guan Chong "Rushing Pass", "Passage Hub", "Impetuous Pass"

Located on the ulnar aspect of the 4th digit, level with the base of the nail, the width of a Chinese leek leaf from the corner of the nail. In other words, TH 1 resides at the nail angle of the ulnar aspect of the 4th ring finger.

Nerves

- **Dorsal branches of proper palmar digital nerve:** Arise from the ulnar nerve (C8-T1). The dorsal branches of the proper palmar digital nerves supply branches to the dorsum of the tip of the little finger and nail bed, and the ulnar aspect of the ring finger.

Clinical Relevance: Stimulation of TH 1 activates the C8/T1 spinal cord segments, where the sympathetic cell column in the spinal cord begins. As the most distal point on the TH channel, TH 1 receives the richest autonomic innervation per unit area of any TH point on the thoracic limb. Initial sympathetic activation may induce a reflex parasympathetic response.[2]

Vessels

- **Dorsal branches of proper palmar digital artery of the ulnar side of the 4th digit:** The dorsum of the fingertip receives arterial blood supply from the dorsal branch of the proper palmar digital artery which arises from the superficial palmar arterial arch. The distal (ting) points on each channel that begins or end on a digit signify locations where vessels from either side of the finger form anastomotic branches across the dorsum.[1] The dorsal branch of the proper palmar digital artery provides vascularization to the flexor and extensor tendons as well as the interphalangeal joint and skin of the fingertip.

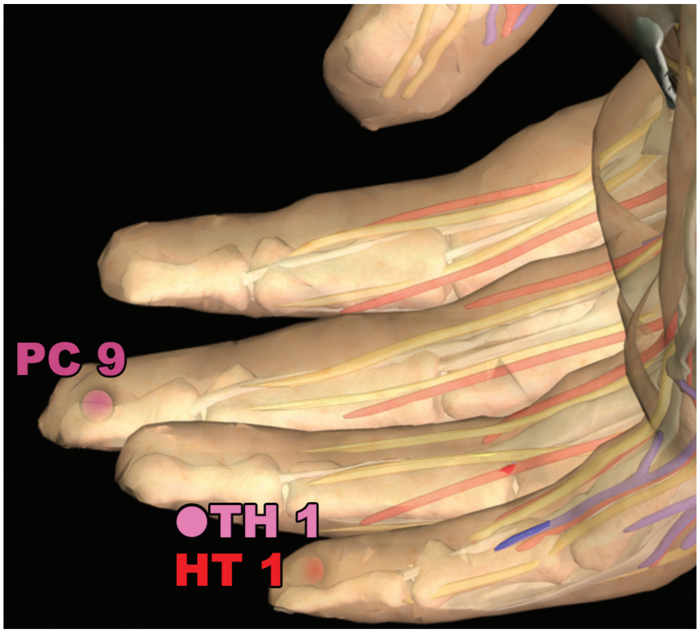

Figure 10-1. The term "Passage Hub" describes the location of TH 1 as a distal point between two other significant sites: PC 9 ("Central Hub" or "Central Surge") and HT 9 ("Lesser Surge").

Clinical Relevance: Autonomic fibers from the ulnar nerve become the nervi vasorum of arterioles at TH 1. These afferents connect to autonomic centers in the brain and spinal cord that regulate autonomic tone. Sympathetic fibers stimulated by needling TH 1 may inspire a reflex parasympathetic response.[3]

Indications and Potential Point Combinations

- **Forearm pain:** Search for trigger points along the ulnar aspect of the ring finger's digital extensor muscle. TH 1, TH 9, LI 10, local trigger points.
- **Syncope:** TH 1 is one of several Ting points on the fingers known to arouse the sympathetic nervous system. At least initially, they offset vagovagal reactions. After several minutes, parasympathetic activity may follow.[4]

Distal phalanx, 4th digit

Figure 10-2. Trigger points in proximal ring-finger extensor muscle occur in the vicinity of TH 9 and LI 10. They issue pain along the TH line to the ring finger toward TH 1.

TH 2

Ye Men "Fluid Gate" or "Humor Gate"

On the dorsum of the hand, distal to the 4th and 5th metacarpophalangeal joints, approximately 0.5 cun proximal to the web margin, at the dorsal/palmar skin junction. Can be found at the proximal end of the crease formed by the web space when the hand makes a loose fist.

Tendons

- **4th lumbrical tendon**: Flexes the digit at the metacarpophalangeal joint and extend the interphalangeal joint.
- **3rd palmar interosseous tendon:** Adducts the digits toward the axial line. Assists the lumbrical muscles in extending the interphalangeal joints and flexing the metacarpophalangeal joints.
- **4th dorsal interosseous tendon:** Abducts digits from the axial line. Acts with the lumbrical muscles to extend the interphalangeal joints and to flex the metacarpophalangeal joints.

Clinical Relevance: Myotendinous dysfunction in the vicinity of TH 2 may cause difficult or painful ring or little finger movement. Acupuncture, massage, and laser therapy may improve symptoms arising from degenerative joint disease or other causes of arthralgia and arthrosis of the 4th and 5th metacarpophalangeal joints.

Pain at TH 2 may manifest from local or proximal trigger point pathology. A trigger point in the ring finger extensor near TH 9 typically refers pain to the region around TH 2, connecting a line from TH 2 to LI 11. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles can also refer pain to TH 2. Because of the multiplicity of causes of perceived pain in this region, a complete myofascial palpation exam should elucidate myriad contributors to ulnar hand pain.

Grasping and releasing objects with the hand and fingers constitute key components of the activities of daily living. Several pathologies reduce manual dexterity and limit functional independence. Neuromodulation of motor dysfunction assists in the repair of these movements for patients following cerebrovascular accident.[1] In patients afflicted with this problem, palpate all muscles from the neck and back to the fingers. Pay close attention to restriction found in the intrinsic muscles of the hand, the extensor digitorum communis (common digital extensor), flexor pollicis longus, and thenar muscle group. Needle, stretch, massage, and laser the regions accordingly.

Nerves

- **Common palmar digital branches of the superficial branch of the ulnar nerve:** Supply sympathetic motor innervation to the palmar and dorsal skin of the little finger and ulnar half of the ring finger.

TH 4
TH 3
TH 2

Figure 10-3. The web space placement of TH 2 overlaps with one of the Baxie points' locations, which exist in the four web spaces on each hand. The term "Baxie" connotes the eight "evils" that were thought to enter at these sites and cause pain. The branching neurovasculature here makes it ideal for modulating nerve signals and blood flow to the two ulnar–innervated fingers. The branching metacarpal nerve forms a target for somatic afferent stimulation designed to recover motor and sensory nerve communication between the spinal cord and hand, as in the cases of peripheral nerve injury, cervical disk disease, and cerebrovascular accident. A Chinese needling technique connecting TH 2 to TH 3 has been advocated for disorders manifesting on the head and neck along the TH channel.[2] However, threading a needle from one point to another may prove to be unacceptably invasive and risky for patients considering the modern medical and legal environments.

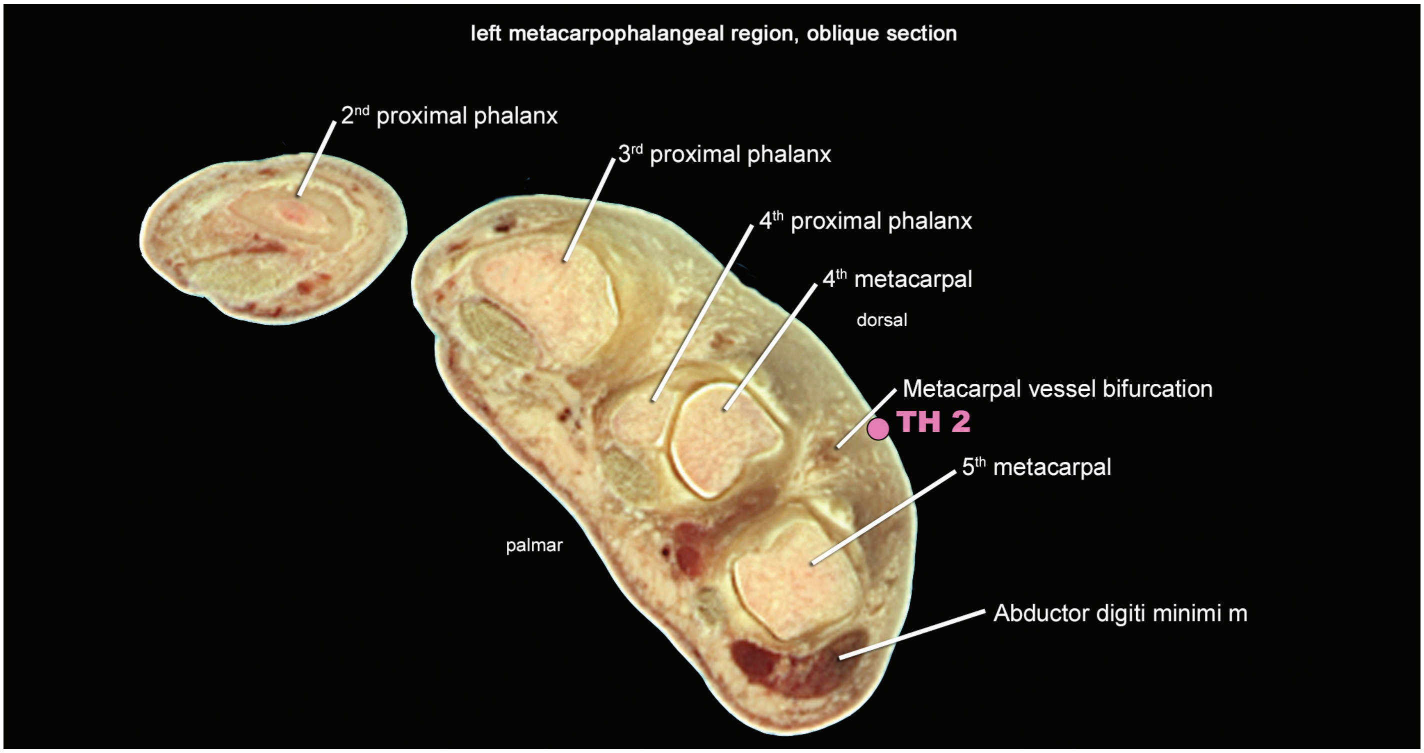

Figure 10-4. TH 2, also named "Fluid Gate" or "Humor Gate", provides a passageway of blood to the fingers, explaining the reference to liquid and the humors it contains as it courses through the body. This image demonstrates how the bifurcation of the vasculature at this point, mirrors that of the nervous system into digital branches.

- **Dorsal digital nerves:** Supplies the ulnar aspect of the ring finger, derived from the ulnar nerve.
- **Ulnar nerve (C8-T1):** The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, and the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: TH 2 coincides with the division of the fourth metacarpal nerve into two digital branches. As such, this point serves as a distal site for neuromodulation of problems related to hand and finger discomfort affecting the ulnar side of the hand and wrist.

Vessels

- **Dorsal metacarpal artery:** Arises from the dorsal carpal arch and receives contributions from the superficial palmar arch via perforating branches.
- **Dorsal digital arteries:** The dorsal metacarpal artery divides into two dorsal digital arteries at the metacarpophalangeal region.
- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.

Clinical Relevance: Acupuncture and related techniques implemented along the distal TH line may improve circulation for patients with peripheral vascular disease affecting ring or little finger mobility and/or tissue health.

Indications and Potential Point Combinations

- **Fever with nausea and sore throat:** TH 2, PC 6, CV 22.
- **Earache:** TH 2, TH 20, TH 21, GB 20.
- **Stiffness or pain in the hand:** TH 2, explore extensor digitorum bundle to the ring finger at about TH 9, TH 4.
- **Compromised nerve function of the thoracic limb or hand:** TH 2, Baxie, specific points related neuroanatomically to the peripheral nerve and spinal cord segments involved in the dysfunction.

TH 3

Zhong Zhu "Central Islet"

On the dorsum of the hand, in a depression just proximal to the 4th and 5th metacarpophalangeal joints. Locate the point with the hand making a loose fist. This point, along with the prominences of the 4th and 5th metacarpophalangeal joints creates an equilateral triangle.

Muscles

- **4th lumbrical muscle:** Flexes the digit at the metacarpophalangeal joint and extends the interphalangeal joint.
- **3rd palmar interosseous muscle**: Adducts the digits toward the axial line. Assists the lumbrical muscles in extending the interphalangeal joints and flexing the metacarpophalangeal joints.
- **4th dorsal interosseous muscle:** Abducts digits from the axial line. Acts with the lumbrical muscles to extend the interphalangeal joints and to flex the metacarpophalangeal joints.

Clinical Relevance: Myotendinous dysfunction in the vicinity of TH 3 may cause difficult or painful ring or little finger movement. Acupuncture, massage, and laser therapy may improve symptoms arising from degenerative joint disease or other causes of arthralgia and arthrosis of the 4th and 5th metacarpophalangeal joints. Physical medicine techniques such as these, including electroacupuncture, assist in ameliorating mechanical and neurologic dysfunction of the wrist and hand after central nervous system injury, often in accordance with measures to strengthen voluntary flexion and extension.

Pain at TH 3 may manifest from local or proximal trigger point pathology. A trigger point in the ring finger extensor near TH 9 typically refers pain along the TH trajectory through TH 3 and on toward TH 2, with pain also referred proximad to LI 11. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles can also refer pain to the distal TH line at TH 3 and TH 2. Because of the multiplicity of causes of perceived pain in this region, a complete myofascial palpation exam should elucidate myriad contributors to ulnar hand pain.

Grasping and releasing objects with the hand and fingers constitute key components of the activities of daily living. Several pathologies reduce manual dexterity and limit functional independence. Neuromodulation of motor dysfunction assists in the repair of these movements for patients following cerebrovascular accident.[4] In patients afflicted with this problem, palpate all muscles from the neck and back to the fingers. Pay close attention to restriction found in the intrinsic muscles of the hand, the extensor digitorum communis (common digital extensor), flexor pollicis longus, and thenar muscle group. Needle, stretch, massage, and laser the regions accordingly.

TH 3

Figure 10-5. The Chinese name for TH 3 means "Central Islet" interposed between TH 2 ("Humor Gate") and TH 4 ("Yang Pool") maintains the reference to bodily fluid. This point sits in a shallow depression just proximal to the web space between the 4th and 5th metacarpophalangeal joints, made visible with a clenched fist. TH 2, in conjunction with the metacarpophalangeal joints of the 4th and 5th digits, form the angles of an equilateral triangle.

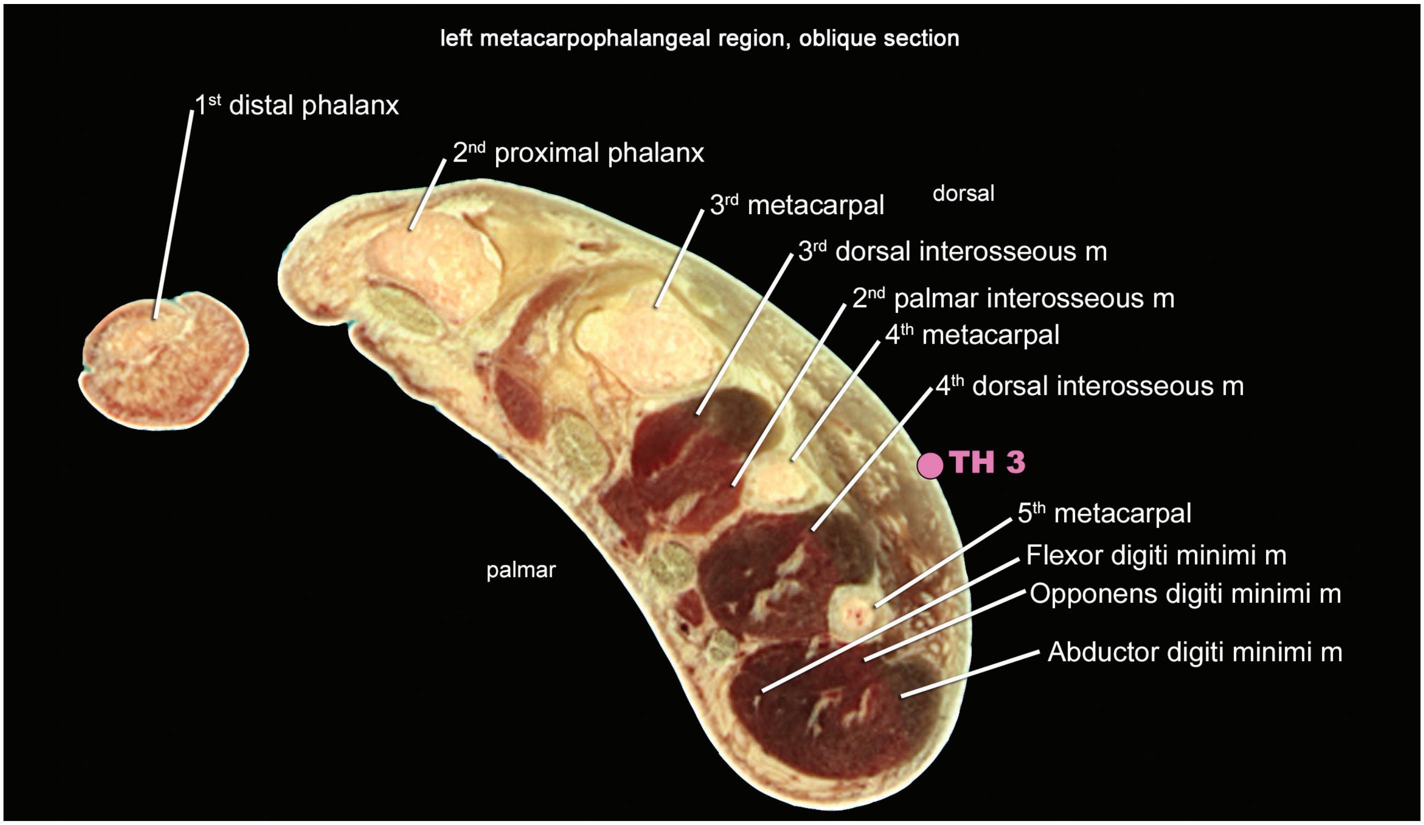

Figure 10-6. Trigger points in the 4th dorsal interosseous muscle appearing here deep to TH 3 may account for local and/or radiating pain to the digit. A trigger point in the ring finger extensor portion of the extensor digitorum muscle (at about LI 10 or TH 9) issues pain toward or through this site on its way to TH 2 and the ring finger.

Nerves

- **Common palmar digital branches of the superficial branch of the ulnar nerve:** Supply sympathetic motor innervation to the palmar and dorsal skin of the little finger and ulnar half of the ring finger.
- **Dorsal digital nerves:** Supplies the ulnar aspect of the ring finger, derived from the ulnar nerve.
- **Ulnar nerve (C8-T1):** The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, and the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: Needling of TH 3 produces an increase in sympathetic nervous system activity, given its rich afferent sensory supply.[5] This serves to awaken the brain to its presence in the hand, thereby facilitating communication between the central nervous system and the distal extremity, which would aid in the recovery of hand function in patients following brain or spinal cord injury. In addition, neuromodulation of the sensory and motor nerves supplying the extensors of the hand should improve coordination and proprioception for patients with myofascial dysfunction following trauma or overuse.

Vessels

- **Dorsal metacarpal artery:** Arises from the dorsal carpal arch and receives contributions from the superficial palmar arch via perforating branches.
- **Dorsal digital arteries:** The dorsal metacarpal artery divides into two dorsal digital arteries at the metacarpophalangeal region.
- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.

Clinical Relevance: Acupuncture and related techniques implemented along the distal TH line may improve circulation for patients with peripheral vascular disease affecting ring or little finger mobility and/or tissue health.

Indications and Potential Point Combinations

- **Temporal headache:** TH 3, GB 34, GB 21, local headache trigger points.

- **Sudden deafness:**[1,6] TH 3, GB 2, TH 17, LI 4, and GB 43.
- **Tinnitus:** Assess for upper cervical and temporomandibular somatic dysfunction and treat accordingly. TH 3, TH 21, SI 19, Taiyang.
- **Pain in elbow and upper arm:** TH 3; check for trigger points in the ring finger extensor portion of the extensor digitorum muscle and treat accordingly (TH 9, LI 10 vicinity)
- **Paralysis of upper extremities:** TH 3, Bafeng (web space) points, PC 8, PC 6, LI 4, identify interrupted source of neural input and treat accordingly (e.g., affected spinal cord segments and peripheral nerves).
- **Post-stroke hand dysfunction:**[7] TH 3, TH 5
- **Pain in neck and shoulders:** TH 3,TH 5, GB 21, GB 20, BL 10.
- **Central vestibular disorder:** TH 3, GB 34, ST 36.[8]

Evidence-Based Applications

- Acupuncture stimulation of TH 3 excited cortices of the bilateral frontal and temporal lobes, the cerebellum, and occipital lobes, affecting **areas of the brain that process acoustic, visual, and somatomotor function.**[2]
- Electroacupuncture at GB 2, TH 17, LI 4, GB 43, and TH 3 significantly improved hearing in patients with **sudden deafness** with better results than medication.[3]

TH 4

Yang Chi "Yang Pool"

On the dorsum of the wrist, at the junction of the ulna and carpal bones, in a depression between the tendons of the extensor digitorum and the extensor digiti minimi muscles. TH 4 can be found by starting at TH 3 and following the groove between the 4th and 5th metacarpal bones to the depression at the wrist. Ask the patient to move the digits in extension as though playing a piano while palpating to differentiate between the ring and little finger extensor tendons.

Connective Tissues

- **Dorsal radiocarpal ligament:** Originates from the dorsal margin of the distal radius. Extends in distal and oblique direction toward the ulnar aspect of the wrist. Fibers attach to the lunate bone and lunotriquetral interosseous ligament. The dorsal radiocarpal ligament and dorsal intercarpal ligaments form a "V" configuration. They function in alliance as a dorsal radioscaphoid ligament that varies its length by means of changing the angle of the "V".[3] The lateral "V" configuration allows normal carpal kinematic activity while, at the same time, stabilizing the dorsum of the wrist by means of its attachment to the scaphoid through wrist range of motion.4 The dorsal radiocarpal and intercarpal ligaments increases in length and tension with ulnar flexion of the wrist, as observed during a dart-throwing motion. Note the relative positions of the carpal bones available for viewing in Figure 10-8.

Clinical Relevance: This ligament of the wrist joint strengthens the fibrous capsule of the wrist. Equally if not more importantly, mechanoreceptors supply signals about joint perturbations to the central nervous system. Studies on wrist ligament-muscular reactions reveal that early-onset responses may serve to protect the joint while later reflexes may follow supraspinal reactions issued to stabilize the wrist joint.[1] This supraspinal control appears to involve dynamic fine-tuning of the corticospinal system during motor preparation in consideration of regulating afferent and efferent neural traffic.[2]

Tears, elongation, or strains of the dorsal radiocarpal ligament may negatively impact wrist stabilization and pronation. Laser therapy may aid in the restoration of ligamentous support on the dorsum of the wrist. It has shown value for problems associated with treatment of the transverse carpal ligament on the flexor surface.[5] While the latter application likely involved pain and functional changes related to neurovascular elements, laser therapy has shown value in improving connective tissue health related to ligaments of the knee.[6]

Tendons

- **Extensor digitorum tendon:** The chief extensor of the medial four digits. Extends the digits at the metacarpophalangeal joints and extends the hand at the wrist.
- **Extensor digiti minimi tendon:** Extends the little finger at both the metacarpophalangeal and interphalangeal joints.

Clinical Relevance: Myotendinous dysfunction in the vicinity of TH 4 may cause limited ring or little finger extension.

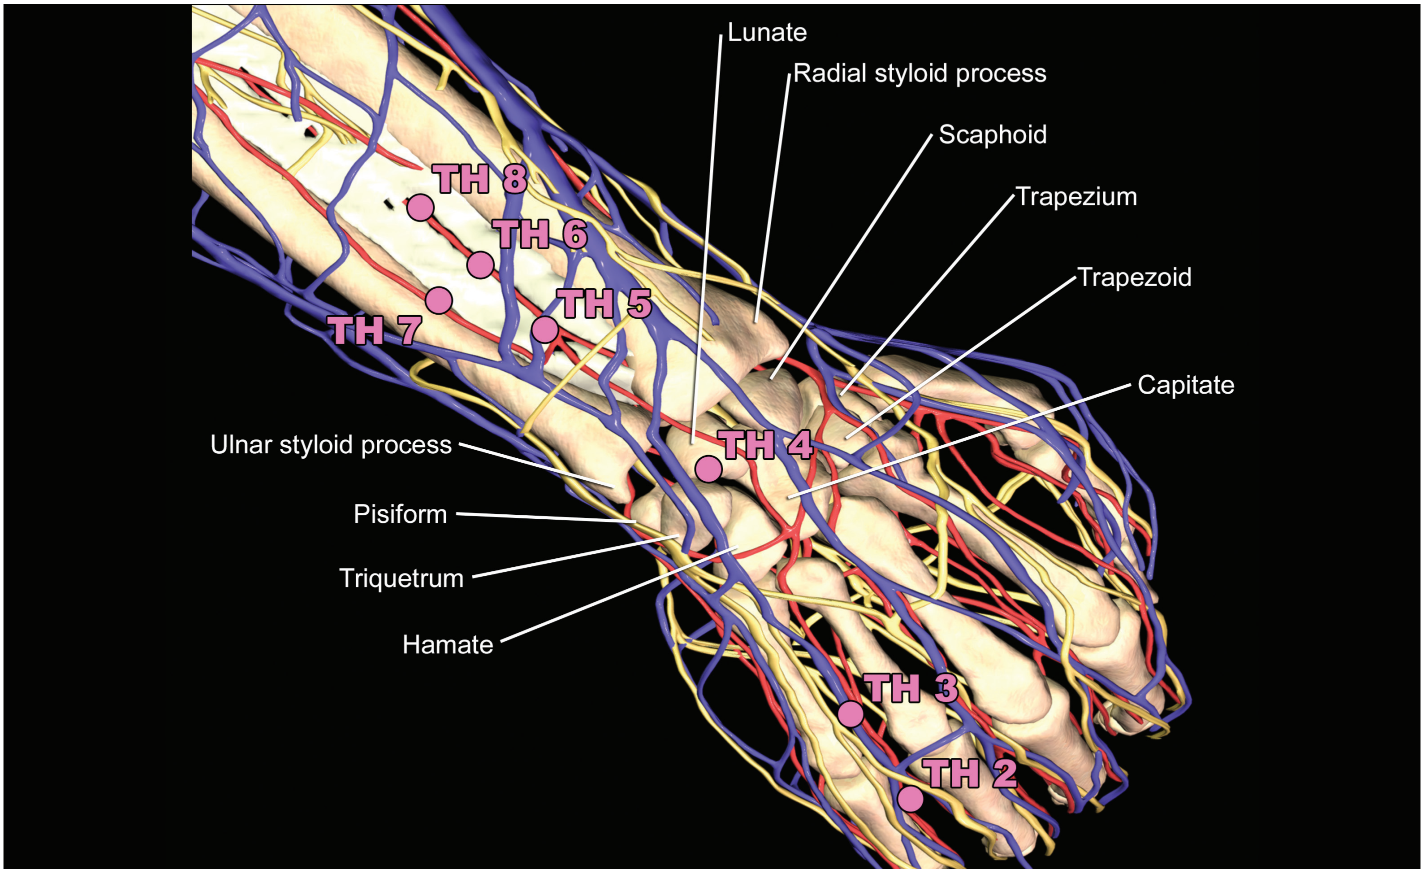

Figure 10-8. The depression forming the "Yang Pool" of TH 4 constitutes a cleft between the lunate and triquetral bones and the two diverging tendons. This pool occurs on the dorsum of the wrist, considered the "Yang" surface in Chinese medicine.

Acupuncture, massage, and laser therapy may improve symptoms arising from degenerative joint disease or other causes of arthralgia and arthrosis of the 4th and 5th metacarpophalangeal joints. Physical medicine techniques such as these, including electroacupuncture, assist in ameliorating mechanical and neurologic dysfunction of the wrist and hand after central nervous system injury, often in accordance with measures to strengthen voluntary flexion and extension.

Pain at TH 4 may manifest from local or proximal trigger point pathology. A trigger point in the ring finger extensor near TH 9 typically refers pain along the TH trajectory through TH 4 and on toward TH 2, with pain also referred proximad to LI 11. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles can also refer pain to the distal TH line at TH 4. Because of the multiplicity of causes of perceived pain in this region, a complete myofascial palpation exam should elucidate myriad contributors to ulnar hand pain.

Grasping and releasing objects with the hand and fingers constitute key components of the activities of daily living. Several pathologies reduce manual dexterity and limit functional independence. Neuromodulation of motor dysfunction assists in the repair of these movements for patients following cerebrovascular accident.[7] In patients afflicted with this problem, palpate all muscles from the neck and back to the fingers. Pay close attention to restriction found in the intrinsic muscles of the hand, the extensor digitorum communis (common digital extensor), flexor pollicis longus, and thenar muscle group. Needle, stretch, massage, and laser the regions accordingly.

The term "trigger finger" ("stenosing tenosynovitis") ordinarily applies to flexor tendon triggering, confirmed by finding a sudden extension of the involved finger at the proximal interphalangeal joint when the flexor tendon passes through the A1, or first annular, pulley near the head of the metacarpal bone. This leads to a palpable "triggering" or snap on the palmar aspect of the metacarpophalangeal joint. The extensor digiti minimi may develop a trigger phenomenon as well, manifesting as painful radial subluxation of the tendon over the metacarpal head. Some patients report hearing a "click" and feeling pain at the site of the 5th extensor retinaculum in conjunction with finger flexion.[8] The site of the snapping occurs just ulnar to TH 2 and TH 3 (at the metacarpophalangeal joint). While release of the extensor retinaculum constitutes one approach, physical medicine measures involving acupuncture and related techniques offer an alternative, conservative, intervention that may obviate more invasive interventions.

Nerves

- **Ulnar nerve (C8-T1):** The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, and the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.

- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus, extensor indicis, extensor digitorum, extensor digiti minimi, and extensor carpi ulnaris muscles.

Clinical Relevance: Fractures of the thoracic limb can injure peripheral nerves. Radial neck fracture may lead to injuries of the posterior interosseous and ulnar nerves.[9] Displacement of bone after high-energy trauma induces nerve traction with acute deficits. Iatrogenic entrapment following fracture reduction places compressive forces on nerves. Conservative management that includes acupuncture, massage, and/or laser therapy addresses neuropathic pain and functional restoration.

The posterior interosseous nerve passes deep to the arcade of Frohse, otherwise known as the supinator arch. This superficial layer of the supinator muscle may entrapment the posterior interosseous nerve by means of Schwannoma, or through extrinsic compression with fibrous brands, ganglion cysts, fractures, etc.[10]

Deep needling of TH points distal to the elbow risks injuring the posterior interosseous nerve, which can cause progressive wrist drop. The posterior interosseous nerve supplies wrist and digital extensors. Mechanisms of neurotrauma secondary to acupuncture include compressive neuropathy following surrounding hematoma, irritation by a fractured needle tip, or laceration of the nerve through vigorous, deep needling.[11]

Vessels

- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.

- **Dorsal carpal branch of the ulnar artery:** Arises from the ulnar artery at the wrist. Anastomoses with branches of the radial artery, thereby providing collateral circulation for the wrist joint via dorsal and palmar carpal arches.

- **Posterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The posterior interosseous artery gives rise to the recurrent interosseous artery, which participates in the anastomoses around the elbow joint.

- **Anterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The anterior interosseous artery supplies both sides of the interosseous membrane by providing a dorsal branch that courses along the distal posterior portion of the interosseous membrane.

- **Posterior interosseous vein:** These deep veins accompany the interosseous arteries. The drain into the veins accompanying the radial and ulnar arteries.

Clinical Relevance: Acupuncture and related techniques implemented along the distal TH line may improve circulation for patients with peripheral vascular disease affecting ring or little finger mobility and/or tissue health.

Hematomata or aneurysms of vessels in the extensor surface groove between radius and ulna may compress the posterior interosseous nerve.[12]

Indications and Potential Point Combinations

- **Pain in wrist:** Identify source of pain (arthrodial, referred myofascial, neuropathic, etc.) For pain on the dorsal wrist, TH 4, TH 5, and trigger points responsible for referred pain, if present. These triggers may include TH 9/LI 10 region over the middle and ring finger extensors or a trigger point in the extensor indicis muscle at TH 5 that strongly refers pain to the central dorsal wrist.

- **Arm or shoulder pain:** Trigger points in the long head of the triceps muscle may refer pain to the wrist near TH 4. Palpate for trigger points in the triceps; consider TH 11, TH 12.

- **Tonsillitis, pharyngitis:** TH 4, TH 21, CV 23, CV 22.

- **Trigger finger:** LI 11, LI 10, LI 4, TH 5, TH 4.[13]

Evidence-Based Applications

- Treatment of **"snapping" finger** was addressed by bilateral acupuncture at TH 4, TH 5, LI 4, LI 10, and LI 11.[14]

- The "up-down cross" method of stimulating the contralateral opposite limb calls for TH 4 for the treatment of **ankle sprain.**[15,16] According to this approach, PC 7 qualifies as an alternate point for the treatment of ankle sprain and instability. See Figure 10-9 to identify their relationship to one another at the wrist.

- Thoracic limb spasticity following **stroke** with TH 4, TH 10, LI 15, PC 7, LU 5, and HT 1, along with contralateral scalp acupuncture.[17]

TH 5

Wai Guan "Outer Pass"

On the dorsal distal antebrachium, 2 cun proximal to the dorsal wrist crease and TH 4, on the line connecting TH 4 and the tip of the olecranon.

Connective Tissues

- **Interosseous membrane between the radius and ulna:** Binds the two bones of the forearm. Allows load on the forearm to distribute between the radius and ulna. The interosseous membrane is a complex structure consisting of a central band, proximal interosseous band, membranous portions, and accessory bands. The central portion of the interosseous membrane possesses the most strength, considered by some tantamount in strength to the anterior cruciate ligament or patellar tendon. The anterior interosseous vessels and nerve supply the PC (volar) surface of the membrane; the posterior interosseous counterparts supply the TH (dorsal) surface, in conjunction with a dorsal branch of the anterior interosseous vessels.

The interosseous membrane provides longitudinal stability to the forearm.[11] The forearm acts as a joint with the interosseous membrane serving as the ligamentous connection.[12] The forearm complex, or joint, supports forearm function; rotation of the radius around the ulna is required for activities of daily living such as eating and maintaining personal hygiene.[13]

Clinical Relevance: High-force compressive trauma can injure the forearm and elbow, tearing the membrane, fracturing the radial head, and causing failure of the triangular fibrocartilage complex. Instability of the forearm leads to considerable pain and debility by limiting antebrachial motion and disturbing the biomechanics of the wrist.[14] One injury pattern that precipitates forearm instability involves axial load transmitted through the wrist to the elbow. The diagnosis is often overlooked; early recognition and effective care improve outcomes, as only a fifth of patients with delayed intervention experience satisfactory recovery.[15] Whether or not patients pursue surgery, restoring soft tissue stability remains a critical component in the treatment of chronic radioulnar dissociation injury. Nonsurgical means of improving tissue health and proprioception include acupuncture and related techniques. Laser therapy fosters tissue healing. Massage lessens myofascial restriction and improves proprioception and circulation, as does acupuncture.

Muscles and Tendons

- **Extensor digitorum tendon:** The chief extensor of the medial four digits. Extends the digits at the metacarpophalangeal joints and extends the hand at the wrist.
- **Extensor digiti minimi tendon:** Extends the little finger at both the metacarpophalangeal and interphalangeal joints.
- **Extensor indicis muscle:** Extends the index finger. Helps extend the entire hand.
- **Extensor pollicis longus muscle:** Extends the proximal phalanx of the thumb at the carpometacarpal joint.

Clinical Relevance: Myotendinous dysfunction in the vicinity of TH 5 may cause limited ring or little finger extension.

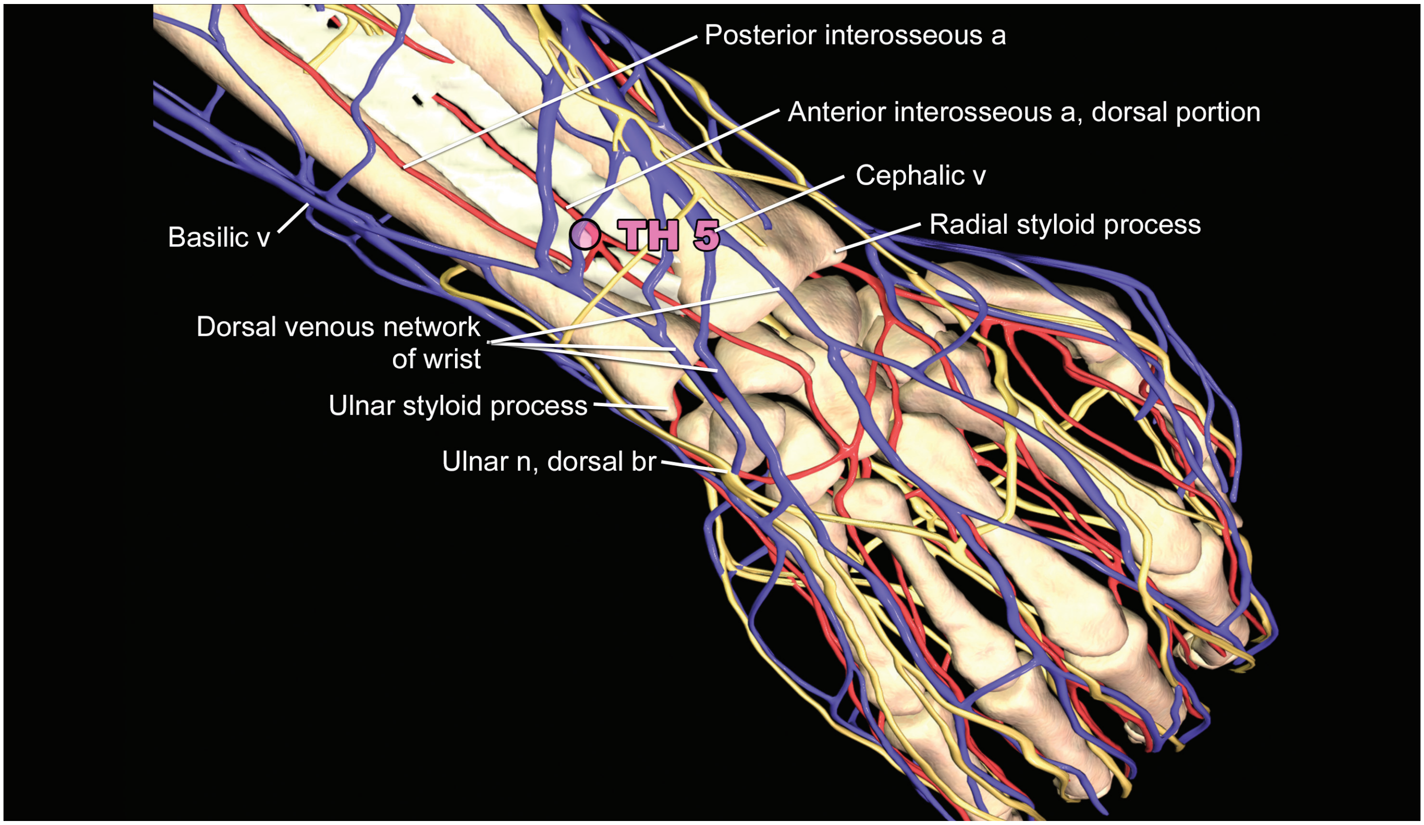

Figure 10-10. TH 5, the "Outer Pass" supplies the dorsal, or Yang, surface of the distal antebrachium, serving as an "outer" counterpart to PC 6, called the "Inner Pass". Both relate anatomically to the passage of the anterior interosseous vessels from the volar to the dorsal surface. This vascular link between the TH and PC lines explains its status as a "Luo", or "connecting" point in Chinese medicine.

Figure 10-11. The analgesic effects of TH 5 stimulation for patients with wrist pain stems at least in part from its relationship to the trigger point in the extensor indicis muscle, shown here. The referred pain pattern from a trigger point at TH 5 in the extensor indicis muscle extends from TH 4 toward LI 4, LI 3, and LI 2. The overlap in pain patterns from myriad trigger points in the thoracic limb involving TH and LI points arises from the fact that both receive innervation from the radial nerve.

Acupuncture, massage, and laser therapy may improve symptoms arising from degenerative joint disease or other causes of arthralgia and arthrosis of the 4th and 5th metacarpophalangeal joints. Physical medicine techniques such as these, including electroacupuncture, assist in ameliorating mechanical and neurologic dysfunction of the wrist and hand after central nervous system injury, often in accordance with measures to strengthen voluntary flexion and extension.

Pain at TH 5 may manifest from local or proximal trigger point pathology. A trigger point in the ring finger extensor near TH 9 typically refers pain along the TH trajectory through TH 5 and on toward TH 2, with pain also referred proximad to LI 11. Trigger points in the middle finger extensor describe a line of referred pain along the TH channel too, but head toward the middle, rather than ring, finger. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles can also refer pain to the distal TH line near TH 5. A trigger point in the extensor indicis muscle, beneath TH 5 and TH 6, issues pain in the direction of LI 2, LI 3, and LI 4. Note the abundant myotendinous junctions located at the level of the antebrachium that house TH 5 and TH 6. These sites supply the tissue with Golgi tendon organs, affording opportunities to neuromodulate mechanoreceptors and adjust proprioceptive “set points” governing motor control. Several myofascial sources can cause pain in this region, thus making a complete myofascial palpation exam vital in order to identify contributors to distal thoracic limb discomfort.

Grasping and releasing objects with the hand and fingers constitute key components of the activities of daily living. Several pathologies reduce manual dexterity and limit functional independence. Neuromodulation of motor dysfunction assists in the repair of these movements for patients following cerebrovascular accident.[16] In patients afflicted with this problem, palpate all muscles from the neck and back to the fingers. Pay close attention to restriction found in the intrinsic muscles of the hand, the extensor digitorum communis (common digital extensor), flexor pollicis longus, and thenar muscle group. Needle, stretch, massage, and laser the regions accordingly.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus, extensor indicis, extensor digitorum, extensor digiti minimi, and extensor carpi ulnaris muscles.

Clinical Relevance: Fractures of the thoracic limb can injure peripheral nerves. Radial neck fracture may lead to injuries of the posterior interosseous and ulnar nerves.[17] Displacement of bone after high-energy trauma places traction on the nerve. Iatrogenic entrapment following fracture reduction can compress the nerves. Conservative management that includes acupuncture, massage, and/or laser therapy addresses neuropathic pain and aids in functional restoration.

The posterior interosseous nerve passes deep to the arcade of Frohse, otherwise known as the supinator arch. This superficial layer of the supinator muscle may entrapment the posterior interosseous nerve by means of Schwannoma, or through extrinsic compression with fibrous brands, ganglion cysts, fractures, etc.[18]

Deep needling of TH points distal to the elbow risks injuring the posterior interosseous nerve, which can cause progressive wrist drop. The posterior interosseous nerve supplies wrist and digital extensors. Mechanisms of neurotrauma secondary to acupuncture include compressive neuropathy following surrounding hematoma, irritation by a fractured needle tip, or laceration of the nerve through vigorous, deep needling.[19]

Vessels

- **Posterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The posterior interosseous artery gives rise to the recurrent interosseous artery, which participates in the anastomoses around the elbow joint.
- **Anterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The anterior interosseous artery supplies both sides of the interosseous membrane by providing a dorsal branch that courses along the distal posterior portion of the interosseous membrane.
- **Posterior interosseous vein:** These deep veins accompany the interosseous arteries. The drain into the veins accompanying the radial and ulnar arteries.

Clinical Relevance: Acupuncture and related techniques implemented along the distal TH line may improve circulation for patients with peripheral vascular disease affecting ring or little finger mobility and/or tissue health. Blood flow changes in nail-fold microcirculation following acupuncture at TH 5 involve spinal cord reflexes in related spinal segments.[20]

Hematomata or aneurysms of vessels in the extensor surface groove between radius and ulna may compress the posterior interosseous nerve.[21]

Indications and Potential Point Combinations

- **Myofascial restriction in the elbow, forearm, or wrist:** Check for trigger points in the ring finger extensor portion of the extensor digitorum muscle. Such triggers radiate pain to the elbow at LI 11, LI 10/TH 9, and distal along the TH line, including TH 5. Needle accordingly.
- **Shoulder problems:** Trigger points in the long head of the triceps brachii muscle radiate proximal to the shoulder region at TH 14 and then toward the neck near GB 21. The distal radiation pattern proceeds along the posterior/caudal brachium along the TH line to TH 10. It continues along the TH line toward TH 5 and TH4. Needle according to the trigger point and pain patterns.
- **Occipital headaches migrating to the forehead and eyes:** TH 5, TH 16, BL 10, BL 2, Taiyang.
- **Problems in the ear, nose, or throat:** TH 5, LI 4, GV 20, and local points for the ear (TH 21, TH 20), the nose (LI 20), and throat (CV 23).
- **Trigger finger:** LI 11, LI 10, LI 4, TH 5, TH 4.[22]

Evidence-Based Applications

- Both laser and needle acupuncture at GB 1, BL 2, ST 5, Yintang, LI 4, SI 3, LR 3, KI 6, and TH 5 worked equally well in improving objective measurements of **keratoconjunctivitis sicca (KCS).**[1]
- A case series involving acupuncture at LI 4, TH 5, LR 3, ST 36, ST 7, ST 6, and SI 17, splint therapy, and point injection therapy suggested that this combination was effective for managing **temporomandibular disorders.**[2]
- Electroacupuncture (at ST 29 and TH 5 to LI 4) with manual acupuncture at GV 20 and ST 36 serve as an **effective analgesic during oocyte aspiration;** these analgesic effects equal those of conventional analgesics.[3] Neuropeptide Y (NPY) concentrations in follicular fluid were higher in the electroacupuncture group than in the medication group; NPY may be important for human ovarian steroidogenesis.[4]
- Electroacupuncture (at BL 23, BL 28, SP 6, and SP 9) in combi nation with manual acupuncture (at PC 6, TH 5, and GV 20) induced regular ovulations in some women with **polycystic ovary syndrome,** thereby offering an alternative to pharmacologic induction of ovulation.[5]
- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[6]
- Acupuncture at SI 3, SI 14, LR 3, BL 10, BL 60, GB 20, GB 34, TH 5, trapezius myofascial trigger point, and the auricular point "cervical spine" provided greater pain relief of **chronic neck pain** compared to massage, but not sham laser.[7]
- Acupuncture at LI 4, LI 10, LI 11, LI 15, and TH 5 alleviated pain and improved function in patients with **chronic lateral epicondylitis (tennis elbow).**[8]
- Needling TH 5 alone or in combination with GB 34 produced a concentrated activation of the **bilateral frontal and parietal lobes** of the brain based on fMRI evaluation.[9]
- Acupuncture at TH 5, GB 34, and GB 20 outperformed control acupuncture at ST 8, ST 36, and LI 6 for patients with **migraine.**[23] The former point grouping produced higher brain metabolism in the middle temporal cortex, the orbital frontal cortex, the insula, middle frontal gyrus, angular gyrus, post-cingulate cortex, precuneus, and middle cingulate cortex than that exhibited by migraineurs without acupuncture treatment.
- Acupuncture at TH 5 aids in the recovery of patients following **cerebrovascular accident,** or stroke, perhaps in part by regulating areas of the brain related to motor execution and vision.[24]
- Acupuncture at TH 5 and LI 11 affected subjective pain intensity on a numerical pain rating scale as well as endplate noise recorded from **myofascial trigger points in the upper trapezius**

Figure 10-12. This cross-section portrays illustrates the dorsal-volar relationship of TH 5 and PC 6. Some practitioners have been known to stimulate both points with one long needle that enters PC 6 and tents the skin beneath TH 5. Such aggressive treatment may injure underlying vessels and/or nerves.

muscle, demonstrating the remote influence of acupuncture on trigger points.[10]

- Treatment of **“snapping” finger** was addressed by bilateral acupuncture at TH 4, TH 5, LI 4, LI 10, and LI 11.[25]
- Electroacupuncture in conjunction with general anesthesia **accelerated post-operative anesthetic recovery** after craniotomy, utilizing the following points connected to the electrical stimulator: TH 5, LI 4, ST 36, BL 63, LR 3, and GB 40.[26]
- Electrical stimulation of nerves and muscle involving local facial points as well as TH 5, LI 4, SP 6, and LR 3 accelerates recovery from **facial nerve injury.**[27]
- Weight loss in **obese patients elevated temperature** at TH 5 and LI 4.[28]
- Acupuncture at TH 5 appears to **balance autonomic tone** by means of changes in associated spinal cord segments.[29]

TH 6

Zhi Gou "Branch Ditch"

On the dorsal distal antebrachium, 3 cun proximal to the dorsal wrist crease and TH 4, on the line connecting TH 4 and the tip of the olecranon. Between the radius and the extensor digitorum muscle, close to the radius, 1/4 the distance from TH 4 to the lateral epicondyle of the humerus.

Connective Tissues

- **Interosseous membrane between the radius and ulna:** Binds the two bones of the forearm. Allows load on the forearm to distribute between the radius and ulna. The interosseous membrane is a complex structure consisting of a central band, proximal interosseous band, membranous portions, and accessory bands. The central portion of the interosseous membrane possesses the most strength, considered by some tantamount in strength to the anterior cruciate ligament or patellar tendon. The anterior interosseous vessels and nerve supply the PC (volar) surface of the membrane; the posterior interosseous counterparts supply the TH (dorsal) surface, in conjunction with a dorsal branch of the anterior interosseous vessels.

The interosseous membrane provides longitudinal stability to the forearm.[4] The forearm acts as a joint with the interosseous membrane serving as the ligamentous connection.[5] The forearm complex, or joint, supports forearm function; rotation of the radius around the ulna is required for activities of daily living such as eating and maintaining personal hygiene.[6]

Clinical Relevance: High-force compressive trauma can injure the forearm and elbow, tearing the membrane, fracturing the radial head, and causing failure of the triangular fibrocartilage complex. Instability of the forearm leads to considerable pain and debility by limiting antebrachial motion and disturbing the biomechanics of the wrist.[7] One injury pattern that precipitates forearm instability involves axial load transmitted through the wrist to the elbow. The diagnosis is often overlooked; early recognition and effective care improve outcomes, as only a fifth of patients with delayed intervention experience satisfactory recovery.[8] Whether or not patients pursue surgery, restoring soft tissue stability remains a critical component in the treatment of chronic radioulnar dissociation injury. Nonsurgical means of improving tissue health and proprioception include acupuncture and related techniques. Laser therapy fosters tissue healing. Massage lessens myofascial restriction and improves proprioception and circulation, as does acupuncture.

Muscles

- **Extensor digitorum muscle:** The chief extensor of the medial four digits. Extends the digits at the metacarpophalangeal joints and extends the hand at the wrist.
- **Extensor digiti minimi muscle:** Extends the little finger at both the metacarpophalangeal and interphalangeal joints.

Extensor pollicis brevis tendon
TH 6
TH 5
Extensor pollicis longus m

Figure 10-13. Like TH 5, TH 6 deactivates myofascial trigger points palpated nearby, such as within the extensor indicis muscle. Other trigger points typically refer pain along the TH trajectory. For example, a trigger point in the extensor carpi radialis brevis muscle, near LI 8 and LI 9 region sends a pain referral pattern to the dorsum of the wrist along the TH channel. In addition, a trigger point in the ring finger extensor radiates pain to the ring finger from the vicinity of TH 9.

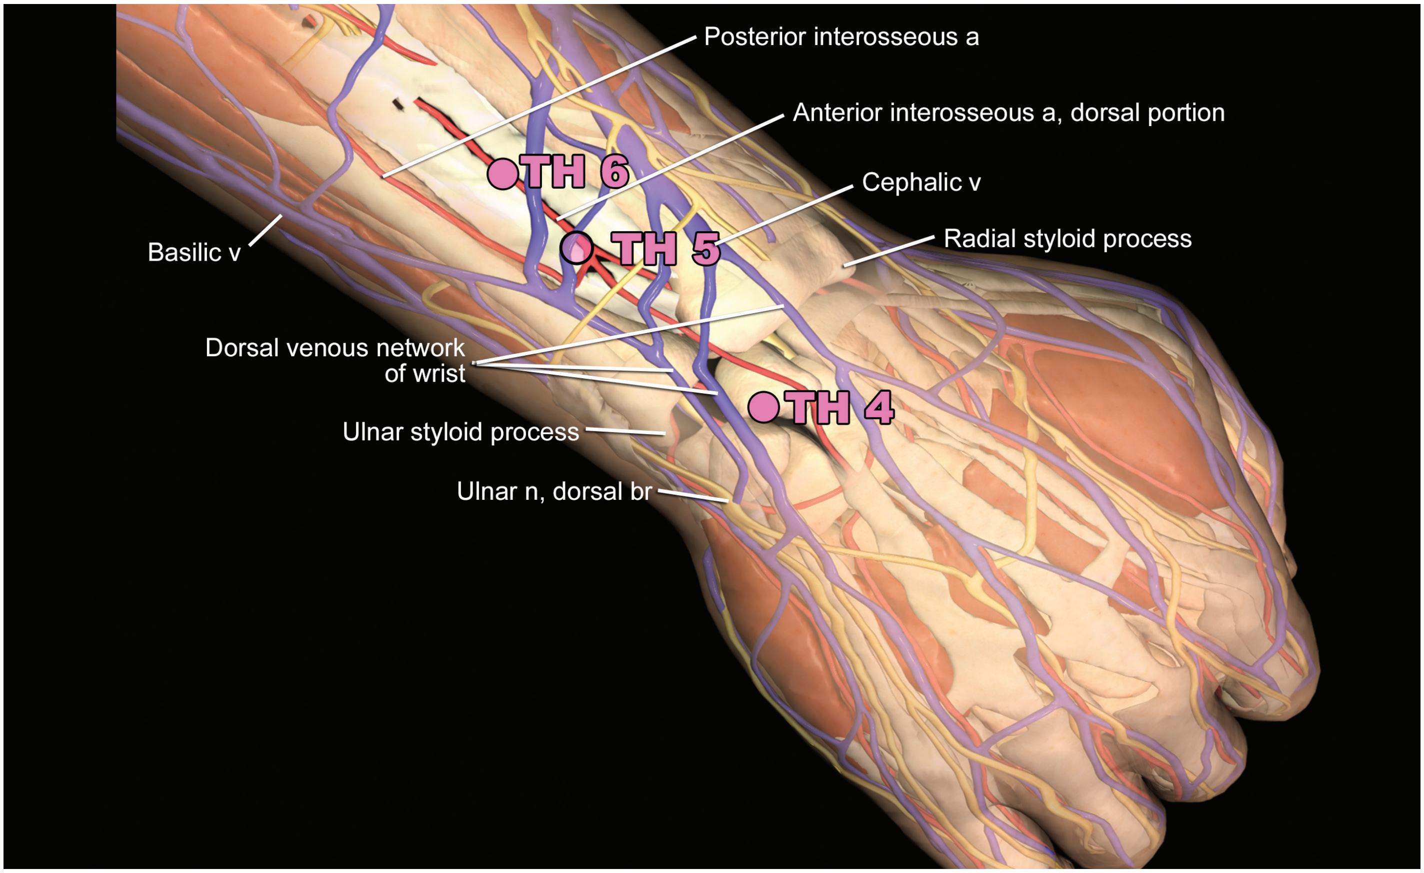

Figure 10-14. The descriptive name for TH 6, "Branch Ditch", connotes a deep waterway extending off of a main channel. The name pertains to the dorsal branch of the anterior interosseous artery that pierces the interosseous membrane, thus allowing it to supply the dorsal, as well as volar, surfaces.

- **Extensor indicis muscle:** Extends the index finger. Helps extend the entire hand.
- **Extensor pollicis longus muscle:** Extends the proximal phalanx of the thumb at the carpometacarpal joint.

Clinical Relevance: Myotendinous dysfunction in the vicinity of TH 6 may cause limited ring or little finger extension. Acupuncture, massage, and laser therapy may improve symptoms arising from degenerative joint disease or other causes of arthralgia and arthrosis of the 4th and 5th metacarpophalangeal joints. Physical medicine techniques such as these, including electroacupuncture, assist in ameliorating mechanical and neurologic dysfunction of the wrist and hand after central nervous system injury, often in accordance with measures to strengthen voluntary flexion and extension.

Pain at TH 6 may manifest from local or proximal trigger point pathology. A trigger point in the extensor indicis muscle, beneath TH 5 and TH 6, issues pain in the direction of LI 2, LI 3, and LI 4. A trigger point in the ring finger extensor near TH 9 typically refers pain along the TH trajectory through TH 6 and on toward TH 2, with pain also referred proximad to LI 11. Trigger points in the middle finger extensor describe a line of referred pain along the TH channel too, but head toward the middle, rather than ring, finger. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles can also refer pain to the distal TH line.

Note the abundant myotendinous junctions available for activation at the level of the TH 5 and TH 6. The myotendinous junctions house Golgi tendon organs, affording opportunities to neuromodulate mechanoreceptors and adjust proprioceptive "set points" governing motor control. Several myofascial sources can cause pain in this region, thus making a complete myofascial palpation exam vital in order to identify contributors to distal thoracic limb discomfort.

Grasping and releasing objects with the hand and fingers constitute key components of the activities of daily living. Several pathologies reduce manual dexterity and limit functional independence. Neuromodulation of motor dysfunction assists in the repair of these movements for patients following cerebrovascular accident.[9] In patients afflicted with this problem, palpate all muscles from the neck and back to the fingers. Pay close attention to restriction found in the intrinsic muscles of the hand, the extensor digitorum communis (common digital extensor), flexor pollicis longus, and thenar muscle group. Needle, stretch, massage, and laser the regions accordingly.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus, extensor indicis, extensor digitorum, extensor digiti minimi, and extensor carpi ulnaris muscles. Also supplies the posterior surface of the interosseous membrane.

Clinical Relevance: Fractures of the thoracic limb can injure

peripheral nerves. Radial neck fracture may lead to injuries of the posterior interosseous and ulnar nerves.[10] Displacement of bone after high-energy trauma places traction on the nerve. Iatrogenic entrapment following fracture reduction can compress the nerves. Conservative management that includes acupuncture, massage, and/or laser therapy addresses neuropathic pain and aids in functional restoration.

The posterior interosseous nerve passes deep to the arcade of Frohse, otherwise known as the supinator arch. This superficial layer of the supinator muscle may entrapment the posterior interosseous nerve by means of Schwannoma, or through extrinsic compression with fibrous brands, ganglion cysts, fractures, etc.[11]

Deep needling of TH points distal to the elbow risks injuring the posterior interosseous nerve, which can cause progressive wrist drop. The posterior interosseous nerve supplies wrist and digital extensors. Mechanisms of neurotrauma secondary to acupuncture include compressive neuropathy following surrounding hematoma, irritation by a fractured needle tip, or laceration of the nerve through vigorous, deep needling.[12]

Vessels

- **Anterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The anterior interosseous artery supplies both sides of the interosseous membrane by providing a dorsal branch that courses along the distal posterior portion of the interosseous membrane.
- **Posterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The posterior interosseous artery gives rise to the recurrent interosseous artery, which participates in the anastomoses around the elbow joint.
- **Posterior interosseous vein:** These deep veins accompany the interosseous arteries. The drain into the veins accompanying the radial and ulnar arteries.

Clinical Relevance: Acupuncture and related techniques implemented along the distal TH line may improve circulation for patients with peripheral vascular disease affecting ring or little finger mobility and/or tissue health. Blood flow changes in nail-fold microcirculation following acupuncture at TH 5 and, likely, TH 6 involve spinal cord reflexes in related spinal segments.[13]

Hematomata or aneurysms of vessels in the extensor surface groove between radius and ulna may compress the posterior interosseous nerve.[14]

Indications and Potential Point Combinations

- **Myofascial restriction in the elbow, forearm, or wrist:** Check for trigger points in the ring finger extensor portion of the extensor digitorum muscle. Such triggers radiate pain to the elbow at LI 11, LI 10/TH 9, and distal along the TH line, including TH 5. Needle accordingly.
- **Constipation:** TH 6, ST 36, BL 32; or TH 6, ST 36, SP 6, and LI 4.[15]

Evidence-Based Application

- Acupuncture at BL 32, TH 6, and ST 36 improved **constipation due to diabetes mellitus** in a report on a series of cases.[1]
- Electroacupuncture at TH 6 improved colonic transit and reduced symptoms of **constipation.**[2]
- Electroacupuncture from ST 36 to SP 6 and LI 4 to TH 6 reduced the duration of postoperative ileus, time to ambulation, the requirements for **postoperative analgesia following laparoscopic surgery for colorectal cancer.**[16]
- Electroacupuncture of Jiaji points, focus-encircled needling ("circle the dragon"), TH 6, and SI 3 outperformed medication in speeding crust formation and providing analgesia for patients with **herpes zoster.**[3]

TH 7

Hui Zong "Ancestral Meeting" or "Converging and Gathering"

On the dorsal distal antebrachium, 3 cun proximal to the dorsal wrist crease and TH 4, approximately 1 fingerbreadth to the ulnar side of TH 6, on the radial border of the ulna.

In the depression between the ulna and the extensor digiti minimi, 1/4 the distance from the wrist to the lateral epicondyle of the humerus.

Connective Tissues

- **Interosseous membrane between the radius and ulna:** Binds the two bones of the forearm. Allows load on the forearm to distribute between the radius and ulna. The interosseous membrane is a complex structure consisting of a central band, proximal interosseous band, membranous portions, and accessory bands. The central portion of the interosseous membrane possesses the most strength, considered by some tantamount in strength to the anterior cruciate ligament or patellar tendon. The anterior interosseous vessels and nerve supply the PC (volar) surface of the membrane; the posterior interosseous counterparts supply the TH (dorsal) surface, in conjunction with a dorsal branch of the anterior interosseous vessels.

The interosseous membrane provides longitudinal stability to the forearm.[1] The forearm acts as a joint with the interosseous membrane serving as the ligamentous connection.[2] The forearm complex, or joint, supports forearm function; rotation of the radius around the ulna is required for activities of daily living such as eating and maintaining personal hygiene.[3]

Clinical Relevance: High-force compressive trauma can injure the forearm and elbow, tearing the membrane, fracturing the radial head, and causing failure of the triangular fibrocartilage complex. Instability of the forearm leads to considerable pain and debility by limiting antebrachial motion and disturbing the biomechanics of the wrist.[4] One injury pattern that precipitates forearm instability involves axial load transmitted through the wrist to the elbow. The diagnosis is often overlooked; early recognition and effective care improve outcomes, as only a fifth of patients with delayed intervention experience satisfactory recovery.[5] Whether or not patients pursue surgery, restoring soft tissue stability remains a critical component in the treatment of chronic radioulnar dissociation injury. Nonsurgical means of improving tissue health and proprioception include acupuncture and related techniques. Laser therapy fosters tissue healing. Massage lessens myofascial restriction and improves proprioception and circulation, as does acupuncture.

TH 6
TH 7
Extensor pollicis longus m

Figure 10-16. As the Xi-Cleft point, TH 7 resides at the myotendinous junction of the extensor indicis and extensor digiti minimi muscles, thereby offering opportunities for mechanoreceptor neuromodulation.

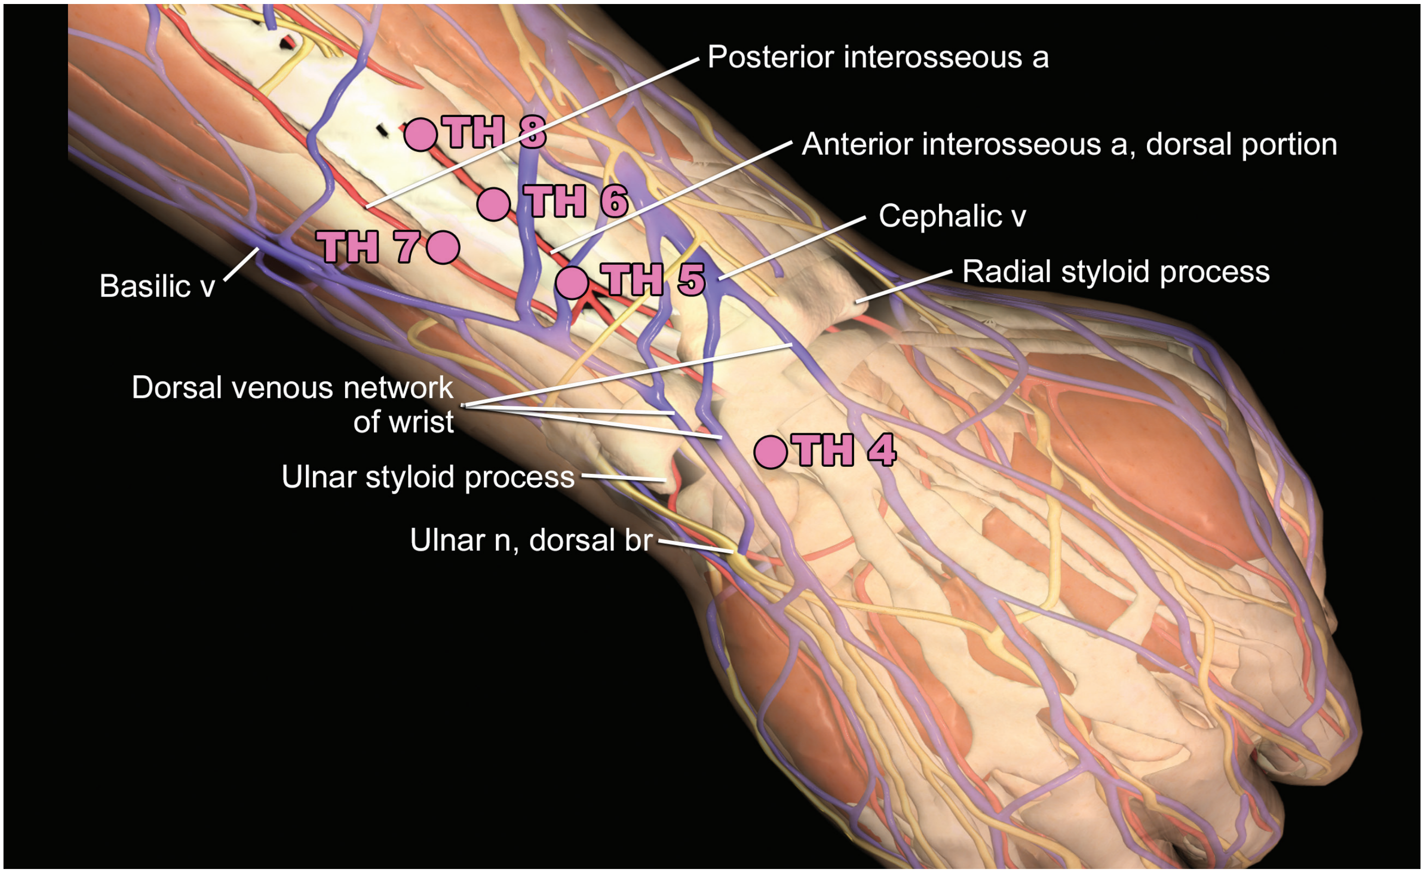

Figure 10-17. "Converging and Gathering" describes the behavior of the anterior and posterior interosseous arteries at TH 7. This image denotes how the location of TH 7 fits the parallel placement of posterior interosseous partner to the dorsal portion of the anterior interosseous artery.

Muscles

- **Extensor digitorum muscle:** The chief extensor of the medial four digits. Extends the digits at the metacarpophalangeal joints and extends the hand at the wrist.
- **Extensor digiti minimi muscle:** Extends the little finger at both the metacarpophalangeal and interphalangeal joints.
- **Extensor indicis muscle:** Extends the index finger. Helps extend the entire hand.
- **Extensor pollicis longus muscle:** Extends the proximal phalanx of the thumb at the carpometacarpal joint.
- **Extensor carpi ulnaris muscle:** Extends and adducts the hand at the wrist.

Clinical Relevance: Myotendinous dysfunction in the vicinity of TH 7 may limit or otherwise disturb function in the ring or little fingers. Acupuncture, massage, and laser therapy may improve symptoms arising from degenerative joint disease or other causes of arthralgia and arthrosis of the 4th and 5th metacarpophalangeal joints. Physical medicine techniques such as these, including electroacupuncture, assist in ameliorating mechanical and neurologic dysfunction of the wrist and hand after central nervous system injury, often in accordance with measures to strengthen voluntary flexion and extension.

Pain at TH 7 may manifest from local or proximal trigger point pathology. A trigger point in the extensor indicis muscle, beneath TH 7, issues pain in the direction of LI 2, LI 3, and LI 4. A trigger point in the ring finger extensor near TH 9 typically refers pain along the TH trajectory through TH 6 and on toward TH 2, with pain also referred proximad to LI 11. Trigger points in the middle finger extensor describe a line of referred pain along the TH channel too, but head toward the middle, rather than ring, finger. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles can also refer pain to the distal TH line.

Note the abundant myotendinous junctions available for activation at the level of the TH 7. The myotendinous junctions house Golgi tendon organs, affording opportunities to neuromodulate mechanoreceptors and adjust proprioceptive "set points" governing motor control. Several myofascial sources can cause pain in this region, thus making a complete myofascial palpation exam vital in order to identify contributors to distal thoracic limb discomfort.

Grasping and releasing objects with the hand and fingers constitute key components of the activities of daily living. Several pathologies reduce manual dexterity and limit functional independence. Neuromodulation of motor dysfunction assists in the repair of these movements for patients following cerebrovascular accident.[6] In patients afflicted with this problem, palpate all muscles from the neck and back to the fingers. Pay close attention to restriction found in the intrinsic muscles of the hand, the extensor digitorum communis (common digital extensor), flexor pollicis longus, and thenar muscle group. Needle, stretch, massage, and laser the regions accordingly.

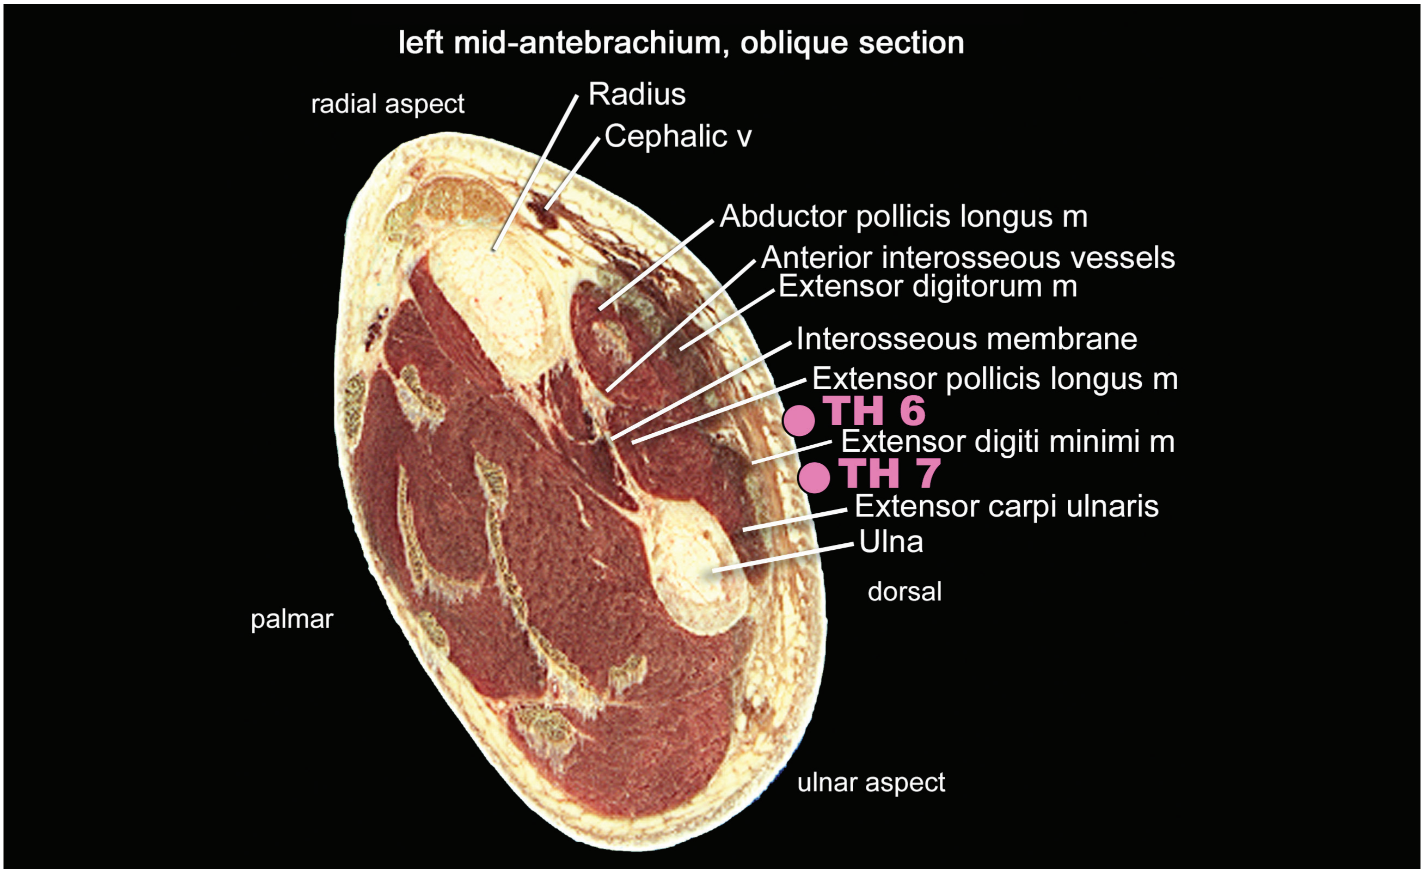

Figure 10-18. This cross-section presents the muscles and tendons within reach of an acupuncture needle entering TH 6 and TH 7, on alternate aspects of the extensor digiti minimi muscle.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus, extensor indicis, extensor digitorum, extensor digiti minimi, and extensor carpi ulnaris muscles. Also supplies the posterior surface of the interosseous membrane.

Clinical Relevance: Fractures of the thoracic limb can injure peripheral nerves. Radial neck fracture may lead to injuries of the posterior interosseous and ulnar nerves.[7] Displacement of bone after high-energy trauma places traction on the nerve. Iatrogenic entrapment following fracture reduction can compress the nerves. Conservative management that includes acupuncture, massage, and/or laser therapy addresses neuropathic pain and aids in functional restoration.

The posterior interosseous nerve passes deep to the arcade of Frohse, otherwise known as the supinator arch. This superficial layer of the supinator muscle may entrapment the posterior interosseous nerve by means of Schwannoma, or through extrinsic compression with fibrous brands, ganglion cysts, fractures, etc.[8]

Deep needling of TH points distal to the elbow risks injuring the posterior interosseous nerve, which can cause progressive wrist drop. The posterior interosseous nerve supplies wrist and digital extensors. Mechanisms of neurotrauma secondary to acupuncture include compressive neuropathy following surrounding hematoma, irritation by a fractured needle tip, or laceration of the nerve through vigorous, deep needling.[9]

Vessels

- **Posterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The posterior interosseous artery gives rise to the recurrent interosseous artery, which participates in the anastomoses around the elbow joint.
- **Posterior interosseous vein:** These deep veins accompany the interosseous arteries. The drain into the veins accompanying the radial and ulnar arteries.

Clinical Relevance: Acupuncture and related techniques implemented along the distal TH line may improve circulation for patients with peripheral vascular disease affecting ring or little finger mobility and/or tissue health. Hematomata or aneurysms of vessels in the extensor surface groove between radius and ulna may compress the posterior interosseous nerve.[10]

Indications and Potential Point Combinations

- **Pain in the thoracic limb:** Locate responsible trigger points or other painful structures; consider radiating pain from the cervical spine. Add TH 7 for pain along the TH line on the thoracic limb.

Figure 10-21. Trigger points in muscles present in this cross section at TH 8 may refer pain into the wrist and/or ring finger. Deep antebrachial pain or ache from the abductor pollicis longus muscle may refer from TH 8 to LI 5 (the anatomical snuffbox).

The posterior interosseous nerve passes deep to the arcade of Frohse, otherwise known as the supinator arch. This superficial layer of the supinator muscle may entrapment the posterior interosseous nerve by means of Schwannoma, or through extrinsic compression with fibrous brands, ganglion cysts, fractures, etc.[9]

Deep needling of TH points distal to the elbow risks injuring the posterior interosseous nerve, which can cause progressive wrist drop. The posterior interosseous nerve supplies wrist and digital extensors. Mechanisms of neurotrauma secondary to acupuncture include compressive neuropathy following surrounding hematoma, irritation by a fractured needle tip, or laceration of the nerve through vigorous, deep needling.[10]

Vessels

- **Posterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The posterior interosseous artery gives rise to the recurrent interosseous artery, which participates in the anastomoses around the elbow joint.
- **Posterior interosseous vein:** These deep veins accompany the interosseous arteries. The drain into the veins accompanying the radial and ulnar arteries.

Clinical Relevance: Acupuncture and related techniques implemented along the distal TH line may improve circulation for patients with peripheral vascular disease affecting ring or little finger mobility and/or tissue health. Hematomata or aneurysms of vessels in the extensor surface groove between radius and ulna may compress the posterior interosseous nerve.[11]

Indications and Potential Point Combinations

- **Pain in the thoracic limb:** Locate responsible trigger points or other painful structures; consider radiating pain from the cervical spine. Add TH 8 if tender for pain along the TH line on the thoracic limb.
- **Pain resembling de Quervain's tenosynovitis:** Rule out referred pain from the abductor pollicis longus muscle that can mimic de Quervain's tenosynovitis. TH 8, LI 5, SI 6.[1]
- **Aphasia:**[12,13] TH 8.

TH 9

Si Du "Four Rivers"

On the dorsal antebrachium, in a depression 7 cun proximal to the dorsal wrist crease, or 5 cun distal to the olecranon, between the radius and the ulna, on a line drawn between TH 4 and the lateral humeral epicondyle. Divide the distance between TH 4 and the lateral epicondyle into two equal parts. Find TH 9 at a location that is 1 cun proximal to this midpoint, between the bellies of the extensor digitorum and extensor carpi ulnaris muscles, directly over the extensor digiti minimi muscle belly. Ask the patient to extend and move about the little finger to identify the location of the muscle. This region often elicits tenderness to palpation.

Connective Tissues

- **Interosseous membrane between the radius and ulna:** Binds the two bones of the forearm. Allows load on the forearm to distribute between the radius and ulna. The interosseous membrane is a complex structure consisting of a central band, proximal interosseous band, membranous portions, and accessory bands. The central portion of the interosseous membrane possesses the most strength, considered by some tantamount in strength to the anterior cruciate ligament or patellar tendon. The anterior interosseous vessels and nerve supply the PC (volar) surface of the membrane; the posterior interosseous counterparts supply the TH (dorsal) surface, in conjunction with a dorsal branch of the anterior interosseous vessels.

The interosseous membrane provides longitudinal stability to the forearm.[1] The forearm acts as a joint with the interosseous membrane serving as the ligamentous connection.[2] The forearm complex, or joint, supports forearm function; rotation of the radius around the ulna is required for activities of daily living such as eating and maintaining personal hygiene.[3]

Clinical Relevance: High-force compressive trauma can injure the forearm and elbow, tearing the membrane, fracturing the radial head, and causing failure of the triangular fibrocartilage complex. Instability of the forearm leads to considerable pain and debility by limiting antebrachial motion and disturbing the biomechanics of the wrist.[4] One injury pattern that precipitates forearm instability involves axial load transmitted through the wrist to the elbow. The diagnosis is often overlooked; early recognition and effective care improve outcomes, as only a fifth of patients with delayed intervention experience satisfactory recovery.[5] Whether or not patients pursue surgery, restoring soft tissue stability remains a critical component in the treatment of chronic radioulnar dissociation injury. Nonsurgical means of improving tissue health and proprioception include acupuncture and related techniques. Laser therapy fosters tissue healing. Massage lessens myofascial restriction and improves proprioception and circulation, as does acupuncture.

Muscles

- **Extensor carpi ulnaris muscle:** Extends and adducts the hand at the wrist.
- **Extensor digitorum muscle:** The chief extensor of the medial four digits. Extends the digits at the metacarpophalangeal joints and extends the hand at the wrist.
- **Extensor digiti minimi muscle:** Extends the little finger at both the metacarpophalangeal and interphalangeal joints.

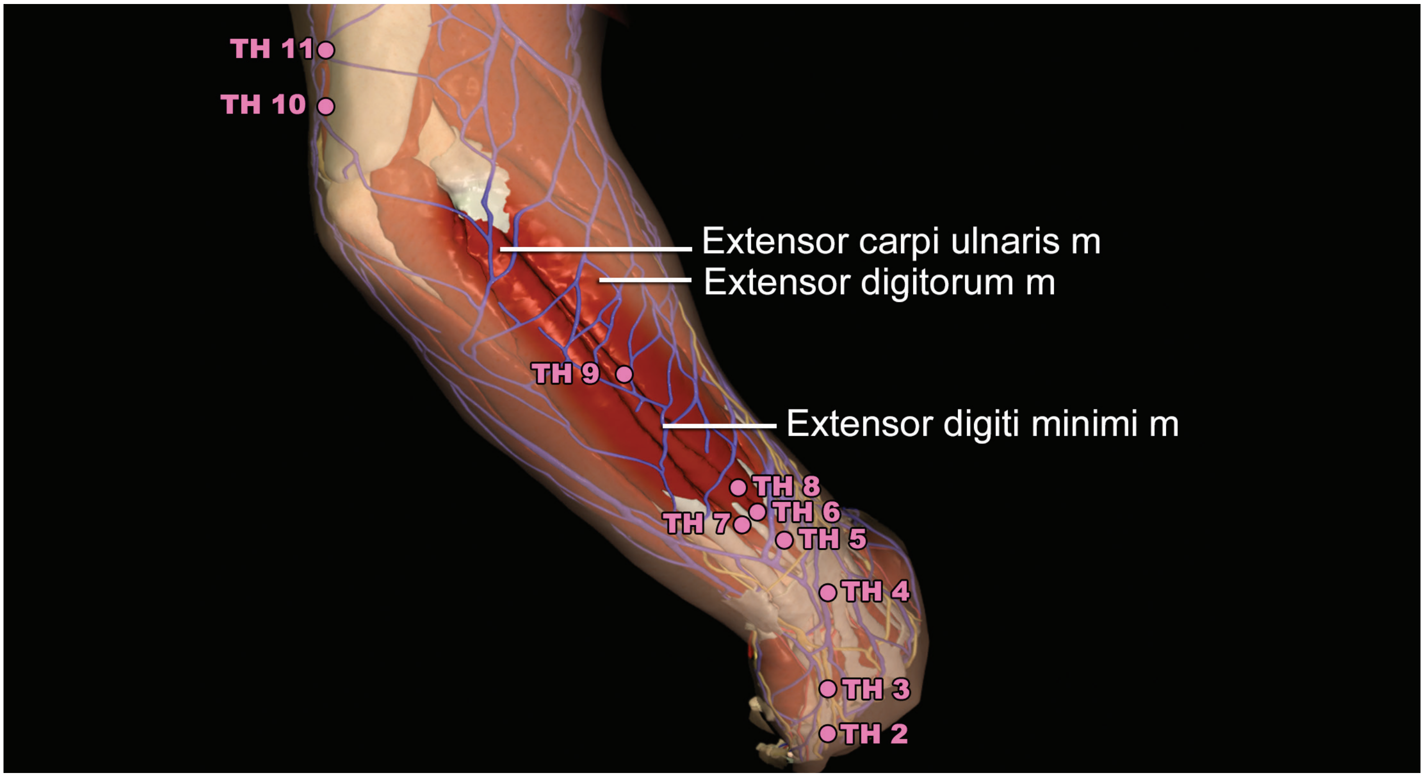

Figure 10-22. TH 9 stands alone on the mid-antebrachium. Its name, "Four Rivers", pertains either to the four extensor tendons fanning from this region to the fingers, or it may instead refer to the four extensor muscles within reach of a needle entering TH 9. These muscles include the extensor digitorum, extensor digiti minimi, extensor pollicis longus, and extensor carpi ulnaris muscles, as indicated in Figure 10-23.

- **Extensor pollicis longus muscle:** Extends the proximal phalanx of the thumb at the carpometacarpal joint.
- **Abductor pollicis longus muscle:** Abducts the thumb. Extends the thumb at the carpometacarpal joint.

Clinical Relevance: Myotendinous dysfunction in the vicinity of TH 9 may limit or otherwise disturb function in the ring or little fingers. Acupuncture, massage, and laser therapy may improve symptoms arising from degenerative joint disease or other causes of arthralgia and arthrosis of the 4th and 5th metacarpophalangeal joints. Physical medicine techniques such as these, including electroacupuncture, assist in ameliorating mechanical and neurologic dysfunction of the wrist and hand after central nervous system injury, often in accordance with measures to strengthen voluntary flexion and extension.

A trigger point in ring finger extensor and extensor digiti minimi muscle near TH 9 typically refers pain along the TH trajectory toward TH 2. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles can also refer pain along the distal TH line.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm.
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus, extensor indicis, extensor digitorum, extensor digiti minimi, and extensor carpi ulnaris muscles. Also supplies the posterior surface of the interosseous membrane.

Clinical Relevance: Fractures of the thoracic limb can injure peripheral nerves. Radial neck fracture may lead to injuries of the posterior interosseous and ulnar nerves.[6] Displacement of bone after high-energy trauma places traction on the nerve. Iatrogenic entrapment following fracture reduction can compress the nerves. Conservative management that includes acupuncture, massage, and/or laser therapy addresses neuropathic pain and aids in functional restoration.

The posterior interosseous nerve passes deep to the arcade of Frohse, otherwise known as the supinator arch. This superficial layer of the supinator muscle may entrapment the posterior interosseous nerve by means of Schwannoma, or through extrinsic compression with fibrous brands, ganglion cysts, fractures, etc.[7]

Deep needling of TH points distal to the elbow risks injuring the posterior interosseous nerve, which can cause progressive wrist drop. The posterior interosseous nerve supplies wrist and digital extensors. Mechanisms of neurotrauma secondary to acupuncture include compressive neuropathy following surrounding hematoma, irritation by a fractured needle tip, or laceration of the nerve through vigorous, deep needling.[8]

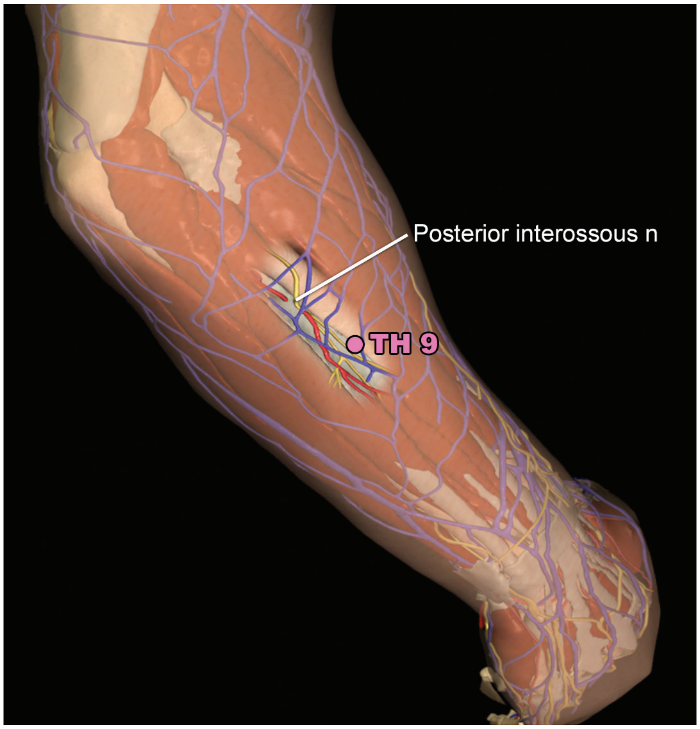

Figure 10-23. Deeply needling TH 9 can damage the posterior interosseous nerve, shown here.[10]

Vessels

- **Posterior interosseous artery:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The posterior interosseous artery gives rise to the recurrent interosseous artery, which participates in the anastomoses around the elbow joint.
- **Posterior interosseous vein:** These deep veins accompany the interosseous arteries. The drain into the veins accompanying theradial and ulnar arteries.

Clinical Relevance: Acupuncture and related techniques along the distal TH line may improve circulation for patients with peripheral vascular disease affecting ring or little finger mobility and/or tissue health. Hematomata or aneurysms of vessels in the dorsal groove between radius and ulna may compress the posterior interosseous nerve.[9]

Indications and Potential Point Combinations

- **Dorsal forearm, wrist, and hand pain:** Identify, to the extent possible, the source of the problem, be it trigger points in the digital extensors or the abductor pollicis longus, arthrodial elements, bone pain, or neuropathic pain. Select points accordingly, to address both the source (such as TH 9 for the noted trigger points) and the pain referral pattern (e.g., TH 5, TH 4, TH 3, and TH 2). Trigger points in the digital extensors typically issue referred pain along the TH line while myofascial dysfunction in the abductor pollicis longus will refer pain over to LI 5.

TH 10

Tian Jing "Celestial Well"

On the dorsal elbow region, in the depression that appears 1 cun proximal to the tip of the olecranon process when the elbow flexes.

Tendons

- **Triceps brachii tendon:** Serves as the main extensor of the forearm. The long head steadies the head of the humerus of the abducted arm. Fibers from the three heads of the triceps brachii converge into a single tendon that inserts onto the olecranon process of the ulna as well as to the caudal wall of the elbow joint capsule where bursae may exist. Portions of the common tendon extend into the antebrachial fascia; these fibers may cover the anconeus muscle.

Clinical Relevance: In healthy adults, it takes substantial force to rupture the triceps brachii tendon, either completely or as a partial tear.[2] In addition to examining the tendon, clinicians should test for ulnar nerve injury or tunnel syndrome, which can complicate triceps tendon rupture. Most individuals with low functional demand tolerate a partial lesion fairly well, though pain may persist with triceps activation. The severe, sudden pain resolves relatively soon after the trauma, but patients may complain of reduced arm strength with elbow extension. Incorporation of acupuncture, laser therapy, and massage may aid in the recovery of the tissue and augment the ability to return to full function, whether or not surgery for a partial triceps tendon tear is pursued.

Trigger points in the long head of the triceps brachii muscle send telltale pain patterns along the entire TH channel, from TH 15 to TH 4. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles refer pain along the TH line toward the ring finger. A teres major trigger point issues pain strongly to the dorsal shoulder from TH 14 to SI 10 and distad to TH territory on the brachium and antebrachium. Teres minor trigger points send pain to TH 14, TH 13, and down the TH line toward TH 11. Referred pain from subscapularis trigger points covers the entire scapular region and centralizes over the dorsal shoulder from TH 14 to TH 13. The pain continues to TH 10 and then hops over the dorsal surface of the antebrachium to land at TH 4, spreading to the entire wrist with the dorsal aspect more intensely affected. Caudal deltoid trigger points extend from TH 14/SI 10 to TH 13, TH 12, and LI 11. Pain from coracobrachialis dysfunction may start at LU 2 but then migrate caudad toward LI 15 to focus heavily on the caudal brachium from TH 13 to TH 12, and TH 9 to TH 3.

Nerves

- **Posterior brachial cutaneous nerve:** A branch of the radial nerve that supplies the skin on the posterior surface of the brachium.

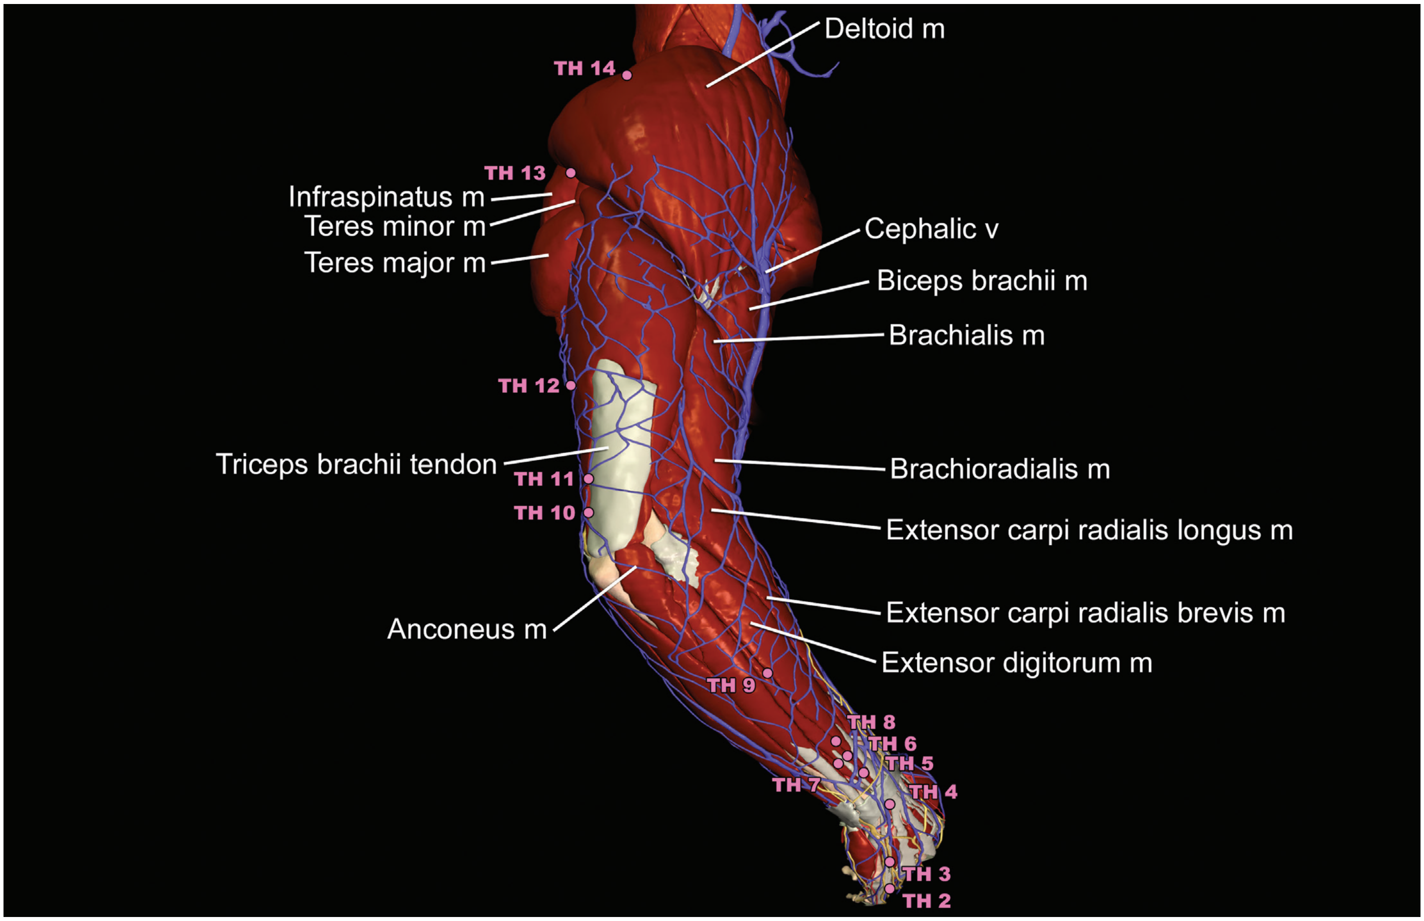

Figure 10-25. TH 10 sits in a well just proximal to the olecranon process. The Chinese character combination Tian Jing that identifies TH 10 as "Celestial Well" connotes a small pond surrounded by high cliffs (See Ellis A et al, Grasping the Wind, p. 239). The "pond" in this case is the depression palpated here, adjacent to the olecranon process, the "high cliff".

Figure 10-26. This dorsal view of the elbow illustrates how closely TH 10 and TH 11 follow neurovascular structures. It becomes evident how a supracondylar fracture could disrupt nerve and blood supply to this section of the limb.

- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium, including the triceps brachii muscle. It divides into superficial and deep branches near the elbow. The deep branch further splits into muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist. Note in Figure 10-26 that the radial nerve branch deep to TH 10 is on its way to supply the anconeus muscle.
- **Intercostobrachial nerve (T2):** The ventral ramus of the 2nd thoracic spinal nerve divides into branches, the 2nd intercostal nerve (which is the larger of the two) and a smaller branch, which joins the brachial plexus. This smaller branch constitutes the lateral cutaneous branch of the 2nd intercostal nerve and is called the intercostobrachial nerve. It emerges from the 2nd intercostal space at the midaxillary line and penetrates the serratus anterior muscle to enter the brachial region, i.e., the axilla and arm. The floor of the axilla (i.e., the skin and its underlying subcutaneous tissue) receives its innervation from the intercostobrachial nerve. The intercostobrachial nerve communicates with the medial brachial cutaneous nerve to supply the posterior and medial surfaces of the arm. The intercostobrachial nerve may also communicate with the posterior brachial cutaneous nerve, a branch of the radial nerve.

Clinical Relevance: All major nerves of the thoracic limb, except the axillary nerve and medial brachial cutaneous nerve, send terminal articular branches to the elbow. These nerve endings issue from muscular nerves, cutaneous nerves, or nerves that arise directly from the brachial plexus.[3]

The myotendinous junction of the triceps brachii muscle deep to TH 10 indicates the presence of Golgi tendon organs and the opportunity to neuromodulate muscle tension and tone.

TH 10 also serves as a site of referred pain from the T2 region. As such, patients displaying tenderness to palpation from the upper thoracic paraspinal region to the axilla, caudal brachium, and dorsal antebrachium may benefit from a comprehensive treatment involving BL 11, BL 12, SI 9, TH 10, and distal TH or LI sites. A complete myofascial palpation evaluation should elucidate sources of somatic dysfunction. The clinical picture along with the pain pattern ultimately determines the neuromodulation protocol.

The extrathoracic course of the intercostobrachial nerve exhibits a variety of courses between individuals, putting it at risk of damage during surgical procedures of the chest wall such as mastectomy and axillary node clearance.[4]

Interrelationships of nerves supplying TH 10, such as the intercostobrachial nerve, provide sources of referred cardiac pain.

Vessels

- **Deep brachial artery, middle collateral branch:** Participates in the arterial anastomoses around the elbow joint. The middle collateral branch joins with the inferior ulnar collateral artery, the anterior ulnar recurrent artery, the posterior ulnar recurrent artery, and the superior ulnar collateral artery. The middle

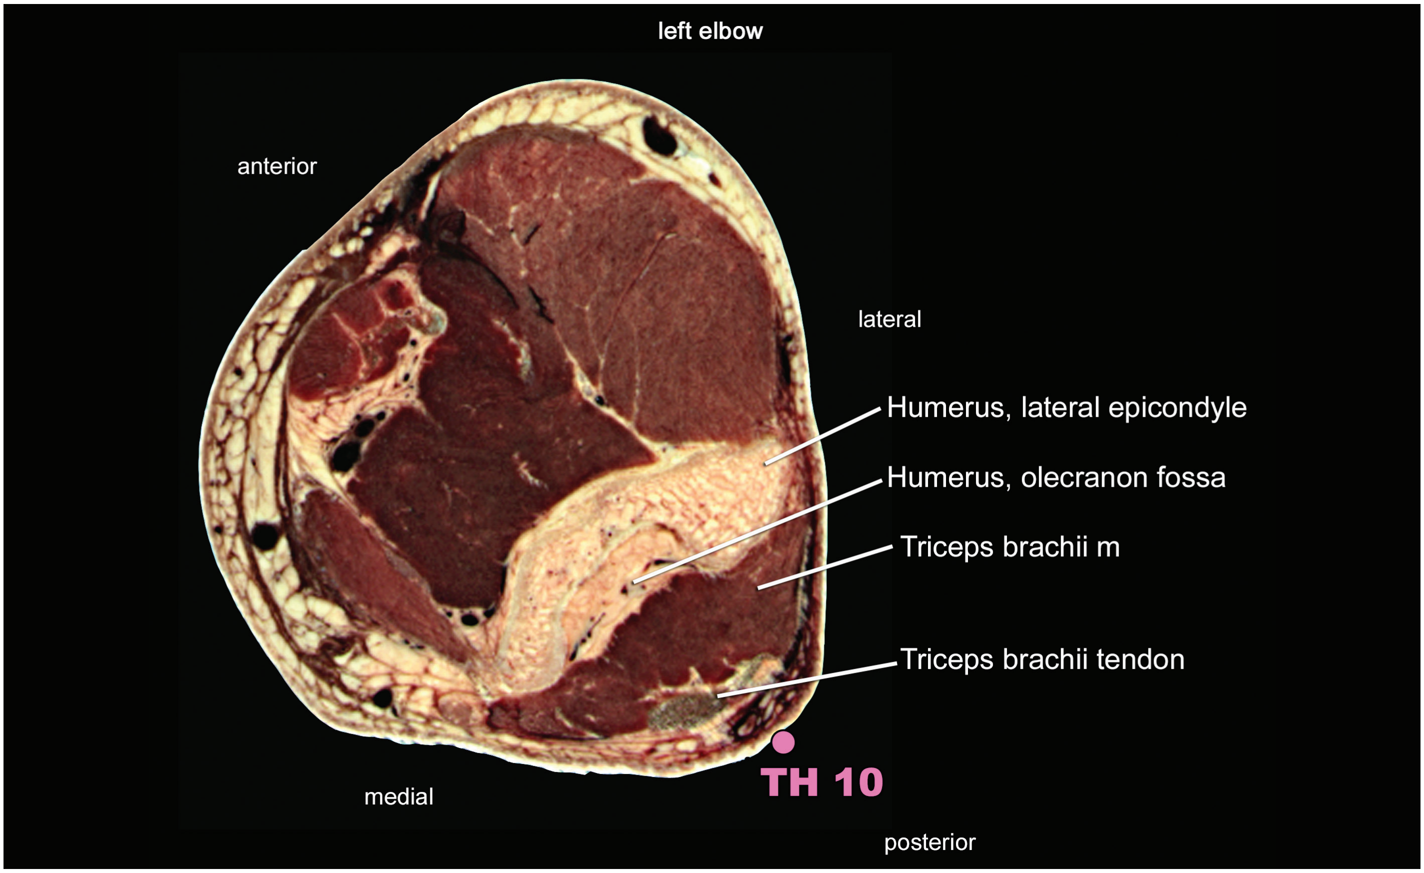

Figure 10-27. TH 10 Influences a host of structures implicated in elbow pain and mechanical dysfunction, including the triceps tendon and muscle, the radial nerve, and local blood supply and drainage channels.

collateral artery (also called the medial collateral artery) anastomoses as well with the interosseous recurrent artery near the elbow. See Figure 10-26 to examine this relationship.

Clinical Relevance: Supracondylar fractures of the distal humerus happen commonly in children and can cause neurovascular compromise.[5] Laser therapy may prematurely close epiphyses in immature patients. As such, after accurate neurovascular evaluation has assessed damage to vulnerable periarticular structures, other physical medicine measures may be preferable to revitalize the region and restore circulation and neurologic function.

The cross-section in Figure 10-27 discloses the abundant vascularity of the tissue deep to TH 10; note the extensive hemorrhage in the subcutaneous layer.

Indications and Potential Point Combinations

- **Lateral thoracic pain:** Consider trigger points in the subscapularis muscle, producing a pain referral pattern that centers in the SI 9/SI 10 region and extends to SI 11, SI 12, TH 11, TH 12, TH 14, TH 4, and PC 7. Needle appropriate trigger points and consider relevant spinal segments from C5 to T2.[6]
- **Neck, shoulder, arm, or elbow pain:** Palpate for triceps brachii trigger points. Myofascial dysfunction in the long head of the triceps refers pain to GB 21, SI 10, TH 14, TH 12, TH 11, TH 10, LI 11, LI 10, TH 9 to TH 4 and TH 3. Trigger points in the lateral triceps brachii may centralize over TH 10 and refer pain to the olecranon process. Trigger points within the medial head of the triceps brachii muscle begin near TH 10 and HT 2 and descend along the HT line. Needle appropriate trigger points and consider relevant spinal segments.
- **Thoracic limb spasticity after stroke:** TH 10, TH 4, LI 15; may also add HT 1, LU 5, and PC 7; electroacupuncture indicated.[7]

Evidence-Based Applications

- Dry needling at TH 10, TH 4, LI 15, PC 7, LU 5, and HT 1 performed as well as electroacupuncture for patients with **upper limb spasticity after stroke.** Both treatments significantly alleviated muscle spasm, improved motor function, and activities of daily living.[1]
- Patients with **chronic obstructive pulmonary disease (COPD)** experienced significant improvements in pulmonary function after receiving acupuncture at TH 10, TH 6, LI 11, LI 10, LU 7, and LU 5 as compared to those who received rehabilitation alone.[8]

TH 11

Qing Leng Yuan "Clear Cold Abyss"

On the caudal brachial region, 1 cun proximal to TH 10, or 2 cun proximal to the tip of the olecranon process.

Muscles and Tendons

- **Triceps brachii muscle or tendon:** Serves as the main extensor of the forearm. The long head steadies the head of the humerus of the abducted arm. Fibers from the three heads of the triceps brachii converge into a single tendon that inserts onto the olecranon process of the ulna as well as to the caudal wall of the elbow joint capsule where bursae may exist. Portions of the common tendon extend into the antebrachial fascia; these fibers may cover the anconeus muscle.

Clinical Relevance: In healthy adults, it takes substantial force to rupture the triceps brachii tendon, either completely or as a partial tear.[1] In addition to examining the tendon, clinicians should test for ulnar nerve injury or tunnel syndrome, which can complicate triceps tendon rupture. Most individuals with low functional demand tolerate a partial lesion fairly well, though pain may persist with triceps activation. The severe, sudden pain resolves relatively soon after the trauma, but patients may complain of reduced arm strength with elbow extension. Incorporation of acupuncture, laser therapy, and massage may aid in the recovery of the tissue and augment the ability to return to full function, whether or not surgery for a partial triceps tendon tear is pursued.

Nerves

- **Posterior brachial cutaneous nerve:** A branch of the radial nerve that supplies the skin on the posterior surface of the brachium.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium, including the triceps brachii muscle. It divides into superficial and deep branches near the elbow. The deep branch further splits into muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist. Note in Figure 10-29 that the radial nerve branch deep to TH 10 is on its way to supply the anconeus muscle.
- **Intercostobrachial nerve (T2):** The ventral ramus of the 2nd thoracic spinal nerve divides into branches, the 2nd intercostal nerve (which is the larger of the two) and a smaller branch, which joins the brachial plexus. This smaller branch constitutes the lateral cutaneous branch of the 2nd intercostal nerve and is called the intercostobrachial nerve. It emerges from the 2nd

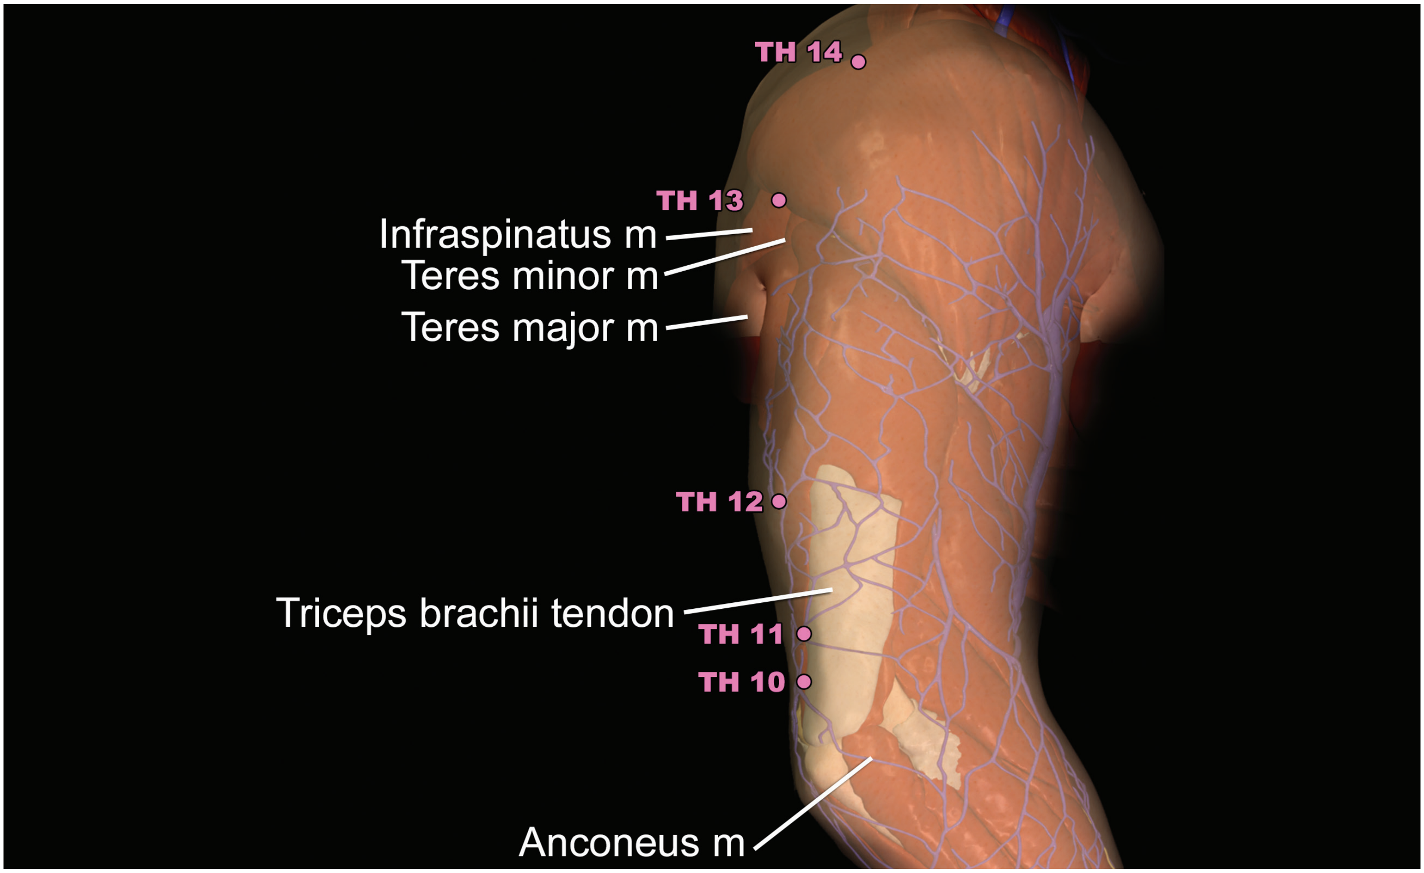

Figure 10-28. Both TH 10 and TH 11 reside over the tendon and underlying musculature of the triceps brachii. Either or both may become tender due to myofascial dysfunction in the triceps brachii muscle. Fascia from the triceps tendon extends to the anconeus muscle, distolateral to TH 11 and TH 10.

TH 10

Figure 10-29. The rationale for naming TH 11 "Clear Cold Abyss" may pertain to the ability of the point to reduce a sensation of heat along the channel.

intercostal space at the midaxillary line and penetrates the serratus anterior muscle to enter the brachial region, i.e., the axilla and arm. The floor of the axilla (i.e., the skin and its underlying subcutaneous tissue) receives its innervation from the intercostobrachial nerve. The intercostobrachial nerve communicates with the medial brachial cutaneous nerve to supply the posterior and medial surfaces of the arm. The intercostobrachial nerve may also communicate with the posterior brachial cutaneous nerve, a branch of the radial nerve.

Clinical Relevance: All major nerves of the thoracic limb, except the axillary nerve and medial brachial cutaneous nerve, send terminal articular branches to the elbow. These nerve endings issue from muscular nerves, cutaneous nerves, or nerves that arise directly from the brachial plexus.[2]

The myotendinous junction of the triceps brachii muscle deep to TH 11 indicates the presence of Golgi tendon organs and the opportunity to neuromodulate muscle tension and tone.

TH 11 also serves as a site of referred pain from the T2 region. As such, patients displaying tenderness to palpation from the upper thoracic paraspinal region to the axilla, caudal brachium, and dorsal antebrachium may benefit from a comprehensive treatment involving BL 11, BL 12, SI 9, TH 11, TH 10, and distal TH or LI sites. A complete myofascial palpation evaluation should elucidate sources of somatic dysfunction. The clinical picture along with the pain pattern ultimately determines the neuromodulation protocol.

The extrathoracic course of the intercostobrachial nerve exhibits a variety of courses between individuals, putting it at risk of damage during surgical procedures of the chest wall such as mastectomy and axillary node clearance.[3]

Interrelationships of nerves supplying TH 11, such as the intercostobrachial nerve, provide sources of referred cardiac pain.

Vessels

- **Deep brachial artery (or deep artery of the arm), middle collateral branch:** Participates in the arterial anastomoses around the elbow joint. The middle collateral branch joins with the inferior ulnar collateral artery, the anterior ulnar recurrent artery, the posterior ulnar recurrent artery, and the superior ulnar collateral artery. The middle collateral artery (also called the medial collateral artery) anastomoses as well with the interosseous recurrent artery near the elbow. See Figure 10-26 to examine this relationship.
- **Superior ulnar collateral artery:** This artery arises from the brachial artery near the middle of the arm and travels with the ulnar nerve toward the humerus. It anastomoses with the posterior branch of the ulnar recurrent artery and inferior ulnar collateral artery which participate in the elbow anastomoses.
- Inferior ulnar collateral artery: This artery arises from the brachial artery about 5 cm proximal to the cubital crease. It joins the elbow anastomoses via its connection with the anterior branch of the ulnar recurrent artery.

Clinical Relevance: Supracondylar fractures of the distal humerus happen commonly in children and can cause neurovascular compromise.[4] Laser therapy may prematurely close epiphyses in immature patients. As such, after accurate neurovascular evaluation has assessed damage to vulnerable periarticular structures, other physical medicine measures may be preferable to revitalize the region and restore circulation and neurologic function.

The cross-section in Figure 10-30 discloses the abundant vascularity of the tissue deep to TH 11; note the extensive hemorrhage in the subcutaneous layer.

Indications and Potential Point Combinations

- **Back pain:** Latissimus dorsi trigger points in the GB 22, GB 23, and LR 13 vicinities may refer pain along the TH and HT lines.
- **Neck pain:** Identify the dysfunction involved and treat accordingly. For neck pain that radiates to the medial scapula, shoulder, pectoral region, and thoracic limb (along the TH and LI lines), evaluate the anterior, middle, and posterior scalene muscles as well as the scalenes minimus for trigger points. In addition to addressing the trigger points directly, consider adding points along the TH line such as TH 10, TH 11, and TH 4.
- **Shoulder pain:** Palpate for supraspinatus trigger point radiating to the shoulder and distal limb (LI 15, TH 14, LI 14, TH 11, TH 10, and LI 11). Evaluate the infraspinatus muscle for trigger points that may refer pain to the LI, TH, and LU lines of the thoracic limb and the medial scapula (BL 13, BL 14, and BL 15) and needle accordingly. Subscapularis trigger points can issue pain along the TH and SI lines; while inaccessible to needling, they can be reached via soft tissue maneuvers. Coracobrachialis trigger points in the LI 15/LU 2 region produces a referred pain pattern

along the TH line, including TH 11 and TH 10, down to the TH 3.

- **Posterior arm pain:** TH 11 applications most closely pertain to the triceps brachii muscle and tendon, upon which it sits. An attachment trigger point deep under the triceps tendon, in the musculotendinous attachment region of the lateral head resides directly beneath TH 11. In addition, check the teres minor muscle at SI9 for a trigger point that refers pain to the TH 14, TH 13, TH 12, and TH 11 regions.

TH 12

Xiao Luo "Dispersing Riverbed", "Relieving Thirst"

On the posterolateral brachium, on a line drawn from TH 14 to the olecranon, 4 cun proximal to TH 10, on the lower margin of the bulge of the lateral head of the triceps muscle when the forearm is pronated. In a depression in the triceps muscle, posterior to the humerus and between the long and lateral heads of the triceps muscle. Approximately midway between TH 11 and TH 13; about 1 cun distal to the midpoint between TH 10 and TH 14. Locate with elbow flexed and forearm in pronation. See Figure 10-31 for a pictorial depiction of its location.

Muscles

- **Triceps brachii muscle:** Serves as the main extensor of the forearm. The long head steadies the head of the humerus of the abducted arm. Fibers from the three heads of the triceps brachii converge into a single tendon that inserts onto the olecranon process of the ulna as well as to the caudal wall of the elbow joint capsule where bursae may exist. Portions of the common tendon extend into the antebrachial fascia; these fibers may cover the anconeus muscle.

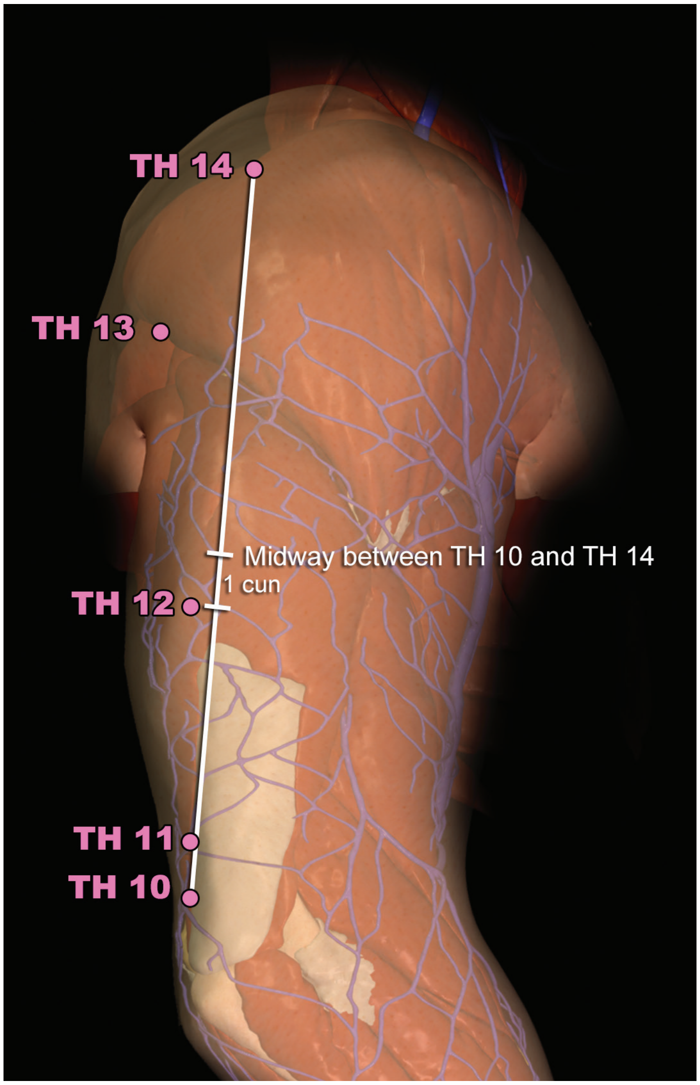

Figure 10-31. TH 12 accesses central trigger points in the triceps brachii muscle, in contrast to the attachment trigger points of TH 10 and TH 11.

Clinical Relevance: In healthy adults, it takes substantial force to rupture the triceps brachii tendon, either completely or as a partial tear.[1] In addition to examining the tendon, clinicians should test for ulnar nerve injury or tunnel syndrome, which can complicate triceps tendon rupture. Most individuals with low functional demand tolerate a partial lesion fairly well, though pain may persist with triceps activation. The severe, sudden pain resolves relatively soon after the trauma, but patients may complain of reduced arm strength with elbow extension. Incorporation of acupuncture, laser therapy, and massage may aid in the recovery of the tissue and augment the ability to return to full function, whether or not surgery for a partial triceps tendon tear is pursued.

Trigger points in the long head of the triceps brachii muscle send telltale pain patterns along the entire TH channel, from TH 15 to TH 4. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles refer pain along the TH line toward the ring finger. A teres major trigger point issues pain strongly to the dorsal shoulder from TH 14 to SI 10 and distad to TH territory on the brachium and antebrachium. Teres minor trigger points send pain to TH 14, TH 13, and down the TH line toward TH 11. Referred pain from subscapularis trigger points covers the entire scapular region and centralizes over the dorsal shoulder from TH 14 to TH 13. The pain continues to TH 10 and then hops over the dorsal surface of the antebrachium to land at TH 4, spreading to the entire wrist with the dorsal aspect more intensely affected. Caudal deltoid trigger points extend from TH 14/SI 10 to TH 13, TH 12, and LI 11. Pain from coracobrachialis dysfunction may start at LU 2 but then migrate caudad toward LI 15 to focus heavily on the caudal brachium from TH 13 to TH 12, and TH 9 to TH 3.

Nerves

- **Posterior brachial cutaneous nerve:** A branch of the radial nerve that supplies the skin on the posterior surface of the brachium.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium, including the triceps brachii muscle. It divides into superficial and deep branches near the elbow. The deep branch further divides into muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.
- **Intercostobrachial nerve (T2):** The ventral ramus of the 2nd thoracic spinal nerve divides into branches, the 2nd intercostal nerve (which is the larger of the two) and a smaller branch, which joins the brachial plexus. This smaller branch constitutes the lateral cutaneous branch of the 2nd intercostal nerve and is called the intercostobrachial nerve. It emerges from the 2nd

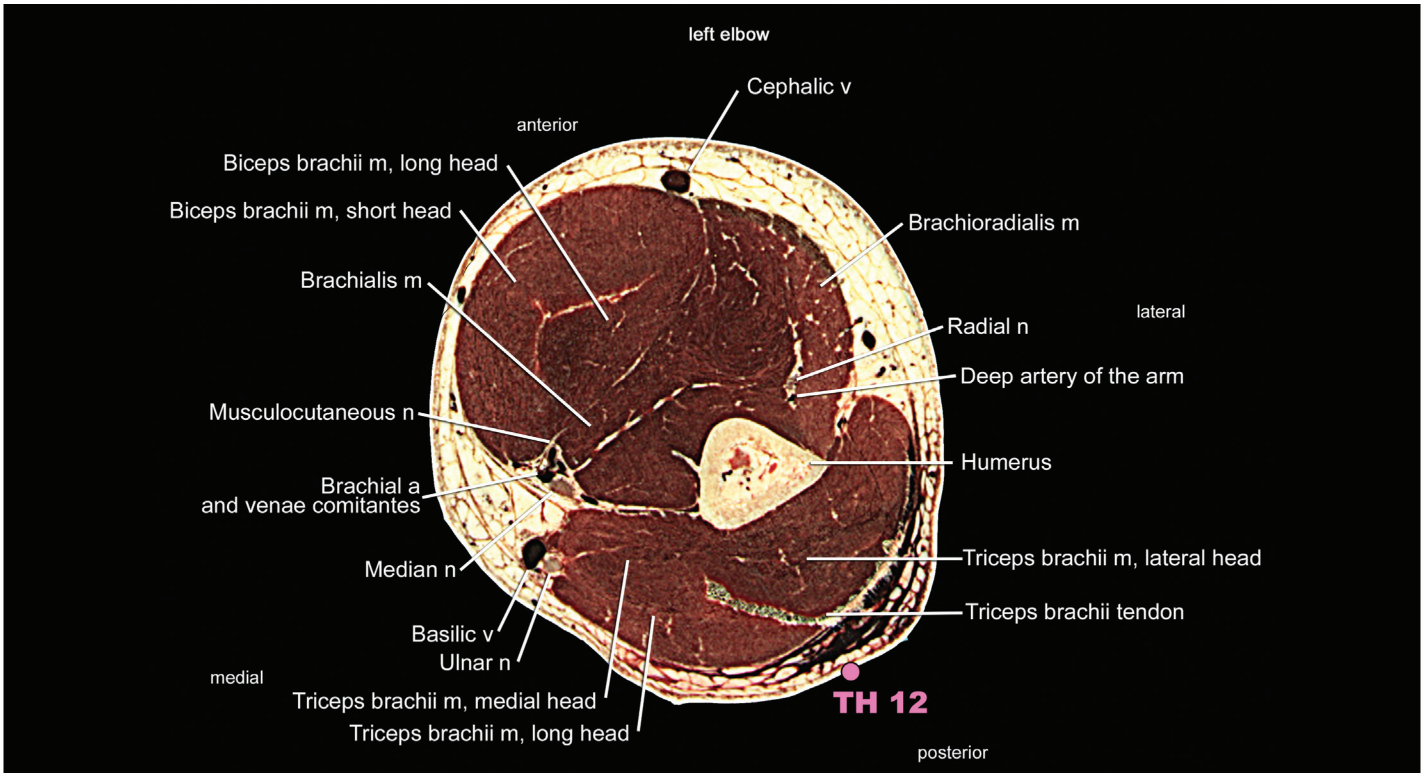

Figure 10-32. Depending on the direction of needle insertion, TH 12 needling may reach trigger points in the lateral, long, or medial head of the triceps brachii muscle. All three appear in this cross-section.

intercostal space at the midaxillary line and penetrates the serratus anterior muscle to enter the brachial region, i.e., the axilla and arm. The floor of the axilla (i.e., the skin and its underlying subcutaneous tissue) receives its innervation from the intercostobrachial nerve. The intercostobrachial nerve communicates with the medial brachial cutaneous nerve to supply the posterior and medial surfaces of the arm. The intercostobrachial nerve may also communicate with the posterior brachial cutaneous nerve, a branch of the radial nerve.

Clinical Relevance: All major nerves of the thoracic limb, except the axillary nerve and medial brachial cutaneous nerve, send terminal articular branches to the elbow. These nerve endings issue from muscular nerves, cutaneous nerves, or nerves that arise directly from the brachial plexus.[2]

TH 12 also serves as a site of referred pain from the T2 region. As such, patients displaying tenderness to palpation from the upper thoracic paraspinal region to the axilla, caudal brachium, and dorsal antebrachium may benefit from a comprehensive treatment involving BL 11, BL 12, SI 9, TH 12, TH 11, TH 10, and distal TH or LI sites. A complete myofascial palpation evaluation should elucidate sources of somatic dysfunction. The clinical picture along with the pain pattern ultimately determines the neuromodulation protocol.

The extrathoracic course of the intercostobrachial nerve exhibits a variety of courses between individuals, putting it at risk of damage during surgical procedures of the chest wall such as mastectomy and axillary node clearance.[3]

Interrelationships of nerves supplying TH 12, such as the intercostobrachial nerve, provide sources of referred cardiac pain.

Vessels

- **Deep brachial artery, middle collateral branch:** Participates in the arterial anastomoses around the elbow joint. The middle collateral branch joins with the inferior ulnar collateral artery, the anterior ulnar recurrent artery, the posterior ulnar recurrent artery, and the superior ulnar collateral artery. This deep artery of the arm, also know as the profunda brachii artery, arise from the lateral and posterior portions of the brachial artery, just distal to the teres major muscle. The deep brachial artery closely follows the radial nerve, coursing between the medial and lateral heads of the triceps brachii and then along the radial nerve groove (or sulcus) of the humerus under cover of the lateral head of the triceps. It pierces the lateral intermuscular septum and descends between the brachioradialis and brachialis toward the cranial aspect of the lateral epicondyle of the humerus. It ends in an anastomosis with the radial recurrent artery.
- **Superior ulnar collateral artery:** This artery arises from the brachial artery near the middle of the arm and travels with the ulnar nerve toward the humerus. It anastomoses with the posterior branch of the ulnar recurrent artery and inferior ulnar collateral artery which participate in the elbow anastomoses.

Clinical Relevance: Supracondylar fractures of the distal humerus happen commonly in children and can cause neurovascular compromise.[4] Laser therapy may prematurely close epiphyses in immature patients. As such, after accurate neurovascular evaluation has assessed damage to vulnerable periarticular structures, other physical medicine measures may be preferable to revitalize the region and restore circulation and neurologic function.

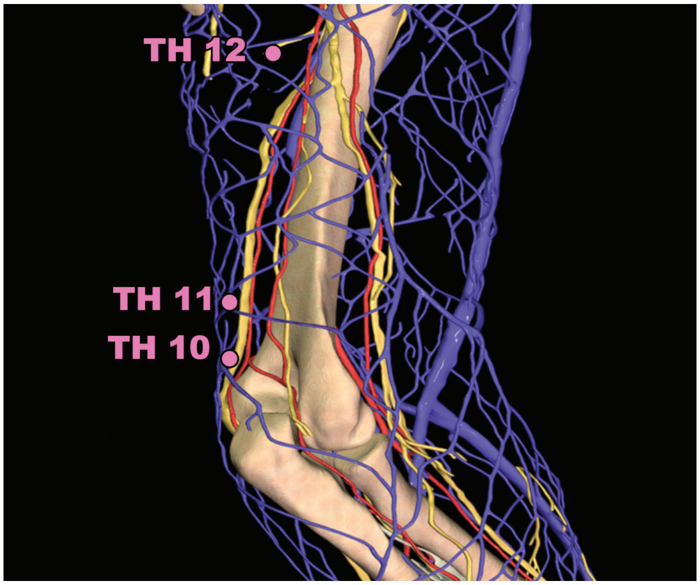

Figure 10-33. The name for TH 12, "Dispersing Riverbed", applies to the diverging vessels and nerves found at this point, as shown here.

Indications and Potential Point Combinations

- **Back pain:** Latissimus dorsi trigger points in the GB 22, GB 23, and LR 13 vicinities may refer pain along the TH and HT lines.
- **Neck pain:** Identify the dysfunction involved and treat accordingly. For neck pain that radiates to the medial scapula, shoulder, pectoral region, and thoracic limb (along the TH and LI lines), evaluate the anterior, middle, and posterior scalene muscles as well as the scalenes minimus for trigger points. In addition to addressing the trigger points directly, consider adding points along the TH line such as TH 10, TH 12, TH 11, and TH 4.
- **Shoulder pain:** Palpate for supraspinatus trigger point radiating to the shoulder and distal limb (LI 15, TH 14, LI 14, TH 12, TH 11, TH 10, and LI 11). Evaluate the infraspinatus muscle for trigger points that may refer pain to the LI, TH, and LU lines of the thoracic limb and the medial scapula (BL 13, BL 14, and BL 15) and needle accordingly. Subscapularis trigger points can issue pain along the TH and SI lines; while inaccessible to needling, they can be reached via soft tissue maneuvers. Coracobrachialis trigger points in the LI 15/LU 2 region produces a referred pain pattern along the TH line, including TH 12, TH 11 and TH 10, down to the TH 3.
- **Posterior arm pain:** Check the teres minor muscle at SI 9 for a trigger point that refers pain to the TH 14, TH 13, TH 12, and TH 11 regions.

TH 13

Nao Hui "Upper Arm Convergence"

Between the long and lateral heads of the triceps muscle, where the triceps brachii muscle meets the caudal border of the deltoid muscle. The point lands 3 cun distal to TH 14, along the line connecting TH 10 and TH 14. See Figure 10-34 for point placement.

Muscles

- **Triceps brachii muscle:** Serves as the main extensor of the forearm. The long head steadies the head of the humerus of the abducted arm.

Clinical Relevance: TH 13 lives between the long and lateral heads of the triceps brachii muscle. The long head may often receive innervation by a branch of the axillary nerve, while the radial nerve supplies the lateral and medial heads.[1] Thus, when treating paresis or paralysis of the triceps brachii muscle, neuromodulation should address both radial and axillary nerve points. This suggests selecting SI 9, SI 10, TH 14 for axillary nerve stimulation and TH 12 and LI 12 for radial nerve activation. TH 13 may address both the radial and axillary nerves.

Trigger points in the long head of the triceps brachii muscle send telltale pain patterns along the entire TH channel, from TH 15 to TH 4. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles refer pain along the TH line toward the ring finger. A teres major trigger point issues pain strongly to the dorsal shoulder from TH 14 to SI 10 and distad to TH territory on the brachium and antebrachium. Teres minor trigger points send pain to TH 14, TH 13, and down the TH line toward TH 11. Referred pain from subscapularis trigger points covers the entire scapular region and centralizes over the dorsal shoulder from TH 14 to TH 13. The pain continues to TH 10 and then hops over the dorsal surface of the antebrachium to land at TH 4, spreading to the entire wrist with the dorsal aspect more intensely affected. Caudal deltoid trigger points extend from TH 14/SI 10 to TH 13, TH 12, and LI 11. Pain from coracobrachialis dysfunction may start at LU 2 but then migrate caudad toward LI 15 to focus heavily on the caudal brachium from TH 13 to TH 12, and TH 9 to TH 3.

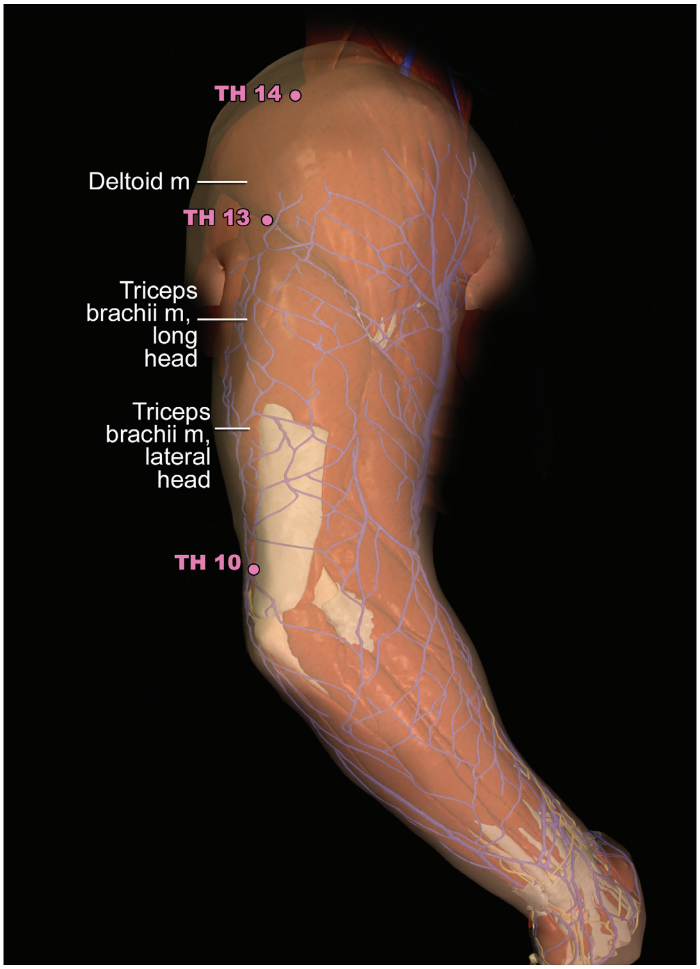
Nerves

- **Posterior brachial cutaneous nerve:** A branch of the radial nerve that supplies the skin on the posterior surface of the brachium.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium, including the triceps brachii muscle (lateral and medial heads). It divides into superficial and deep branches near the elbow.
- **Axillary nerve (C5, C6):** Innervates the deltoid muscle and teres minor muscle. Appears to also innervate, at least in a subset of the population, the long head of the triceps brachii muscle. Supplies the shoulder joint and the skin overlying the inferior deltoid region.
- **Intercostobrachial nerve (T2):** The ventral ramus of the 2nd thoracic spinal nerve divides into branches, the 2nd intercostal nerve (which is the larger of the two) and a smaller branch, which joins the brachial plexus. This smaller branch constitutes the lateral cutaneous branch of the 2nd intercostal nerve and is called the intercostobrachial nerve. It emerges from the 2nd intercostal space at the midaxillary line and penetrates the serratus anterior muscle to enter the brachial region, i.e., the axilla and arm. The floor of the axilla (i.e., the skin and its underlying subcutaneous tissue) receives its innervation from the intercostobrachial nerve. The intercostobrachial nerve communicates with the medial brachial cutaneous nerve to supply the posterior and medial surfaces of the arm. The intercostobrachial nerve may also communicate with the posterior brachial cutaneous nerve, a branch of the radial nerve.

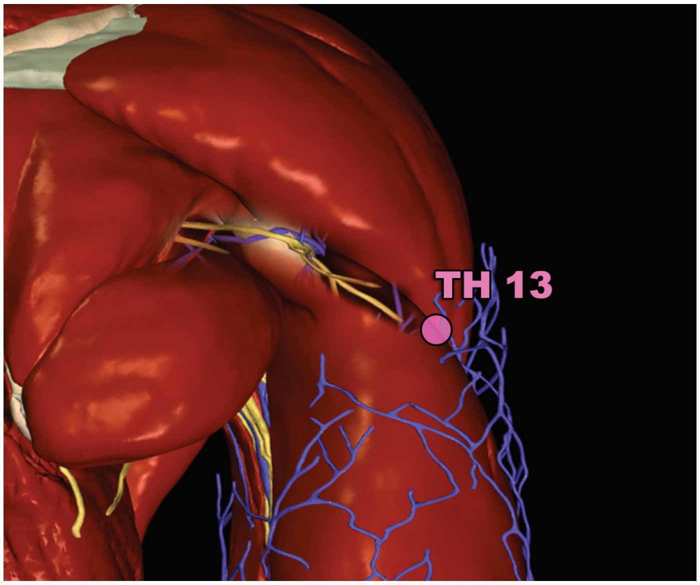
Clinical Relevance: Tension in the shoulder and proximal arm may compress one or more nerves traveling through various muscle layers to arrive at TH 13. As such, careful palpation of the entire region should help elucidate the source of pain and motor dysfunction that secondarily manifests. Deactivate relevant trigger points with acupuncture, relax the tissue further with soft tissue treatment, and follow up with laser therapy to aid in the restoration of appropriate blood flow and fluid drainage.

Vessels

- **Posterior humeral circumflex artery and vein:** Arise from the axillary vessels and exit along with the axillary nerve through the



Figures 10-34. TH 13 occupies the often-tender intersection of the long and lateral heads of the triceps brachii muscle, just distal to the deltoid. Hence its descriptive name, "Upper Arm Convergence".



Figures 10-35. This image takes a peek through a window created in the dorsal shoulder at the axillary nerve and posterior circumflex humeral vein (artery not shown), supplying the region around TH 13.

quadrangular space (bordered by the subscapularis/teres minor muscles, the teres major, the long head of the triceps brachii, and the surgical neck of the humerus). Supply and drain the teres minor, deltoid, and possibly portions of the triceps brachii muscle at TH 13.

- **Scapular circumflex artery and vein:** Travel through the anatomical triangular space, bordered by the teres major, teres minor, and long head of the triceps brachii muscles. Supply and drain each muscle.

Clinical Relevance: Both the quadrangular and triangular spaces create passageways that may compress the contents if muscle tension and fascial restriction grow too great. It behooves the physical medicine practitioner to alleviate such dysfunction when treating the dorsal shoulder in order to free the fascia and the neurovascular structures it surrounds.

Indications and Potential Point Combinations

- **Local pain:** TH 13 plus pertinent trigger points.
- **Shoulder arthritis:** TH 13, SI 10, LI 15, Jianqian (located midway between LI 15 and the anterior axillary crease).[2]

Figures 10-36. Applications for TH 13 pertain mostly to local pain in the triceps, deltoid, and scapular attachments. As indicated here, structures in the vicinity of TH 13 are mainly muscular.

TH 14

Jian Liao "Shoulder Crevice" or "Shoulder Bone-Hole"

Between the acromial and spinal parts of the deltoid muscle, in the caudal of two depressions appearing on either side of the acromion when the arm is abducted 90°. TH 14 lies in the depression caudal and distal to the acromion, whereas LI 15 is in the depression that lies cranial and distal to the acromion.

Connective Tissues

- **Subacromial bursa:** A synovial structure that facilitates gliding of proximal humerus under the coracoacromial arch.

Clinical Relevance: Subacromial impingement syndrome comprises a spectrum of problems ranging from subacromial bursitis to rotator cuff tears or tendon damage.[1] Shoulder problems have historically been "lumped" together as "bursitis" or "arthritis" without clear differentiation based on palpatory findings and ancillary examinations or diagnostic evaluation.

Wayward injections (e.g., vaccinations) into the deltoid muscle risk injury to the shoulder if fluids find themselves "shot" into the subacromial bursa, leading to a condition known as "shoulder injury related to vaccine administration (SIRVA).[2] Acupuncture and related techniques may aid in the resolution of resultant pain and inflammation.

Patients with adhesive capsulitis, or frozen shoulder, demonstrate overexpression of inflammatory cytokines in the subacromial bursa.[3] This argues for treatment with acupuncture and related techniques in order to modulate cytokine levels.

Muscles

- **Deltoid muscle:** The posterior part extends the arm and rotates it laterally. The anterior part flexes the arm and rotates it medially. The middle part abducts the arm.

Clinical Relevance: Caudal deltoid trigger points extend from TH 14/SI 10 to TH 13, TH 12, and LI 11. Trigger points in the long head of the triceps brachii muscle send telltale pain patterns along the entire TH channel, from TH 15 to TH 4. Myofascial dysfunction in the serratus posterior superior, latissimus dorsi, and infraspinatus muscles refer pain along the TH line toward the ring finger. A teres major trigger point issues pain strongly to the dorsal shoulder from TH 14 to SI 10 and distad to TH territory on the brachium and antebrachium. Teres minor trigger points send pain to TH 14, TH 13, and down the TH line toward TH 11. Referred pain from subscapularis trigger points covers the entire scapular region and centralizes over the dorsal shoulder from TH 14 to TH 13. The pain continues to TH 10 and then hops over the dorsal surface of the antebrachium to land at TH 4, spreading to the entire wrist with the dorsal aspect more intensely affected. Pain from coracobrachialis dysfunction may start at LU 2 but then migrate caudad toward LI 15 to focus heavily on the caudal brachium from TH 13 to TH 12, and TH 9 to TH 3.

Nerves

- **Axillary nerve (C5, C6):** Innervates the deltoid muscle and teres minor muscle. Also supplies the shoulder joint and the skin overlying the inferior deltoid region. Appears to also innervate, at least in a subset of the population, the long head of the triceps brachii muscle.
- **Lateral supraclavicular nerve (C3, C4):** Supplies the skin over the shoulder.
- **Superior lateral brachial cutaneous nerve (C5, C6):** Arises from the axillary nerve. Supplies the skin over the lower portion of the deltoid and the lateral part of the mid-arm.
- **Suprascapular nerve ((C4), C5, C6):** Supplies the supraspinatus and infraspinatus muscles. Also provides sensory branches to the caudal joint capsule of the shoulder. May provide cutaneous sensation to the skin at TH 14.[4,5]

Clinical Relevance: Tension in the shoulder and proximal arm may compress one or more nerves traveling through various muscle layers to arrive at TH 14. As such, careful palpation of the entire region should help elucidate the source of pain and motor dysfunction that secondarily manifests. Deactivate relevant trigger points with acupuncture, relax the tissue further with soft tissue treatment, and follow up with laser therapy to aid in the restoration of appropriate blood flow and fluid drainage.

Several orthopedic surgical procedures put the axillary nerve at risk.[6] Iatrogenic injury can occur following shoulder arthroscopy, thermal shrinkage of the shoulder, and plate fixation of the proximal humerus. The caudal branch of the axillary nerve associates closely with distal aspects of the glenoid and shoulder joint capsule.[7] This is where the nerve can suffer damage during capsular plication or thermal shrinkage. The superior lateral brachial cutaneous nerve arises from this caudal, or posterior, branch. The caudal deltoid more often receives innervation from the anterior or cranial branch of the axillary nerve, which may lead to injury during a posterior deltoid-splitting approach to the shoulder. In cases of nerve injury at or around TH 14, consider acupuncture and related techniques to revitalize the nerve(s) and accelerate soft tissue healing and return of function.

Vessels

- Posterior circumflex humeral artery and vein: Arises from the axillary vessels and passes through the quadrangular space with the axillary nerve. Anastomoses with the anterior circumflex humeral vessels to provide a circular anastomosis around the surgical neck of the humerus.

Clinical Relevance: Both the quadrangular and triangular spaces create passageways that may compress the contents if muscle tension and fascial restriction grow too great. It behooves the physical medicine practitioner to alleviate such dysfunction when treating the dorsal shoulder in order to free the fascia and the neurovascular structures it surrounds. Some of the vessels supplying the area around TH 14 must course through intersecting layers of myofascia. They may experience compression and result in insufficient circulation and drainage to and from the shoulder, respectively.

Indications and Potential Point Combinations

- **Shoulder pain from myofascial dysfunction or arthritis:** TH 14, LI 15; check regional musculature for trigger/acupuncture points that refer pain to the shoulder, such as those at or near SI 9, SI 10, SI 11, and SI 12.
- **Shoulder pain after stroke:**[8] TH 14, LI 15, LU 5, PC 3, GB 21, as well as additional areas that manifest restriction or tenderness. Add electroacupuncture and soft tissue manual therapy. Apply bilaterally.
- **Brachial plexus injury after birth:**[9] TH 14, LI 15, SI 9, LI 14, LI 13, LI 11, and other pertinent points depending on neurologic involvement.
- **Frozen shoulder:**[10] TH 14, LI 15, SI 9. Add heat or laser therapy to tender points.

TH 15

Tian Liao "Celestial Crevice" or "Celestial Bone-Hole"

Midway between GB 21 and SI 13, in a depression in the suprascapular fossa where the levator scapulae muscle inserts onto the superior angle of the scapula. Also located midway between the lateral limit of the acromion and GV 14; approximately 1 cun dorsocaudal to GB 21. See Figure 10-40 for placement.

Caution: Deep insertion may cause pneumothorax.

Muscles

- **Trapezius muscle:** Acts on the scapula to elevate, retract, and rotate it.
- **Supraspinatus muscle:** Helps the deltoid muscle abducts the arm and initiates the abduction movement. Acts as a rotator cuff muscle along with the infraspinatus, teres minor, and subscapularis muscles.
- **Levator scapulae muscle:** Tilts the glenoid cavity of the scapula inferiorly while rotating and elevating the scapula.

Clinical Relevance: Trigger points in the neck and shoulders commonly produce pain and morbidity in the human population.

A trigger point at TH 15 in the middle fibers of the trapezius issues pain toward the midline between C7 and T4. Levator scapulae trigger points in this same zone send pain signals in the angle between the neck and shoulder, down the medial border of the scapula, and toward the zone spanning TH 14 to SI 10.

A variety of interventions aid in alleviating trigger point pathology in the trapezius muscle, including manual pressure,[1] extracorporeal shock wave therapy,[2] acupuncture,[3] transcutaneous electrical point stimulation,[4] and laser therapy.[5,6]

Figure 10-42 reveals the depth of needle insertion required in a heavily muscled patient to reach the levator scapulae muscle at this level.

Nerves

- **Spinal nerves T1-T3:** Innervate the skin.
- **Spinal accessory nerve (also known as the spinal root of the accessory nerve, CN XI):** Provides motor innervation for the trapezius muscle.
- **Spinal nerves C2, C3, and C4:** Carry pain and proprioceptive information from the trapezius and sternocleidomastoid muscles.
- **Dorsal scapular nerve (C4, C5):** Innervates the levator scapulae and rhomboid major and minor muscles.

Clinical Relevance: Dorsal scapular nerve injury following trauma can present as a sharp pain in the shoulder that worsens when lifting heavy objects overhead.[7] Mechanism of injury includes traction or compression of the nerve through extended overhead work. Lifting a heavy box overhead places the dorsal scapular nerve at risk, as do occupational activities (for painters, electricians, dry wallers, etc.) involving raising the arms for long

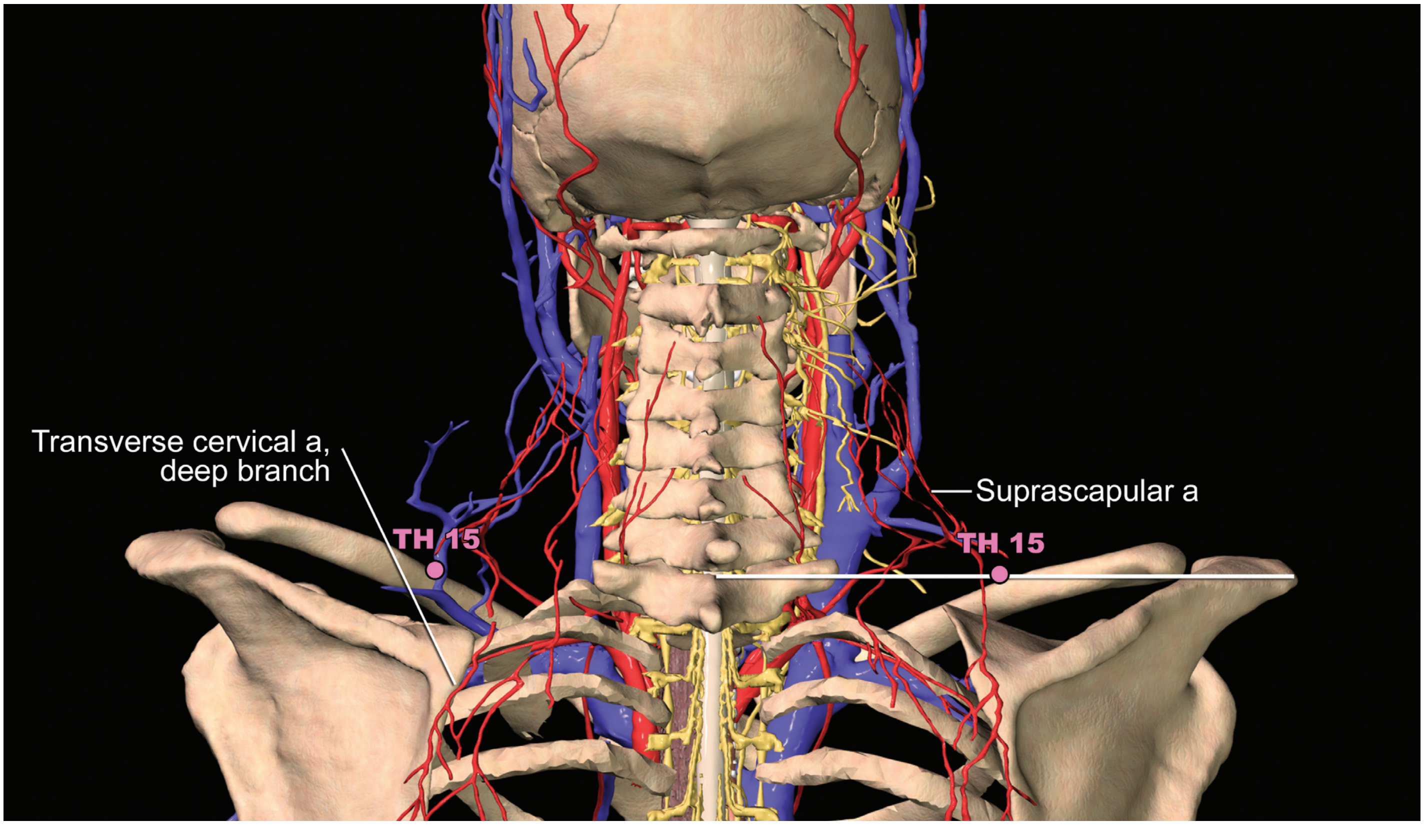

Figure 10-40. The bones forming the "Celestial Crevice" at TH 15 include the spine, the clavicle, and the 1st rib (absent on the right side in this individual). The white line on the right side of this image denotes the distance between GV 14 at the cervicothoracic junction and the tip of the acromion. TH 15 lands equidistant between them. In practice, one will palpate this region at the craniomedial angle of the scapula; doing so will likely reveal the presence of several trigger points.

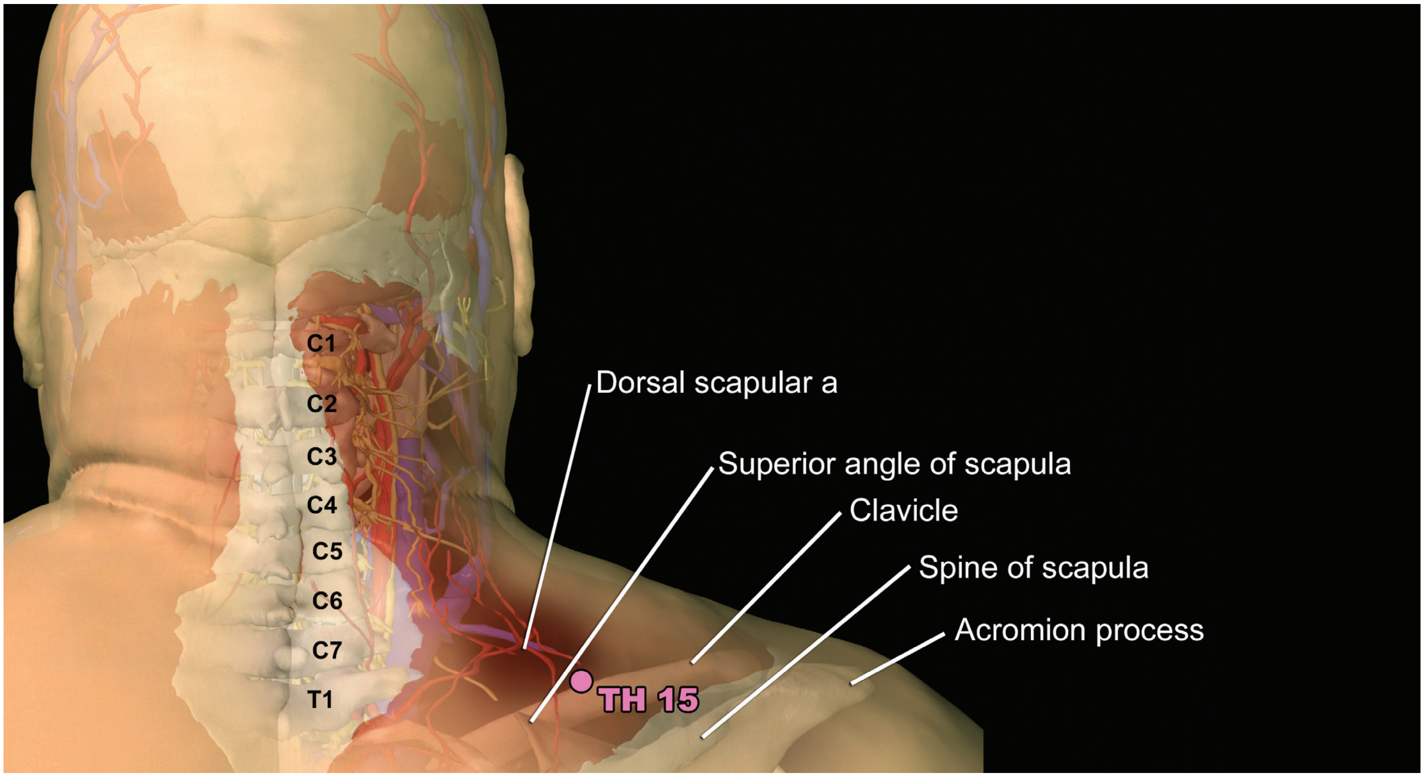

Figure 10-41. TH 15 figures prominently in trigger point treatments for neck and shoulder pain. Acupuncture, massage, and laser therapy aid in alleviating myofascial restriction as well as supporting proper blood flow.

periods of time. Hypertrophy of the middle scalene muscle can lead to dorsal scapular nerve entrapment as well. Pain becomes more severe with the addition of strain from compensatory or parascapular muscles or spasm in antagonists of the rhomboids and levator scapulae. On physical examination, the caudomedial border and caudal angle of the scapula become prominent ("winged"); the scapula as a whole moves laterad. Denervation or neuropathy of the dorsal scapular nerve causes the muscles it supplies to thin (levator scapulae and rhomboids) or atrophy; changes become visible on magnetic resonance imaging. Scapular winging as a result of dorsal scapular neuropathy is much less common than winging from long thoracic nerve injury (i.e., the nerve that supplies the serratus anterior muscle) or spinal accessory neuropathy (CN XI innervates the trapezius and sternocleidomastoid muscles). Long thoracic nerve palsy produces winging that worsens with arm forward elevation and pushing with outstretched arms. Spinal accessory nerve injury is accentuated by slowly lowering the arms from the arm forward-elevated position. Dorsal scapular nerve injury can be distinguished from C5 root lesion by the absence of abnormal electromyographic findings in other muscles supplied by C5. Rehabilitation includes range of motion, strengthening, and proprioceptive retraining as well as neuromodulation through acupuncture and related techniques. Entrapment of the dorsal scapular nerve due to compression by tension in the middle scalene muscle that it pierces may respond to massage and gentle stretching.

Vessels

- **Suprascapular artery:** Arises from the thyrocervical trunk (from the subclavian artery). Supplies the supraspinatus and infraspinatus muscles.
- **Suprascapular vein:** Accompanies the suprascapular artery. Empties into the external jugular vein.
- **Transverse cervical artery:** Arises from the thyrocervical trunk, along with the suprascapular artery, to supply the muscles in the posterior cervical triangle, the trapezius, and the medial scapular muscles.
- **Dorsal scapular artery:** This artery arises either from the transverse cervical or subclavian artery, runs deep to the levator scapulae muscle, and supplies the rhomboid muscles. The dorsal scapular artery joins with other arteries (the suprascapular and the subscapular, via the circumflex scapular) around the scapula to form arterial anastomoses. This collateral circulatory route provides another avenue of blood flow in the event of an interruption of blood supply through either the subclavian or axillary arteries. This interruption may result from ligation, in cases of a lacerated axillary or subclavian artery, or from vascular stenosis in the axillary artery secondary to atherosclerosis. In either situation, blood flow in the subscapular artery reverses direction, thereby allowing blood to reach the third part of the axillary artery. (The subscapular artery receives blood from the suprascapular, transverse cervical, and intercostal arteries via several anastomotic junctures.) See Figure 10-41 to view the dorsal scapular artery.

Clinical Relevance: The dorsal scapular artery travels intimately with the dorsal scapular nerve. As such, compression or traction injuries of the dorsal scapular nerve would conceivably affect the accompanying artery and vein in a similar fashion.

The transverse cervical artery crosses the phrenic nerve about 3 cm cranial to the clavicle at a right angle; hence the name "Red Cross Syndrome" when ischemic neuropraxia results from arterial compression of the nerve. While it stands anatomically apart from the well-defined prevertebral fascia, surgical,

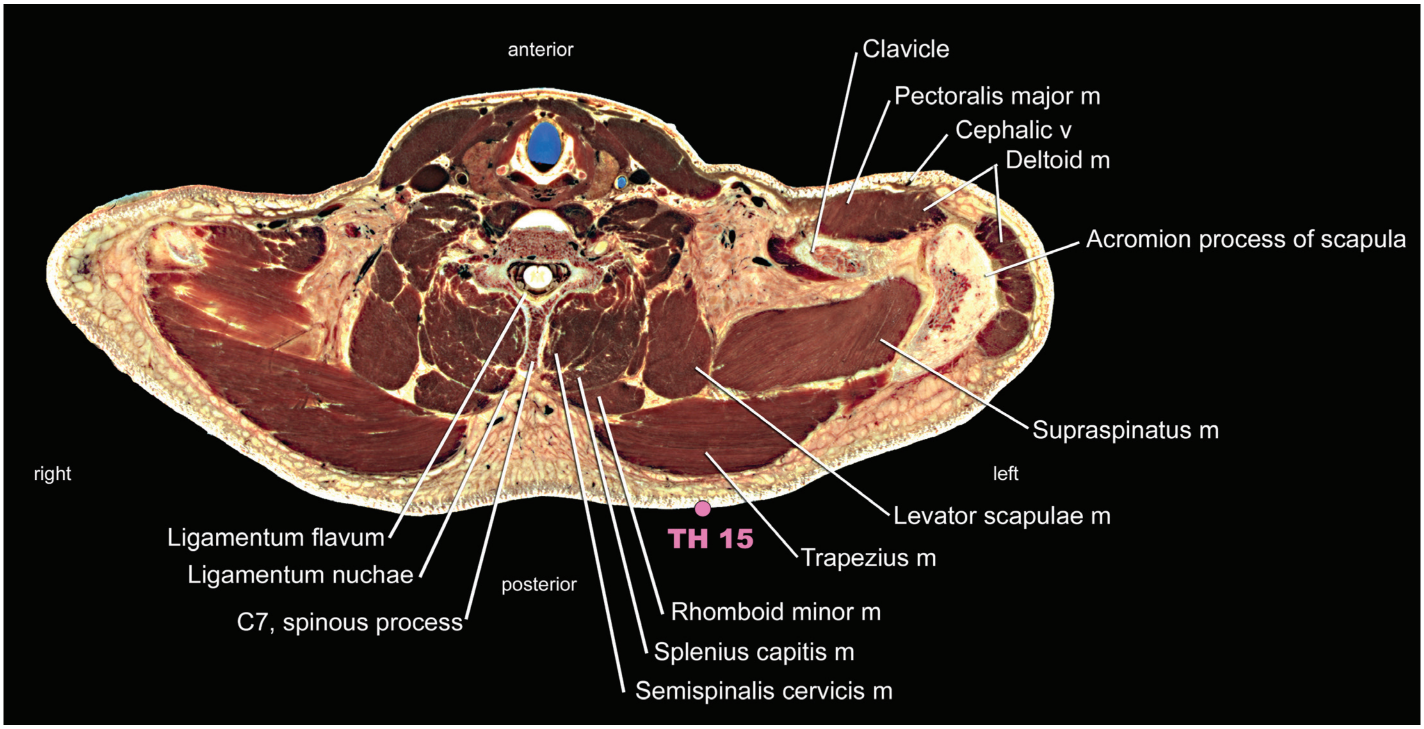

Figure 10-42. Trigger points treatable through TH 15 may reside in the trapezius, the “levator scapulae, or supraspinatus muscle, each accessible with needling, massage, or laser treatment to this region. Note the difference in muscle texture and color from the erector spinae group close to the center of the body and these larger, broader, movers of the shoulder joint.

anesthetic, or chiropractic procedures applied to the neck can stretch or transect the nerve. Trauma to the fascia and nerve may result in fibrosis and scarring in the area. Loss of tissue plane separation and adhesion of normally separate anatomical layers invites nerve compression and/or dysfunction.[8] Iatrogenic or traumatic injury to the cervical fascia may similarly impact the transverse cervical artery. Changes to the course and caliber of the artery from anatomical changes, preceding trauma, and/or inflammation can induce further compression of the phrenic nerve that lies deep to it. Phrenic nerve injury in the neck from transverse cervical artery is one source of diaphragm paralysis from peripheral causes.

Needling in the vicinity of TH 15 may augment blood flow through the vertebral and transverse cervical artery.[9] This may aid patients with cerebral blood flow insufficiency.

Acupuncture and related techniques alleviate myofascial restriction in the shoulder to allow better blood flow and improve tissue impair. Points to treat include TH 15, SI 14, SI 15, SI 16, ST 10, ST 11, and LI 18.

Indications and Potential Point Combinations

- **Neck or upper back stiffness or pain:** TH 15, for levator scapulae trigger points. Consider adding SI 16, SI 10, BL 13 through BL 17, and scalene trigger points.[10]

TH 16

Tian You "Celestial Window" or "Window of Heaven"

On the dorsal margin of the sternocleidomastoid muscle, just caudal to the mastoid process, level with the angle of the mandible, SI 17, and BL 10. Approximately 1 cun caudal to GB 12.

Muscles

- **Splenius capitis muscles:** The splenius muscles bend the head laterally and rotate it to the side of active muscles acting unilaterally; acting bilaterally, the splenius muscles extend the head and neck. Both right and left splenius capitis muscles function in concert to rotate the head and lift the chin.
- **Longissimus capitis muscle:** The longissimus muscles comprise the intermediate column of the intermediate layer of the intrinsic muscles of the back, the erector spinae.
- **Semispinalis capitis muscle:** The semispinalis capitis muscle resides deep to the splenius and medial to the longissimus cervicis and capitis. It functions to extend the head.[1]

Clinical Relevance: Referred pain patterns in muscles near TH 16 often flow along the TH trajectory.

Trigger points in neck, shoulder, and head muscles produce pain in a large segment of the population, in both office workers and manual laborers.[2]

Note in Figure 10-43 that TH 16 sits in the space between the trapezius and SCM. As such, while treatment applied to this area may impact myofascial dysfunction along the borders of these muscles, the main trigger point target of TH 16 is the splenius capitis muscle and those structures deep to the splenius. Pressure at TH 16 may activate trigger points in the splenius capitis and produce diffuse pain at the vertex, centered strongly over the ipsilateral parietal region.

Deep to the splenius capitiis lays the semispinalis capitis and longissimus capitis muscles, as revealed by the cross section in Figure 10-45. Myofascial pathology in the semispinalis sends pain signals to the occiput while trigger point dysfunction in the longissimus issues pain toward the mastoid region. Pain referred from the longissimus may extend caudad down the neck; it may also reach rostrad to the retro- or periorbital locations. This explains in part the pain that migraineurs report in the eye secondary to cervical somatic dysfunction.

Jaw clenching and teeth grinding co-activate muscles of the neck, including the splenius, SCM, trapezius, and levator scapulae. Sustained contraction leads to the typical and widespread myofascial dysfunction associated with TMJ and other stress-induced craniofacial disorders.[3] In turn, active trigger points disturb sleep, which further worsens pain and disability.[4]

Nerves

- **Lesser occipital nerve (C2):** Supplies the skin of the neck, and the scalp located dorsal and medial to the auricle.
- **Greater auricular nerve (C2, C3):** Supplies the skin over the

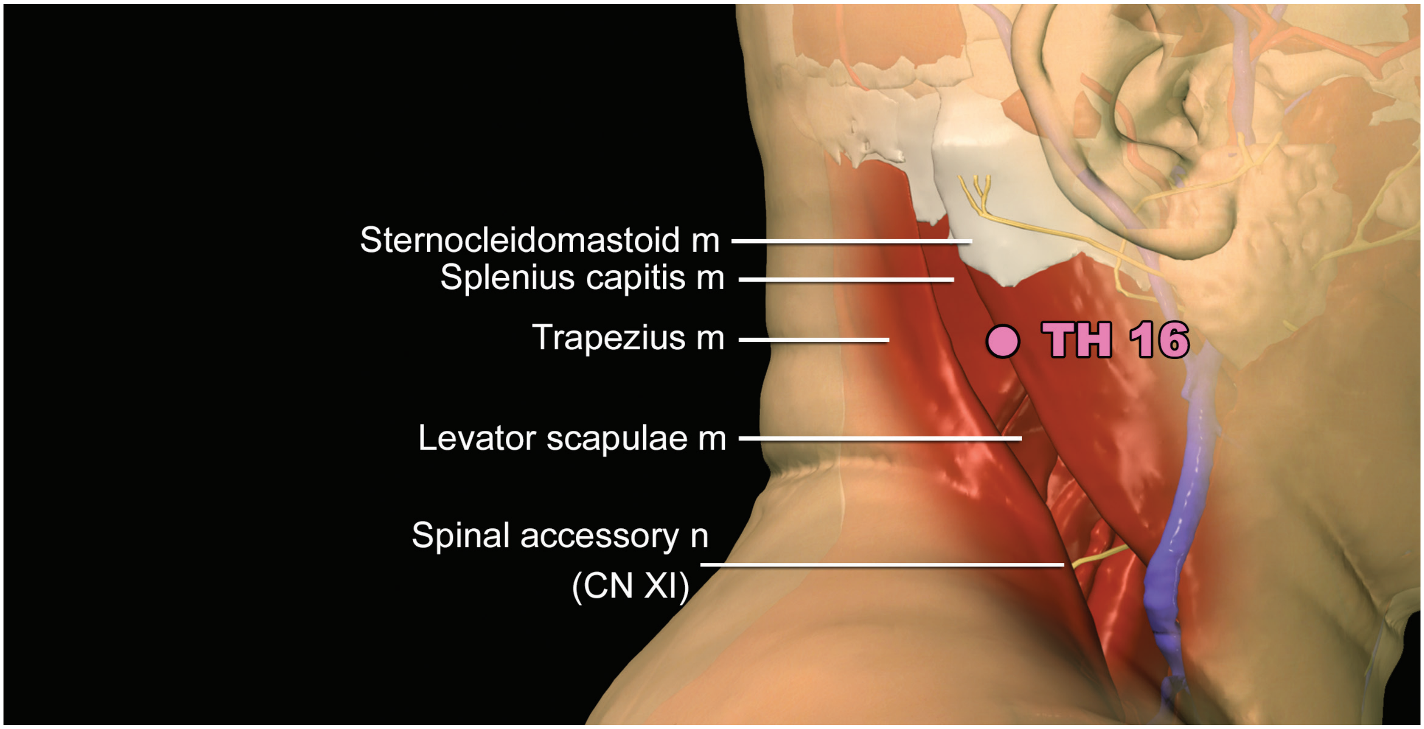

Figure 10-43. TH 16, as a "Celestial Window" sits at the juncture of the neck and head, creating a "window" or portal via the posterior (or dorsal) triangle of the neck. The borders of this triangle include the dorsal aspect of the sternocleidomastoid (SCM) muscle, the cranial border of the trapezius muscle, and the clavicle. The floor include the splenius capitis, levator scapulae, middle scalene, and posterior scalene muscles. The spinal accessory nerve (CN XI), shown in this image, supplies the (SCM) and superior part of the trapezius muscles that lie adjacent to TH 16. The cranial portion of the spinal accessory nerve joins with the vagus nerve and provides motor supply to striated muscle of the pharynx, larynx, soft palate, and esophagus, helping explain the applications for pharyngitis and dysphagia. Sensory fibers from C2, C3, and C4 meld with CN XI in this posterior triangle of the neck and supply pain and proprioception to the SCM and trapezius muscles.

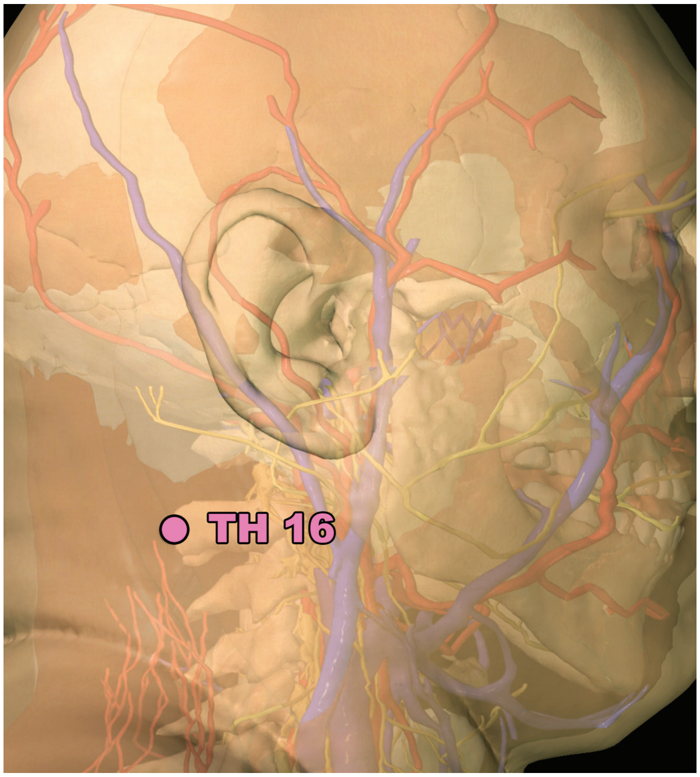

Figure 10-44. This semitransparent muscle layer reveals the relationship between TH 16 and the angle of the mandible.

parotid gland and the dorsal aspect of the auricle. Also supplies the skin between the angle of the mandible and the mastoid process.

- **C2-C6 spinal nerves, dorsal rami:** Innervate the splenius and erector spinae group of the neck.

Clinical Relevance: Cervical radiculopathy increases the prevalence of active myofascial trigger points in the neck.[5]

Peripheral nerve blocks of the greater occipital, lesser occipital, supratrochlear, supraorbital, and auriculotemporal nerves provide relief of headaches.[6] Neuromodulation by means of acupuncture and related techniques may involve similar nerves but also succeed in alleviating the motor component of area innervation that perpetuates the myofascial trigger points also involved in headache instigation.

Enlargement of superficial or deep occipital lymph nodes in the vicinity of TH 16 could promote nerve irritation.[7]

Vessels

- **External jugular vein:** The external jugular vein drains the side of the face and most of the scalp. It forms as a result of the union of the retromandibular vein and the dorsal auricular vein.
- **Occipital artery:** The occipital artery supplies the dorsal half of the scalp. It is a branch of the external carotid artery.
- **Occipital vein:** The occipital scalp region is drained by the occipital vein, which then drains into the suboccipital venous plexus.

Figure 10-45. This cross section illustrates the multiple muscles accessible to a needle entering the "Celestial Window" of TH 16. Trigger point pathology in these structures participates in producing referred pain patterns responsible for a spectrum of headache disorders.

Clinical Relevance: The occipital artery crosses the greater occipital nerve over 50% of the time.[8] Their interaction may range from a single intersection to a helical intertwining. Vascular pulsation in the artery can irritate the nerve, explaining how occipital neurovascular pathology triggers migraine and peripheral neurogenic headache.

Indications and Potential Point Combinations

- **Neck pain, stiffness, soreness that mimics discomfort from cervical lymphadenopathy, or torticollis, stemming from myofascial dysfunction in the SCM:** TH 16 plus other relevant and tender trigger points.
- **Sudden hearing loss or tinnitus related to trigger point(s) in the clavicular division of the SCM:** TH 16 plus trigger points associated with TMJ dysfunction; consider TH 21, SI 19, GB 2, TH or GB points around the year, active and latent SCM trigger points, GV 20.
- **Tension-type headache and referred pain from the SCM to the occiput, ear, eyebrow, zygomatic arch and cheek, chin, hyoid bone, and forehead from the sternal insertion:** TH 16, TH 17, TH 23, SI 18, SI 17, SI 16, LI 18, LI 17, BL 10, GV 20, tender trigger points.
- **Pharyngitis, dysphagia:** TH 16, CV 23, CV 22, ST 9, ST 10, ST 11, LI 4, LI 10, ST 36.
- **Unilateral autonomic dysfunction of the face, including ipsilateral sweating of the forehead, conjunctival hyperemia, tearing of the eye, rhinitis, narrowed palpebral fissure (resembles ptosis), possible diplopia with normal papillary light reflex, and visual disturbances, all related to trigger points in the sternal division of the SCM:** TH 16, TH 23, SI 19, GB 1, BL 2, Yintang, Taiyang, relevant trigger points.
- **Frontal headache, postural dizziness, carsick feeling, disturbed weight perception and equilibrium related to trigger points in the clavicular division of the SCM:** TH 16, relevant trigger points around the ear, temporal region, and SCM, ST 12, ST 13.

TH 17

Yi Feng "Wind Screen"

Immediately caudal to the root of the ear, beneath the earlobe, in the depression between the mastoid process and the ramus of the mandible. Just cranial to the palpable transverse process of C1. See Figure 10-46 for placement.

Needle cautiously. Several large vessels and delicate nerves reside at or near this point. See Figure 10-48 to learn more.

Glands

- **Parotid gland:** The largest of the three paired salivary glands. The facial nerve courses through the parotid gland, as does the retromandibular vein, and the external carotid artery (ECA) and its nerve plexus. The gland contains parotid lymph nodes both within the gland and on its tough fascial capsule, the parotid sheath. These lymph nodes drain lymphatic fluid from the forehead, lateral eyelids, temporal region, lateral auricular surface, anterior wall of the external acoustic meatus, and the middle ear.

Clinical Relevance: A number of tumors, both benign and malignant, as well as infections can enlarge the parotid gland. Tumor growth within the gland can induce facial pain (mediated by the trigeminal nerve) and facial nerve dysfunction, leading to paresis or paralysis of the muscles of facial expression. Remain cognizant of the possible presence of salivary gland tissue at or near TH 17. Avoid needling tumorous or other abnormal tissue.

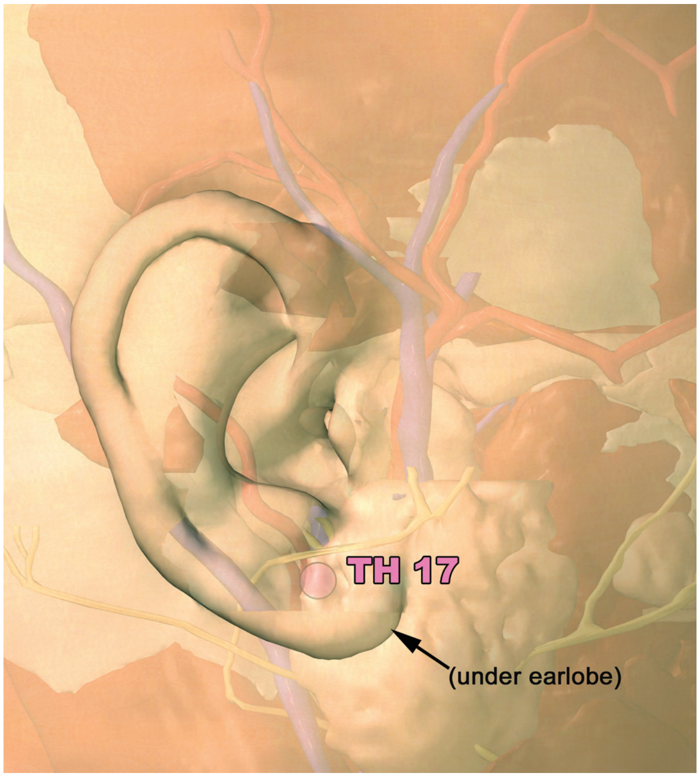

Figure 10-46. TH 17 sits coddled beneath the earlobe, tucked between the mastoid process and the ramus of the mandible. Its position close to the facial nerve trunk explains its clinical value for facial nerve dysfunction.

Nerves

- **Great auricular nerve (C2, C3):** Innervates the parotid sheath and the skin over the gland, along with the skin in the posterior aspect of the auricle and in the area between the angle of the mandible and the mastoid process. Its anterior branch communicates with the facial nerve (CN VII) inside the substance of the parotid gland. The posterior branch communicates with the lesser occipital nerve, the auricular branch of the vagus, and the posterior auricular branch of the facial nerve.
- **Facial nerve (CN VII):** The motor root of the facial nerve emerges from the skull at the stylomastoid foramen and courses through the parotid gland. It then divides into six terminal branches: the posterior auricular, temporal, zygomatic, buccal, mandibular, and cervical branches of the facial nerve. These nerve branches supply the muscles of facial expression via the motor root of the facial nerve. The other root of the facial nerve is smaller, called the intermediate nerve (or nervus intermedius). The intermediate nerve carries taste, parasympathetic, and somatic sensory fibers and travels in a distinct fascial sheath from the motor root. While the motor root emerges through the stylomastoid foramen, the intermediate nerve heads elsewhere, supplying visceral motor fibers to the lacrimal, submandibular, and sublingual glands and the mucous membranes of the nose, soft palate, and hard palate. The intermediate nerve also carries sensation from the skin of the concha (the deepest depression in the auricle) and a small area of skin behind the ear. It may assist the mandibular nerve (CN V_3) in supplying the wall of the acoustic meatus and external tympanic membrane. The intermediate nerve provides special sensory fibers to the anterior two-thirds of the tongue and palates to carry taste.

Clinical Relevance: The main clinical significance of TH 17 pertains to its relationship with the motor trunk of the facial nerve as it exits the skull. Upon leaving the brainstem at the ponto-medullary junction, the facial nerve enters the internal acoustic meatus and courses through the facial canal of the temporal bone. It exits the canal and skull through the stylomastoid foramen. Figure 10-48 exposes the intracranial and extracranial journey by means of this unusual glimpse through semi-transparent bone.

The facial nerve communicates with several other cranial nerves.[4] These include all three divisions of the trigeminal nerve (including branches of the auriculotemporal, buccal, mental, lingual, Infraorbital, zygomatic, and ophthalmic nerves). The facial nerve also communicates with branches of cranial nerves VIII, IX, and X. In the cervical region, it exhibits relationships with the great auricular, the greater and lesser occipital, and the transverse cervical nerves. These networks form circuits through which neuromodulation at TH 17 can produce myriad effects.

At TH 17, the most salient interconnection involves the facial nerve and the auriculotemporal nerve, a branch of the mandibular nerve (CN V_3) that supplies sensation to the lateral aspect of the head. The clinical significance of this connection means that needling or otherwise stimulating TH 17 may also neuromodulate the somatosensory root of the auriculotemporal nerve, which supplies sensation to the auricle, the external acoustic meatus, the outer aspect of the tympanic membrane, and skin over the temporal region. A few articular branches of the auriculotemporal nerve carry sensation from the temporomandibular joint, meaning that TH 17 may benefit patients with TMJ dysfunction and pain.

Figure 10-47. As the "Wind Screen", TH 17's indications strongly relate to its proximity to the facial nerve. In Chinese medicine, if "wind" metaphorically enters the cranium through this portal, it leads to "wind" type diseases, which in the head refer to neural dysfunction and viral infection. In this case, "wind" would affect the facial nerve. Ancient Chinese acupuncturists may have envisioned that twirling a needle at this site drove out wind that succeeded in traversing the screen. This figure displays numerous facial nerve branches fanning away from TH 17.

From a functional perspective, crosstalk between the trigeminal and facial nerves facilitates control over the muscles of facial expression. Proprioceptive input conveyed by trigeminal nerve branches carries information to the brain from the skin overlying these muscles. Trigeminal nerve linkages with these muscles occur at motor endplates. This interconnection appears to offer an alternate pathway for impulses from the motor cortex to reach facial muscles in the event of facial nerve injury, providing a substitute route for motor supply to reach otherwise denervated muscles of facial expression.

Another portion of the auriculotemporal nerve, its parasympathetic or "inferior" root, carries postganglionic fibers to the parotid gland. These preganglionic secretomotor fibers originate from the glossopharyngeal nerve (CN IX) and emerge as the lesser petrosal nerve. Fibers from this nerve synapse in the otic ganglion; from here, the inferior, parasympathetic root of the auriculotemporal nerve emerges. Secretomotor fibers hitchhike with the auriculotemporal nerve. They will depart from the somatosensory portion to innervate the parotid gland. From here, the auriculotemporal nerve will ferry supply sensation to the temporal region.

The vast amount of neural networking between the facial nerve and its neighbors explains why certain syndromes of facial pain improved when surgeons intentionally sever facial nerve branches as a means to treat conditions such as pterygopalatine neuralgia, a neurologic disorder involving both facial pain and autonomic dysfunction, in the eye.[5] Even if in some cases the neuralgia responds to greater petrosal nerve neurectomy, it would seem that neuromodulation through acupuncture and related techniques should be tried long before any nerves become further damaged, whether due to the disease or an iatrogenic misstep.

The facial nerve connects to cranial nerves VIII, IX, X, IX, and XII. CN VIII, the vestibulocochlear nerve, comes into contact with the facial inside the internal acoustic meatus. Connections include the nervus intermedius and the vestibular nerve as well as fibers of the genu of the facial nerve and the vestibular ganglion. Thus, when for patients with vertigo, TH 17 and nearby points (GB 12, GB 20, TH 20, TH 21 may offer an indirect conduit through which to induce neuromodulation to the vestibulocochlear nerve.

Note, too, that the stylomastoid foramen resides near the jugular foramen. The latter exit site transmits CN IX, X, XI, and XII along with the internal jugular vein. All these structures passing through this narrow canal relate closely to the transverse process of C1 (the atlas) and the styloid process. Thus, treatment applied to the vicinity of TH 17 may neuromodulate one or more of these four most caudal cranial nerves by dint of their proximity to the point. The styloid process of the temporal bone, labeled in Figure 10-48, serves as a landmark for the glossopharyngeal nerve[6] along with the transverse process of C!, evident in Figure 10-47.

The glossopharyngeal nerve makes several connections with the facial. These include twigs linking the two not only within the facial canal but elsewhere as well. At the base of the skull, anastomoses take place between the facial and glossopharyngeal nerves through an ascending branch off of the stylopharyngeal branches from CN IX and a stylohyoid branch of CN VII. The nature of the anastomosis can range from a single neural connection to a delicate neural plexus. A small branch from the digastric branch of the facial nerve can also communicate with the glossopharyngeal.

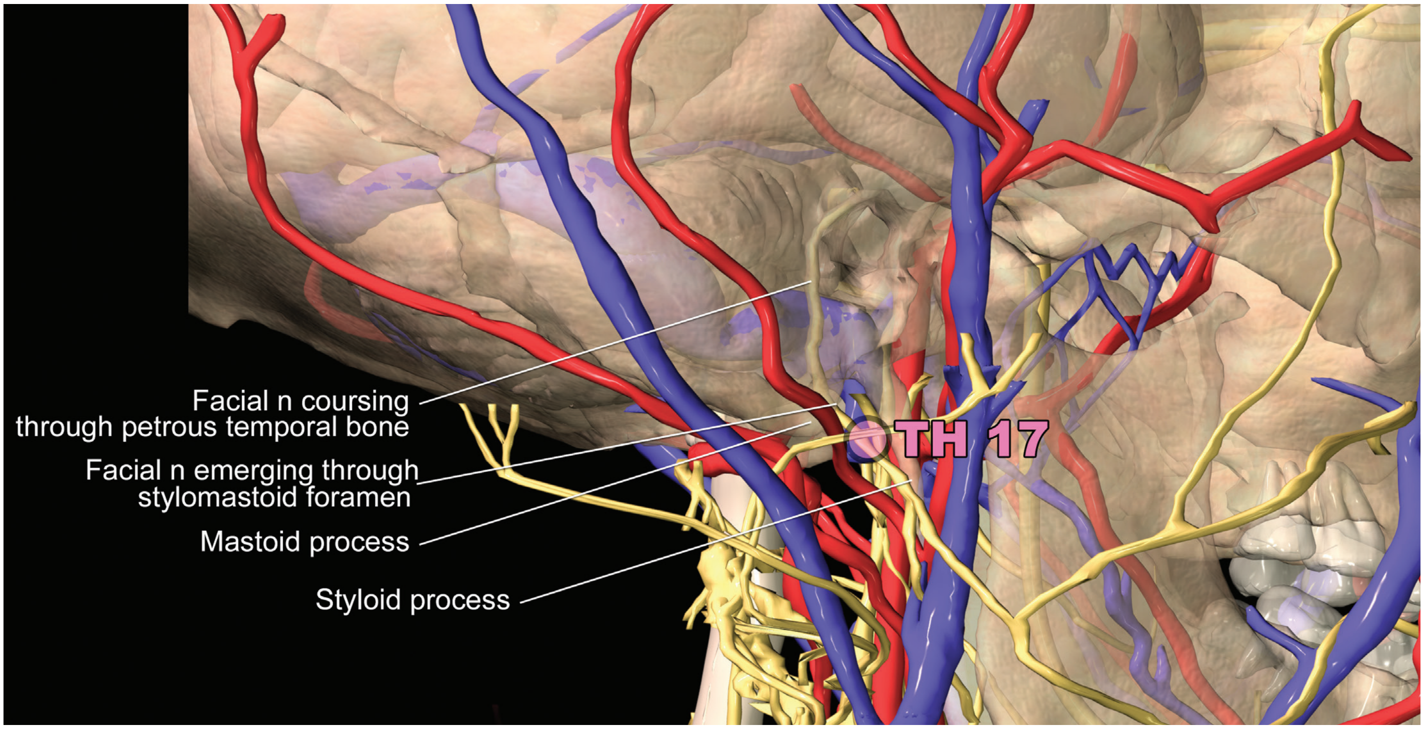

Figure 10-48. This see-through skull image allows visualization of cranial nerves inside the head. These usually hidden structures include the optic nerve heading toward the orbit, the mandibular nerve coursing toward the chin inside the mandible, and the facial nerve emerging through the stylomastoid foramen. Here, the nerve has just made its way through the petrous portion of the temporal bone. TH 17 catches the facial nerve trunk after it exits the skull, destined for the muscles of facial expression. This depiction also reveals the rich neurovascular traffic present at TH 17.

This reinforces the clinical potential of treatment at TH 17 to neuromodulate a variety of craniofacial functions.

Vagal crosstalk occurs between the facial nerve at TH 17, nearby TH points, and the ear. This takes place by means of communicating fibers from the posterior auricular branch of the facial nerve and Arnold's nerve, also known as the auricular branch of the vagus. Laser, massage therapy, and acupuncture can thus neuromodulate the parasympathetic limb of the autonomic nervous system via this nexus.

As discussed above (see great auricular nerve description), the facial nerve connects with the great auricular nerve from the cervical plexus. The facial nerve may therefore offer a conduit by which to enhance neuromodulation of the greater and lesser occipital nerves, the transverse cervical nerve, and sympathetic fibers exiting the superior cervical ganglion, as connections exist between the facial nerve and each of these structures. This may explain why patients with headache pain and autonomic dysregulation of the head and neck benefit strongly from neuromodulation with acupuncture and related techniques.

Vessels

- **External jugular vein and its tributaries:** The external jugular vein drains the side of the face and most of the scalp. It forms as a result of the union of the retromandibular vein and the posterior auricular vein.
- **Internal jugular vein:** This vein drains blood from the brain, cervical visceral, deep cervical muscles, and the face. It begins at the jugular foramen located in the posterior cranial fossa as a direct continuation of the sigmoid sinus.
- **Posterior auricular artery:** This small branch of the external carotid artery ascends between the external acoustic meatus and the mastoid process. Its distribution includes the nearby muscles, parotid gland, facial nerve, auricle, scalp, and structures in the temporal bone.
- **Posterior auricular vein:** The posterior auricular vein not only drains the scalp posterior to the auricle, but it also often receives a mastoid emissary vein from the sigmoid sinus, one of the dural venous sinuses.
- **External carotid artery:** This artery branches into the maxillary and superficial temporal arteries. It supplies mainly extracranial structures, except for the middle meningeal artery (which branches off of the maxillary artery), the largest of the meningeal arteries.

Clinical Relevance: Ordinarily, blood that drains from the brain empties into the posterior fossa and, from there, into the internal jugular veins or vertebral venous system.[7] The external jugular veins ordinarily drain the viscerocranium (i.e., the face) and the neurocranium (i.e., the part of the skull that houses the brain) but much less commonly receive cerebral venous drainage. In some cases, however, cerebral drainage connects with the external jugular venous system by means of connections between middle cerebral veins, the pterygoid plexus, cavernous sinus, and/or emissary veins from the middle cranial fossa.

In other cases, the rostral end of the transverse sinus and veins of the temporal fossa connect through a petrosquamosal sinus. This sinus starts where the transverse and sigmoid sinuses meet, located at the juncture of the petrous and squamous portions of the temporal bone. In most human adults, the petrosquamosal sinus regresses into an embryonic venous remnant or disappears entirely. Its main clinical significance pertains to the hemorrhagic hazard it poses with respect to surgical procedures

Figure 10-49. TH 17 constitutes one of the few points in the acupuncture matrix that does not incorporate local trigger point deactivation as an indication. This cross section illustrates the presence of bone, rather than muscle, deep to the site, more clearly shown on the left side of the head (right side of the image).

of the mastoid region. For a medical acupuncturist, vascular aberrancies in the temporal region should be considered as potential sources of tinnitus. While acupuncture and related techniques will not alter venous connections within the skull, neuromodulation and myofascial work may alleviate intracranial pressure and venous flow by means of extracranial treatment (with acupuncture and manual therapy) as well as transcranial laser therapy. The transverse and sigmoid cerebral venous sinuses appear through the semi-translucent skull in Figure 10-48.

For the more common condition of migraine, medical acupuncturists should remain vigilant to the role extracranial (scalp) arteries can play in headache generation.[8] Myofascial trigger points and associated structural dysfunction compress not only nerves and but also vessels, making both unhappy and irritable. Afferents from irritated nerve produce algogenic peptides following compressive forces. Treatment with cryotherapy and/or other physical medicine approaches such as acupuncture, massage, and laser therapy may address neuropathic pain from these sources.

Indications and Potential Point Combinations

- **Ear problems, deafness:** TH 17, SI 19, trigger points in the SCM.
- **Ear pain:** Consider source and location of pain; i.e., whether the otalgia has an otologic etiology or arose as a result of referred pain.1 TH 17, TH 16, TH 20 for local pain, plus appropriate points related to pain generator. For orofacial pain referring to the ear, consider myofascial trigger points in the masseter (ST 6), ST 5, and SCM trigger points. For TMJ pain, consider adding SI 18, SI 19, TH 21, GB 2.
- **TMJ pain or dysfunction:** TH 17, TH 16, LI 18, SI 19, GB 21, GB 20.
- **Facial nerve injury or paralysis:** TH 17 as the central and most important stimulation target. Add points according to the nerve branch(es) affected (selecting points along their axons) and their muscular destinations.[9]
- **Toothache:** TH 17, temporalis trigger points that may refer to the teeth, including TH 20, TH 21, TH 22. For odontologic sources of odontalgia, add LI 4, LU 7.
- **Blepharospasm:** TH 17, GB 1, GB 2, TH 23, Yintang, BL 2. Add acupressure at ST 2.

Evidence-Based Applications

- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[2]

- Acupuncture at LI 4, ST 6, ST 7, and TH 17 was superior to placebo for the prevention of **postoperative dental pain.**[3]
- **Peripheral facial nerve paralysis** treatment based on randomized controlled trials, includes TH 17, ST 2, ST 4, ST 6, ST 7, LI 4, LI 20, GB 14, GB 20, GV 26, Yuyao (mid-eyebrow), SI 18, and CV 24.[10]

TH 18

Qi Mai "Spasm Vessel", "Convulsion Vessel", "Tugging Vessel"

On the center of the mastoid process, in a small depression that lies at the junction of the middle and lower thirds of a curve that connects TH 17 and TH 20 and follows the outline of the helix.

Muscles

- **Posterior auricular muscle:** The posterior auricular muscle wiggles the ear.

Clinical Relevance: TH 18 abuts the posterior, or caudal auricular muscle. As such, neuromodulation at this site may benefit myofascial pathology not only in this muscle but fibers from the attachment of the sternocleidomastoid (SCM) muscle as well, shown in Figure 10-51.

Nerves

- **Posterior auricular nerve (CN VII):** A branch of CN VII, the posterior auricular nerve supplies the posterior auricular muscle and the occipital belly of the occipitofrontalis, or epicranius, muscle.
- **Intermediate nerve, or nervus intermedius (CN VII):** The cutaneous sensory component of CN VII, named the "intermediate" nerve mainly for its position between the cerebellopontine angle and the internal auditory canal.[1] However, it also lies between the motor fibers of the facial nerve and the eighth cranial nerve. Furthermore it. The intermediate nerve carries taste, parasympathetic, and somatic sensory fibers and travels in a distinct fascial sheath from the motor root. While the motor root emerges through the stylomastoid foramen, the intermediate nerve heads elsewhere, supplying visceral motor fibers to the lacrimal, submandibular, and sublingual glands and the mucous membranes of the nose, soft palate, and hard palate. The intermediate nerve also carries sensation from the skin of the concha (which is the deepest depression in the auricle) and a small area of skin behind the ear, including TH 18. It will, at times, assist the mandibular nerve (CN V_3) in supplying the wall of the acoustic meatus and external tympanic membrane. The intermediate nerve provides special sensory fibers to the anterior two-thirds of the tongue and palates to carry taste. The cell bodies of the sensory fibers comprising the intermediate nerve reside in the geniculate ganglion, housed within the petrous temporal bone. Sensory impulses travel to the brainstem by through the intermediate nerve and descend in the spinal tract of the trigeminal nerve; fibers from the intermediate nerve synapse in the spinal portion of the trigeminal nucleus in the rostral medulla.[2]
- **Great auricular nerve (C2, C3), posterior branch:** This nerve provides sensation to the skin over the parotid gland, the posterior portion of the auricle, and the area of skin between the angle of the mandible and the mastoid process. Its anterior branch communicates with the facial nerve (CN VII) inside the substance of the parotid gland. The posterior branch communicates with the lesser occipital nerve, the auricular branch of the vagus, and the posterior auricular branch of the facial nerve.
- **Lesser occipital nerve (C2):** This nerve provides innervation to the skin of the neck and the scalp lying posterior and superior to the auricle.

Clinical Relevance: The nervus intermedius (or intermediate nerve) has received substantial attention as a major neural culprit causing cluster headache. The parasympathetic connec-

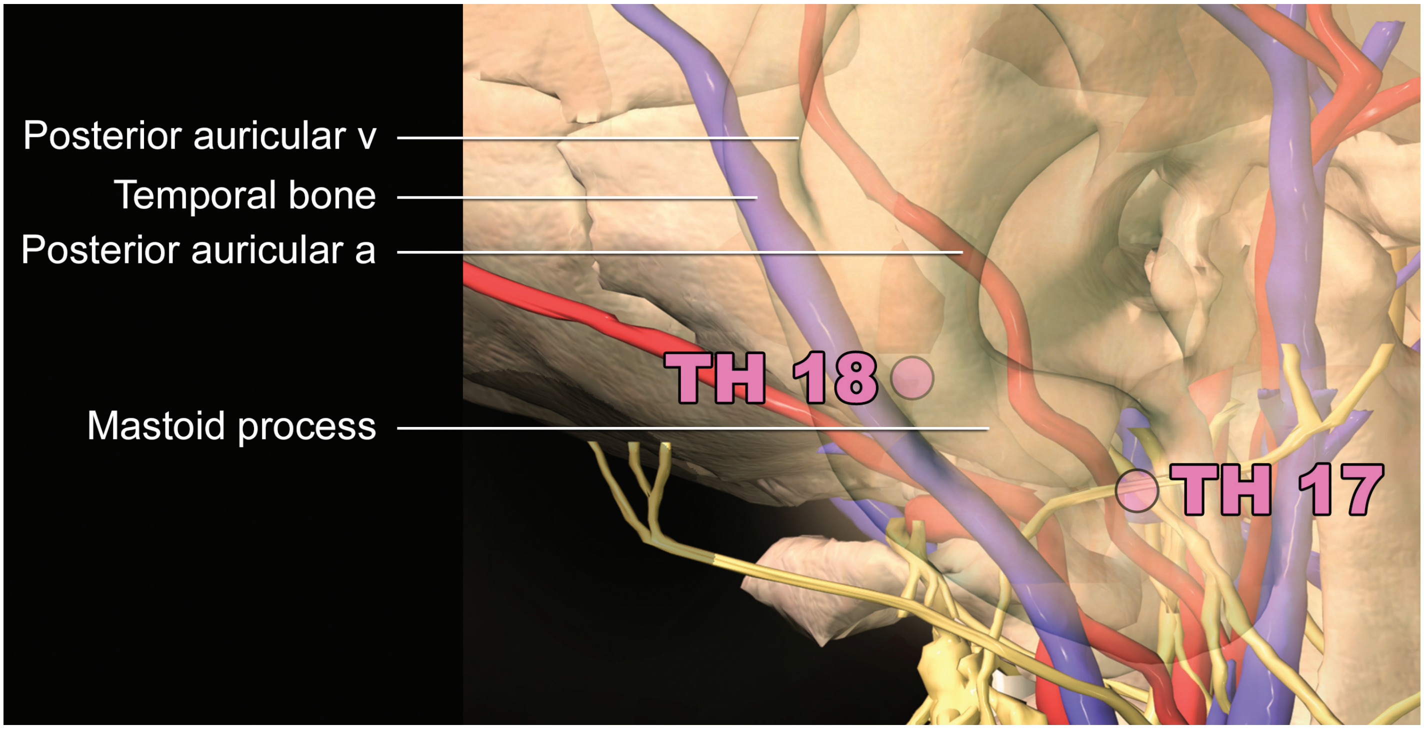

Figure 10-50. As the TH line travels up and around the ear where it attaches to the head, it follows the posterior auricular artery, the vessel alluded to by the term "Spasm Vessel" for TH 18. This suggests that vascular headaches and vasospastic diseases, likely even vasculitides, date back to ancient China.

tions made by the nervus intermedius explain the tearing and redness in the ipsilateral eye as well as nasal congestion and rhinorrhea. However, the migraine-like pain relates to vasodilatory stimuli affecting the internal carotid artery, its medium-sized branches, and the pial arteries. (On the head, vessels dilate after parasympathetic nervous system activation rather than inhibition of vasoconstrictor sympathetic tone.) As the internal carotid artery swells, the periarterial sympathetic nerves (nervi vasorum) supplying the artery can become compressed between the artery and the bony carotid canal. A partial Horner's syndrome may result.[11]

In addition to cluster headache, a neuropathic nervus intermedius can cause deep ear pain.[12] This needs to be differentiated from glossopharyngeal and trigeminal neuralgic sources in order to successfully isolate the etiology.[13] Infections of the middle ear can irritate the nerve due to its position within or near the tympanic cavity.[14] Geniculate neuralgia, or irritation of the nervus intermedius is often idiopathic. It leads to brief paroxysms of stabbing pain deep within the auditory canal.[15] Pain lasts from seconds to minutes; a trigger locus in the caudal wall of the auditory canal points to involvement of the nervus intermedius. While one approach to treat geniculate neuralgia includes transection, a nonsurgical method of neuromodulation by means of acupuncture, massage, and laser applied to the caudal auricular zone at TH 18 and TH 19 should be tried first.

Nervus intermedius dysfunction occurs in almost one quarter of patients undergoing modern Gamma Knife surgery for vestibular Schwannoma.[16] The nerve carries no perineurium within the skull, only a thin layer arachnoid membrane. Thus, it can more readily suffer mechanical damage than other portions of the facial nerve. Radiosurgery thus risks injuring this portion of the facial nerve and causing disturbances in lacrimation, salivation, nasal secretion, and/or taste. Patients reporting this unfortunate result of radiosurgery may benefit from acupuncture. Direct treatment to TH 18, TH 19, and the groove behind the ear, i.e., cutaneous sites of nervus intermedius innervation, with acupuncture, laser, and/or massage may aid in reducing the neuropathic activity of this nerve.

Extracranial nerves of the caudal portion of the head such as the posterior auricular nerve or lesser occipital undergo entrapment and compression as a result of myofascial restriction in the SCM muscle or occipitofrontalis, producing a variety of headache patterns.[17]

One of the risks of having a facelift performed involves nerve damage; injury to the great auricular nerve happens in about 7% of patients.[18] This nerve courses over the mid-body of the SCM where it bifurcates into anterior and posterior (or rostral and caudal) branches and its terminal arborization. Rhytidectomy surgery involving revision of cervical folds may damage the great auricular nerve and cause loss of sensation caudal to the ear at TH 18 and TH 19. Nerve stimulation in this zone may facilitate return of sensation, depending on the type of nerve damage induced. Include TH 16 and LI 18.

Vessels

- **Posterior auricular artery:** This small branch of the external carotid artery ascends between the external acoustic meatus and the mastoid process. Its distribution includes the nearby muscles, parotid gland, facial nerve, auricle, scalp, and structures in the temporal bone.
- **Posterior auricular vein:** The posterior auricular vein not only drains the scalp posterior to the auricle, but it also often receives a mastoid emissary vein from the sigmoid sinus, which is one of the dural venous sinuses.
- **Mastoid emissary vein:** Emissary veins communicate between the dural venous sinuses and the external skull veins. The mastoid foramen transmits the mastoid emissary vein, connecting directly to the sigmoid sinus within the skull and a caudal auricular plexus wherein the posterior auricular vein communicates with tributaries of the occipital and superficial temporal veins.

Clinical Relevance: True to its name as "spasm vessel" or "tugging vessel", the posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization represents one alternative to pharmacotherapy,[19] it seems unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear, inhabited by TH 18 and TH 19. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites. The spatial relationships between TH 18, the posterior auricular vein, the mastoid bone (housing mastoid air cells), and the sigmoid sinus show clearly in Figure 10-52.

Indications and Potential Point Combinations

- **Ear problems:** Pain, hearing loss, tinnitus: TH 18, TH 17, TH 20, TH 21, local temporalis trigger points bilaterally. Consider the neuroanatomical connections between somatic afferents, the descending spinal trigeminal tract, and the solitary tract that can complicate the diagnosis in cases of ear pain. Nerves involved include the auriculotemporal nerve (CN V), posterior auricular nerve (CN VII), anastomotic branches to CN IX, the auricular branch of the vagus nerve (CN X), and the great auricular nerve from C2 and C3.7 The pain of nervus intermedius otalgia can elude diagnosis; it causes a severe, piercing, shock-like pain deep within the ear.[8]
- **Dizziness:** TH 18, TH 19, SCM trigger points, LR 3, GV 20. Laser, if appropriate, TH points around the ear and GB 20.
- **Motion sickness:** Neuromodulation applied to TH 18, PC 6, and CV 8.[20]

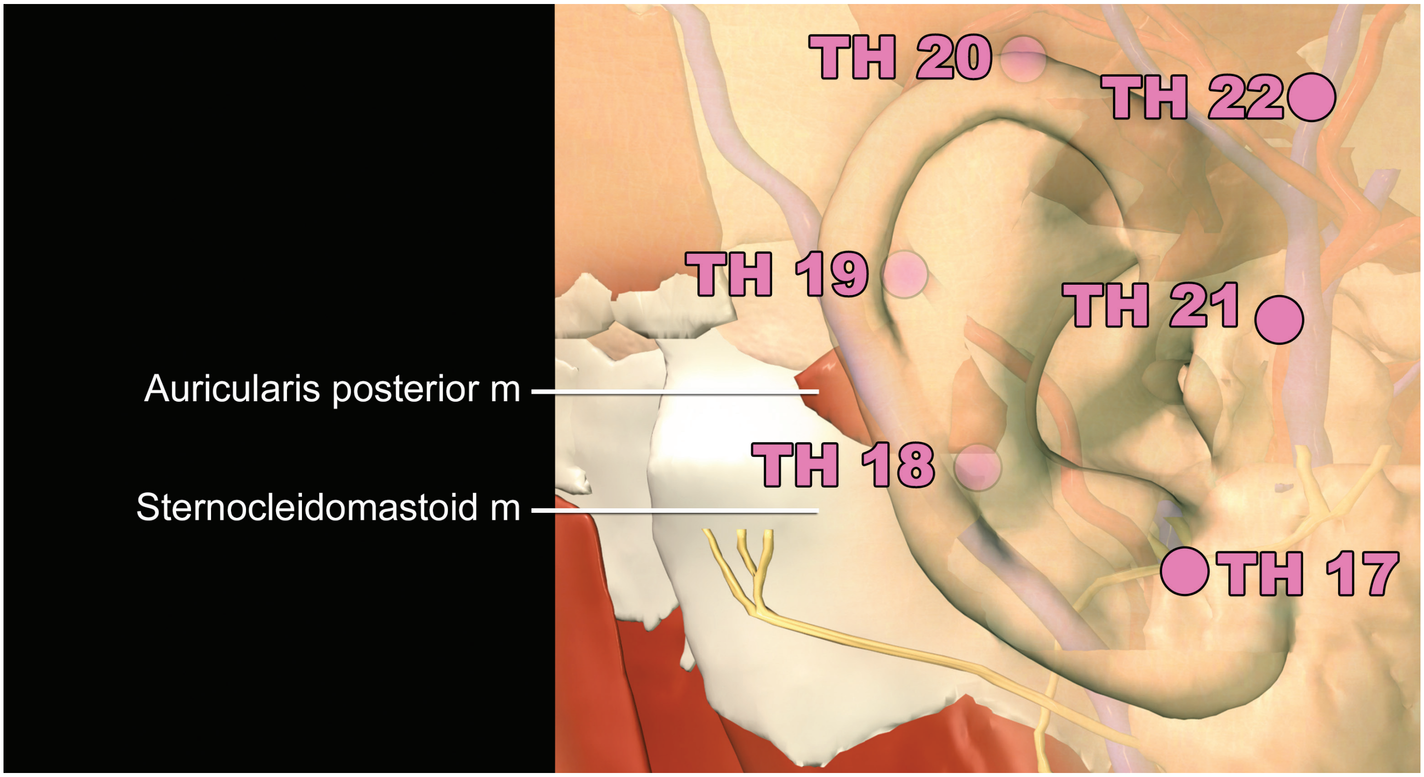

Figure 10-51. Myofascial restriction in the posterior auricular and SCM muscles, both depicted here, can issue pain in the vicinity of TH 18.[21]

- **Headache:** TH 18, GV 20, BL 10, relevant trigger points depending on the distribution of head pain. Consider adding the "Groove Behind the Ear Point" for cluster headache.
- **Seizures:** TH 18, ST 36, GV 20, Yintang (GV 24.5), LR 3.
- **Hypertension:** TH 18, LI 5, ST 36, LR 3, GV 20, "Groove Behind the Ear Point".[9]
- **Nervus intermedius neuralgia (patients feel an intense, stabbing pain deep within the canal of the ear):**[10] TH 18, TH 17, GB 12, "Groove Behind the Ear" point.

Figure 10-52. The intermediate nerve, or nervus intermedius, conveys general sensory information in the small area behind the ear, near TH 18, as well as the skin in the vicinity of the concha of the external ear. Crosstalk between this facial nerve branch and the vagus nerve provides the neuroanatomic rationale for selecting TH 18 and the nearby "Groove Behind the Ear" point in hypertensive patients with the goal of reducing blood pressure.

TH 19

Lu Xi "Skull Rest" or "Skull's Breath"

Behind the ear, in a depression at the junction of the upper and middle thirds of a curve connecting TH 17 and TH 20, following the outline of the helix.

Muscles

- **Posterior auricular muscle:** The posterior auricular muscle wiggles the ear. (See Figure 10-51).

Clinical Relevance: Some causes of otalgia may result from myofascial dysfunction in the posterior auricular muscle. Pain may also arise from neuropathic nerves in the vicinity or trigger points in the sternocleidomastoid (SCM) muscle. Neuromodulation at TH 19 and TH 18 can provide relief in many cases.

Nerves

- **Posterior auricular nerve (CN VII):** A branch of CV VII, the posterior auricular nerve supplies the posterior auricular muscle and the occipital belly of the occipitofrontalis, or epicranius, muscle.
- **Lesser occipital nerve (C2):** This nerve provides innervation to the skin of the neck and the scalp lying posterior and superior to the auricle.
- **Great auricular nerve (C2, C3), posterior branch:** This nerve provides sensation to the skin over the parotid gland, the posterior portion of the auricle, and the area of skin between the angle of the mandible and the mastoid process. Its anterior branch communicates with the facial nerve (CN VII) inside the substance of the parotid gland. The posterior branch communicates with the lesser occipital nerve, the auricular branch of the vagus, and the posterior auricular branch of the facial nerve.

Clinical Relevance: Extracranial nerves of the caudal portion of the head such as the posterior auricular nerve or lesser occipital undergo entrapment and compression as a result of myofascial restriction in the SCM muscle or occipitofrontalis, producing a variety of headache patterns.[1]

One of the risks of having a facelift performed involves nerve damage; injury to the great auricular nerve happens in about 7% of patients.[2] This nerve courses over the mid-body of the SCM where it bifurcates into anterior and posterior (or rostral and caudal) branches and its terminal arborization. Rhytidectomy surgery involving revision of cervical folds may damage the great auricular nerve and cause loss of sensation caudal to the ear at TH 18 and TH 19. Nerve stimulation in this zone may facilitate return of sensation, depending on the type of nerve damage induced. Include TH 16 and LI 18.

Vessels

- **Posterior auricular artery:** This small branch of the external carotid artery ascends between the external acoustic meatus and the mastoid process. Its distribution includes the nearby

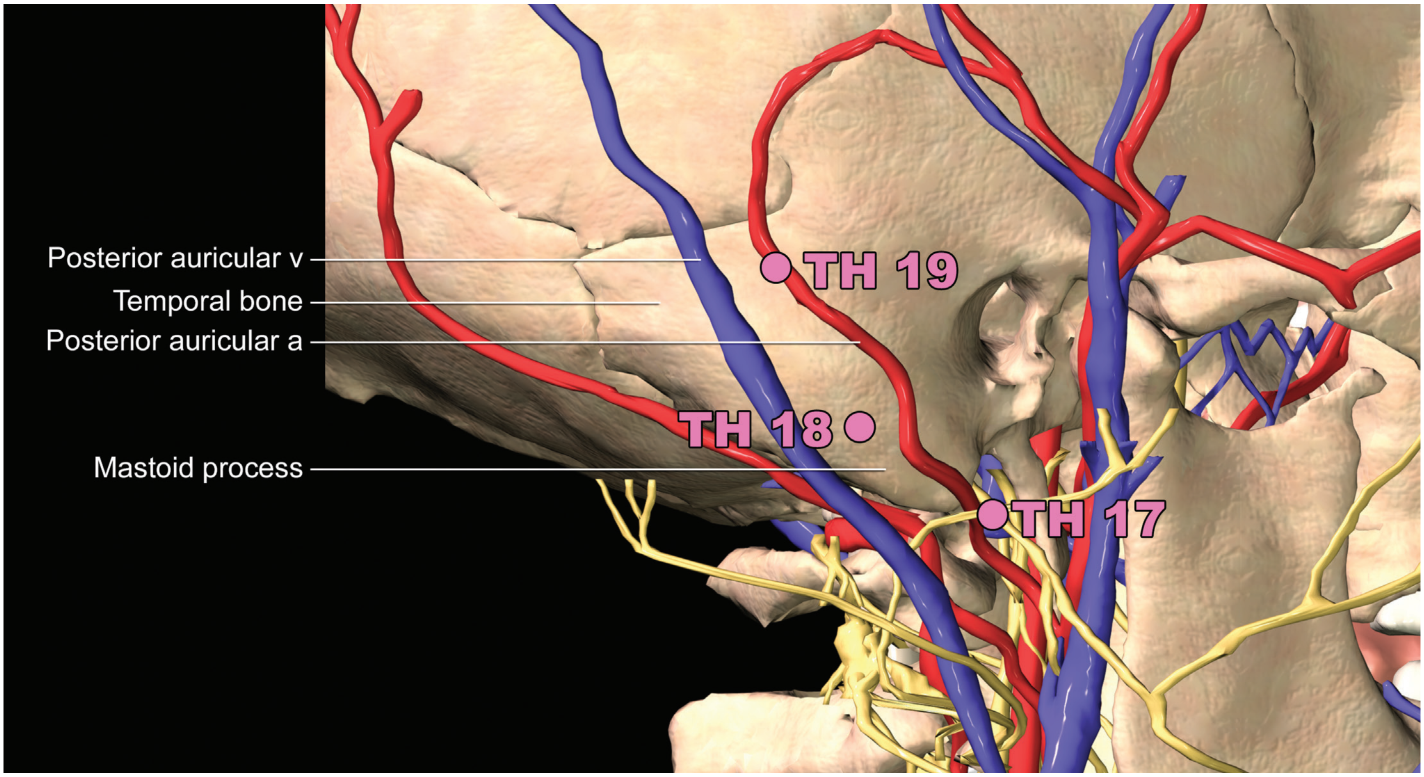

Figure 10-53. TH 19 continues the neurovascular relationship with the posterior auricular vessels (shown) and accompanying nerve (not shown) initiated by TH 17 and TH 18. Note, too, the proximity of TH 19 to the temporoparietal suture. Cranial sutures frequently exhibit tenderness to palpation. As such, TH 19 can assist in alleviating headache pain arising from cranial suture restriction and temporal bone dysfunction. When palpating TH 19, take care not to press too often or too firmly on only one temporal bone without supporting the contralateral temporal bone. Doing so may offset the patient's vestibular system and cause them to feel dizzy or unbalanced. Osteopathic physicians refer to the temporal bones as "troublemakers of the skull" with good reason; musculoskeletal maladies upset them easily.

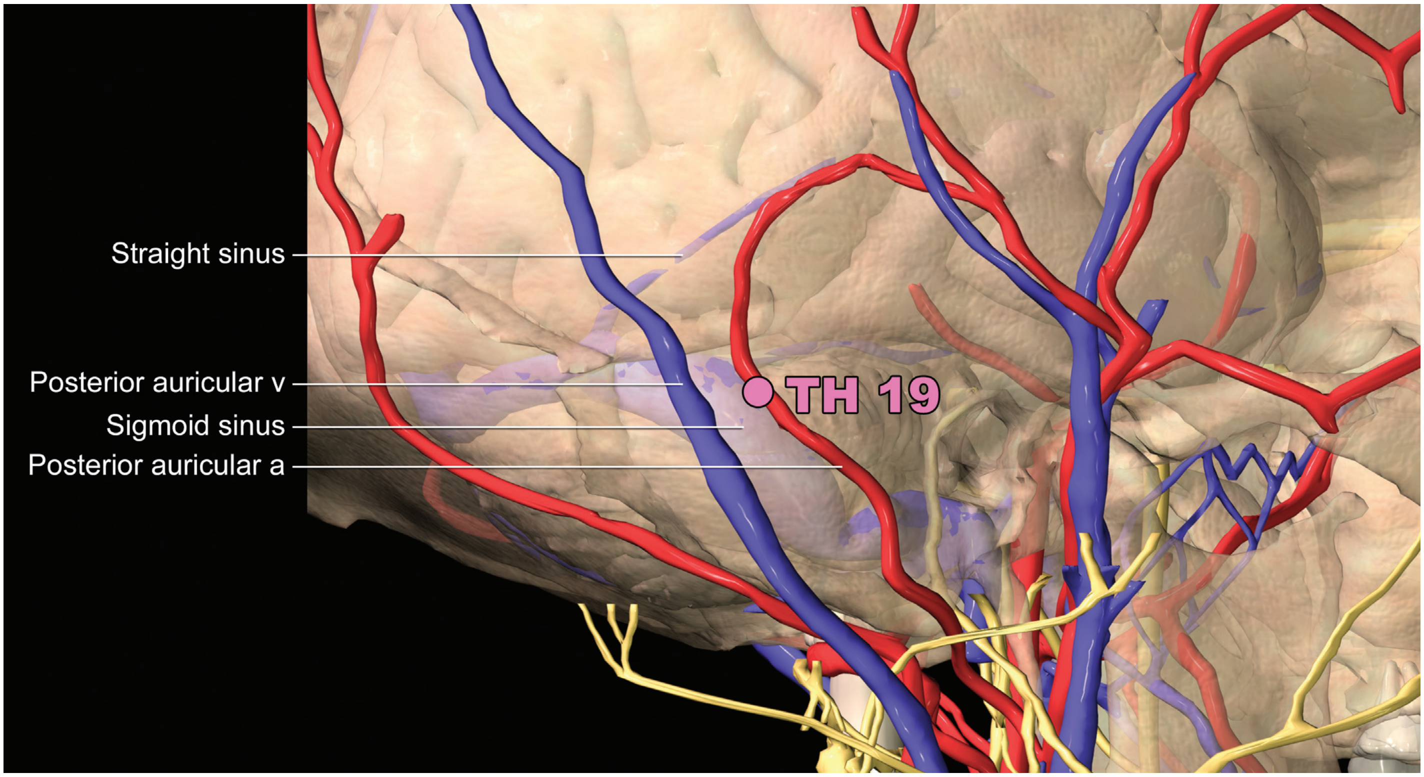

Figure 10-54. The term "Skull Rest" for TH 19 implies its clinical value for seizures. Neuromodulation for epilepsy involves invoking vagal stimulation, usually by means of nerves that crosstalk with the vagus nerve. Upper cervical spinal nerves make these connections, as through the great auricular nerve that supplies TH 19. Although the great auricular nerve does not appear in this image, the posterior auricular vessels do. Stimulating nervi vasorum associated with these structures may induce autonomic neuromodulation that benefits brain function. Furthermore, the fact that the posterior auricular vein receives an emissary vein from the sigmoid sinus anatomically argues that treating this region could influence venous drainage from the brain. To wit, an additional implication of the Chinese name, Lu Xi, refers to the treatment of a "clouded head" or "stuffiness" of the brain that connotes a disturbance in brain drainage or activity.

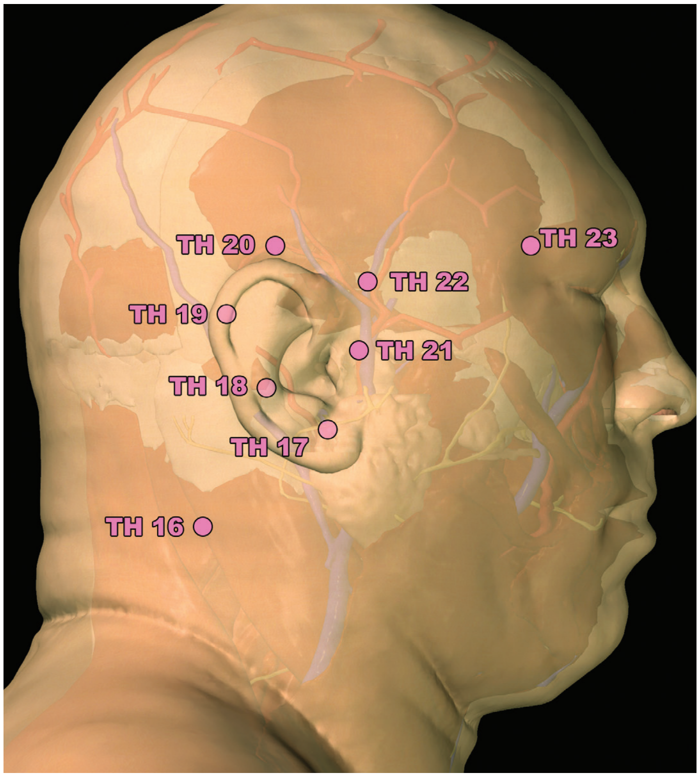

Figure 10-55. This image illustrates the context of TH 19 amid other TH point locations on the lateral head and neck.

muscles, parotid gland, facial nerve, auricle, scalp, and structures in the temporal bone.

- **Posterior auricular vein:** The posterior auricular vein not only drains the scalp posterior to the auricle, but it also often receives a mastoid emissary vein from the sigmoid sinus, which is one of the dural venous sinuses.

Clinical Relevance: The posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization offers one alternative to pharmacotherapy,[3] it seems unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear, inhabited by TH 18 and TH 19. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean

Figure 10-56. This cross section through TH 19 reveals its proximity to both the extracranial posterior auricular vein and the intracranial sigmoid venous sinus. The emissary venous connection between the two is implied, but not apparent here. Note, too, the relationship between TH 19 and the semicircular canal, located deep to the right ear and housed within the temporal bone. This anatomic proximity suggests that neuromodulation of the vestibular system by means of appropriately implemented laser therapy may benefit balance when delivered to TH points surrounding the auricle. Osteopathic cranial manipulative therapy also affects vestibular function. Apply treatment to both sides in order to provide even vestibular afferent input to the brainstem.

needling practices and to avoid deep scalp insertion as well as traversing infected sites. The spatial relationships between TH 19, the posterior auricular vein, the mastoid bone, and the sigmoid sinus show clearly in Figure 10-56.

Indications and Potential Point Combinations

- **Ear problems:** Pain, hearing loss, tinnitus: TH 19, TH 18, TH 17, TH 20, TH 21, local temporalis trigger points bilaterally.
- **Dizziness:** TH 19, TH 18, SCM trigger points, GV 20.
- **Temporal headache:** TH 19, TH 18, GV 20, BL 10, Taiyang, relevant temporalis trigger points.
- **Seizures:** TH 19, TH 18, ST 36, GV 20, Yintang (GV 24.5), BL 10, ST 36, LR 3.

TH 20

Jiao Sun "Angle Vertex", "Small Horn", "Angle of Collaterals"

On the side of the head, directly superior to the apex of the ear, within the hairline of the temporal region. The point can also be located by folding the posterior portion of the upper helix directly over the anterior portion, thereby indicating the point at the vertex. Or, have the patient open the mouth and palpate this region for a hollow that develops directly superior to the pinna.

Muscles

- **Superior auricular muscle:** The superior auricular muscle wiggles the ear. It is larger than the rostral (anterior) and caudal (posterior) auricular muscles, but also thin and fan-shaped. The fibers of the superior auricular muscle arise from the galea aponeurotica and converge to create a flat tendon that inserts onto the upper portion of the cranial aspect of the auricle.
- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: The superior auricular muscle, like its larger neighbor, the temporalis muscle, exhibits a fan pattern to its fibers. As such, the distribution of central trigger points in either muscle similarly arrange in a fan-like array rather than a straight line.

A common source of pain and dysfunction affecting the temporomandibular joint,[1] the temporalis muscle fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.

Nerves

- **Temporal branch of the facial nerve (CN VII):** The temporal branch of the facial nerve supplies the superior and anterior auricular muscles, the frontal belly of the occipitofrontalis (epicranius) muscle, and the superior part of the orbicularis oculi muscle.
- **Auriculotemporal nerve (CN V_3):** Supplies sensation to the skin anterior to the ear and in the posterior temporal region. Also provides innervation to the tragus and part of the helix of the auricle, the roof of the external auditory meatus and the upper tympanic membrane.

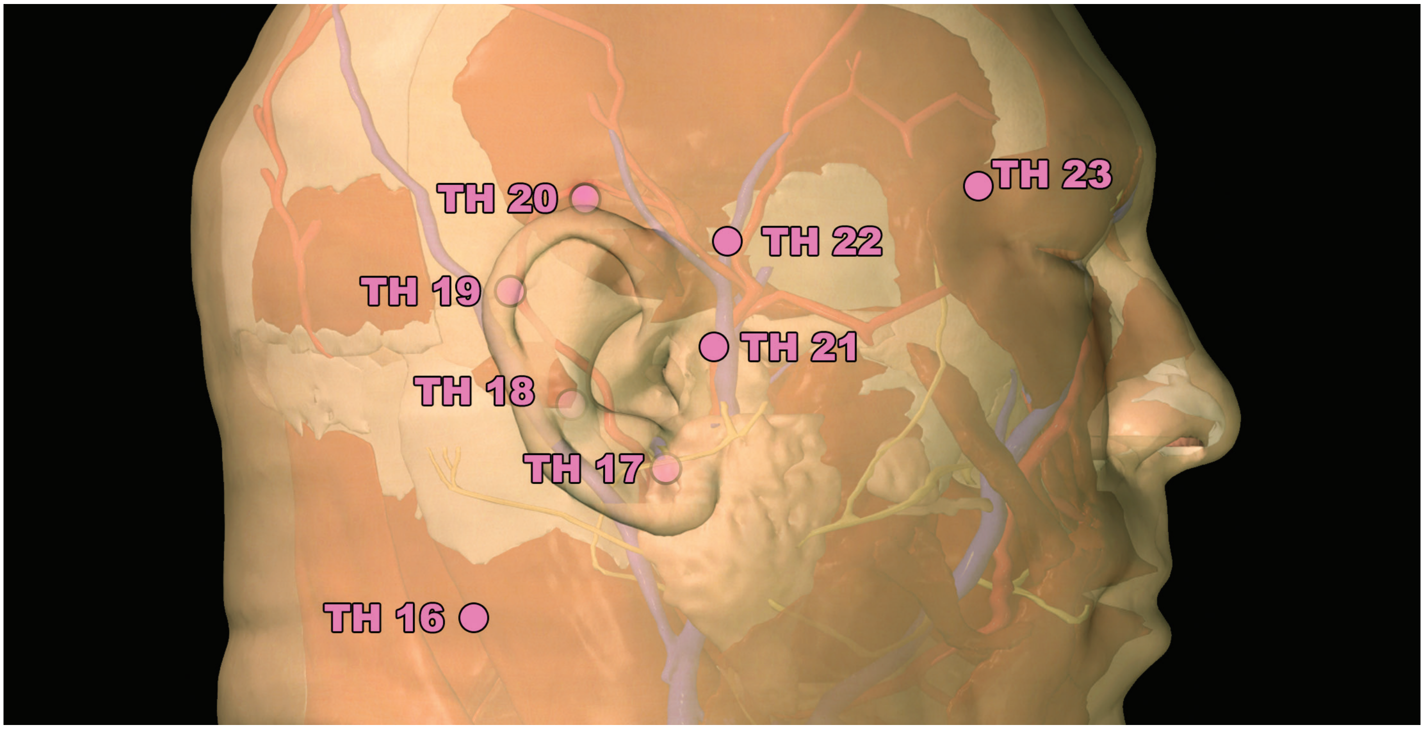

Figure 10-57. The TH line turns a corner at the vertex of the ear here at TH 20, substantiating the name "Angle Vertex". This location indicates where celestial dragon horns project from the head, justifying the alternate name, "Small Horn".

- **Anterior and posterior deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.
- **Lesser occipital nerve (C2):** This nerve provides innervation to the skin of the neck and the scalp lying posterior and superior to the auricle.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[2] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck should thus constitute a differential diagnosis for pain in the ear and TMJ.

Occipital neuralgia often affects the greater occipital nerve, but the lesser occipital may also produce the paroxysmal jabbing pain that nerve irritation induces.[3] Neuromodulation delivers effective treatment for occipital neuralgia.

Vessels

- **Posterior auricular artery:** This small branch of the external carotid artery ascends between the external acoustic meatus and the mastoid process. Its distribution includes the nearby muscles, parotid gland, facial nerve, auricle, scalp, and structures in the temporal bone.
- **Posterior auricular vein:** The posterior auricular vein not only drains the scalp posterior to the auricle, but it also often receives a mastoid emissary vein from the sigmoid sinus, which is one of the dural venous sinuses.
- **Superficial temporal artery:** Arises from the external carotid artery and ascends anterior to the ear, to the temporal region; ends in the scalp. Provides blood circulation to the facial muscles and the skin of the frontal and temporal regions.
- **Superficial temporal vein:** This vein arises from the widespread plexus of veins on the scalp's lateral aspect and along the zygomatic arch. The superficial temporal vein drains blood from the side of the scalp, the superficial portions of the temporal muscle, and the external ear.
- **Deep temporal arteries and veins:** Supply and drain the temporalis muscle.

Clinical Relevance: The posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization offers one alternative to pharmacotherapy,[4] it seems unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

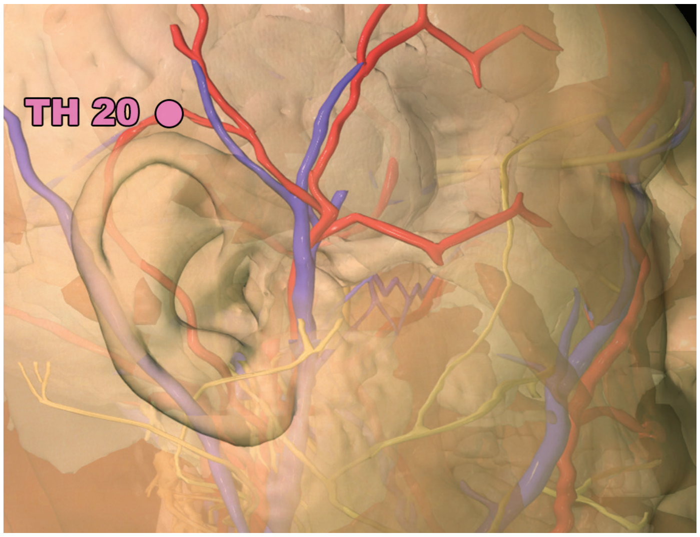

Figure 10-58. This image reveals the nearby anastomosis of the posterior auricular and a branch of the superficial temporal arteries rostral to TH 20. Hence the name for TH 20 of, "Angle of Collaterals" where the TH trajectory redirects toward this juncture of these vessels. The temporoparietal suture lies beneath the point, carrying a clinical significance for the treatment of headache and dizziness. In addition, the semitransparent skull near TH 20 shows the temporal lobe of the brain within reach of a suitably calibrated laser beam.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear, from TH 20 to TH 17. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

Indications and Potential Point Combinations

- **Headache:** Palpate the temporalis region as well as other muscles of the head, neck, shoulders, and back for myofascial trigger points. TH 20 may help patients with headache of temporalis origin.
- **Toothache:** Evaluate source of tooth pain, i.e., whether of odontologic or referred origin. Address trigger points in the temporalis muscle in the vicinity of TH 20, TH 21, and TH 22 that refer to the teeth. Trigger points in the temporalis muscle can cause the patient to become more sensitive (hyperesthetic) to percussion, chewing, or temperature changes in any or all of the ipsilateral upper teeth.

Figure 10-59. The temporalis muscle and temporal lobe of the brain relate to TH 20 as becomes apparent in this cross section. Functional magnetic resonance imaging (fMRI) studies of the brain have compared the effects of scalp acupuncture versus limb acupuncture on signal activation. Findings illustrate unique signal activations between the two groups, most likely resulting from the different afferent endings stimulated by each approach.[5] The scalp acupuncture group (needled at left-side only TH 20, GB 18, GB 9, and Sishencong) demonstrated more activity in the contralateral somatosensory association cortex, the postcentral gyrus, and the parietal lobe as compared to the limb acupuncture group, who received treatment at right-side only LI 1, LI 10, LR 3, and ST 36. Perhaps unsurprisingly, the latter points produced activation in the right occipital lobe, lingual gyrus, visual association cortex, right parahippocampal gyrus, limbic lobe, hippocampus, left anterior lobe, culmen, and cerebellum.

TH 21

Er Men "Ear Gate"

In a depression located anterior to the supratragic notch, at the "Ear Gate", posterior and slightly superior to the condylar process of the mandible when the mouth is open. Opening the mouth allows the mandible to slide forward to reveal the depression.

Gland

- **Parotid gland:** The largest of the three, paired salivary glands. The facial nerve courses through the parotid gland, as does the retromandibular vein, and the external carotid artery (ECA) and its nerve plexus. The gland contains parotid lymph nodes both within the gland and on its tough fascial capsule, the parotid sheath. These lymph nodes drain lymphatic fluid from the forehead, lateral eyelids, temporal region, lateral auricular surface, anterior wall of the external acoustic meatus, and the middle ear.

Clinical Relevance: A number of tumors, both benign and malignant, as well as infections can enlarge the parotid gland. Tumor growth within the gland can induce facial pain (mediated by the trigeminal nerve) and facial nerve dysfunction, leading to paresis or paralysis of the muscles of facial expression. Remain cognizant of the possible presence of salivary gland tissue at or near TH 21. Avoid needling tumorous or other abnormal tissue.

Muscles

- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: A common source of pain and dysfunction affecting the temporomandibular joint,[1] the temporalis muscle fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.

Nerves

- **Anterior and posterior deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.
- **Auriculotemporal nerve (CN V_3):** Supplies sensation to the skin anterior to the ear and in the posterior temporal region. Also provides innervation to the tragus and part of the helix of the auricle, the roof of the external auditory meatus and the upper tympanic membrane.
- **Deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle.
- **Temporal branch of the facial nerve (CN VII):** The temporal branch of the facial nerve supplies the superior and anterior auricular muscles, the frontal belly of the occipitofrontalis (epicranius) muscle, and the superior part of the orbicularis oculi muscle.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[2] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck should thus constitute a differential diagnosis for pain in the ear and TMJ.

Vessels

- **Superficial temporal artery:** Arises from the external carotid artery and ascends anterior to the ear, to the temporal region; ends in the scalp. Provides blood circulation to the facial muscles and the skin of the frontal and temporal regions.
- **Superficial temporal vein:** This vein arises from the widespread plexus of veins on the scalp's lateral aspect and along the zygomatic arch. The superficial temporal vein drains blood from

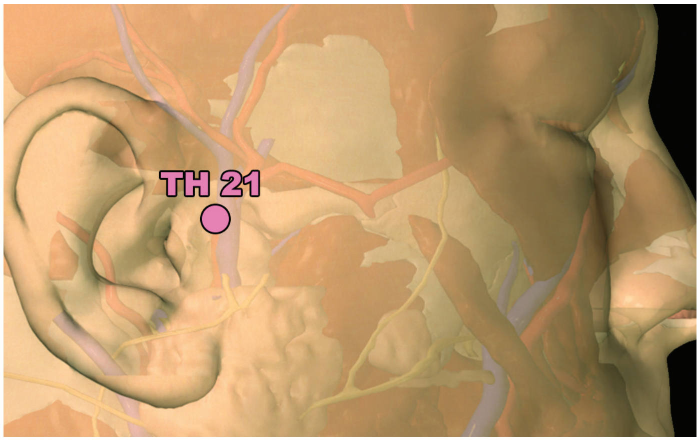

Figure 10-60. TH 21, as the "Ear Gate", is located in a depression anterior to the supratragic notch, at the gateway to the ear.

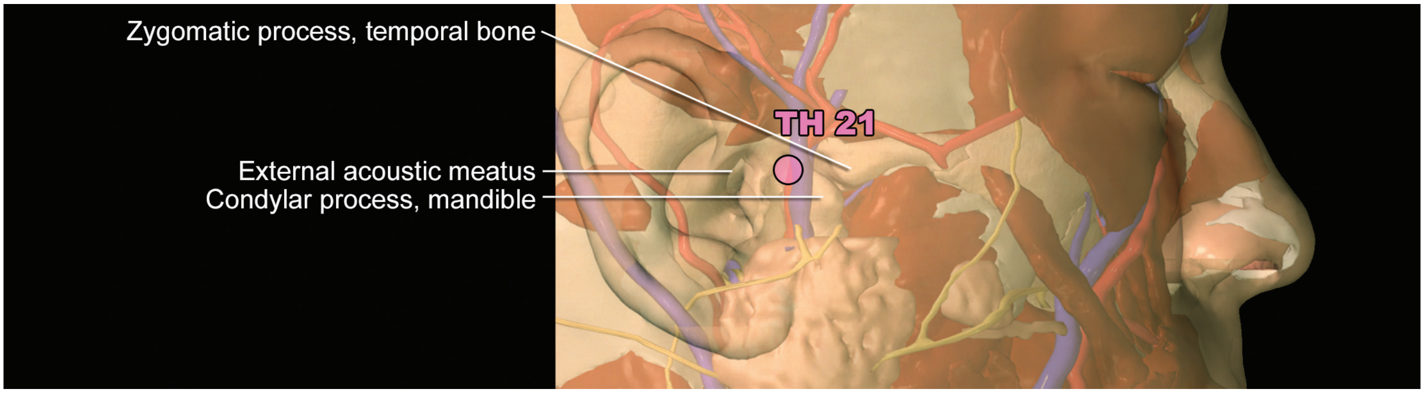

Figure 10-61. TH 21 sits directly over the TMJ, a complex source of local and referred pain.

the side of the scalp, the superficial portions of the temporal muscle, and the external ear.

- **Deep temporal arteries and veins:** Supply and drain the temporalis muscle.

Clinical Relevance: Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near TH 21, considering the limited responses to conventional methods often seen.[3]

Indications and Potential Point Combinations

- **Ear problems such as deafness, tinnitus, otitis media:** TH 21, TH 16, GB 20, GB 21, GV 20, GB 34. Examine myofascia of the head, neck, and torso for myofascial restrictions leading to tension on the temporal bone.
- **TMJ pain or dysfunction:** TH 21, SI 19, GB 2, TH 16, relevant and tender trigger points.
- **Headache:** Palpate the temporalis region as well as other muscles of the head, neck, shoulders, and back for myofascial trigger points. TH 21 may help patients with headache of temporalis origin.
- **Toothache:** Evaluate source of tooth pain, i.e., whether of odontologic or referred origin. Address trigger points in the temporalis muscle in the vicinity of TH 20, TH 21, and TH 22 that refer to the teeth.
- **Xerostomia:** TH 21, ST 7, ST 6, LI 4, ST 36.

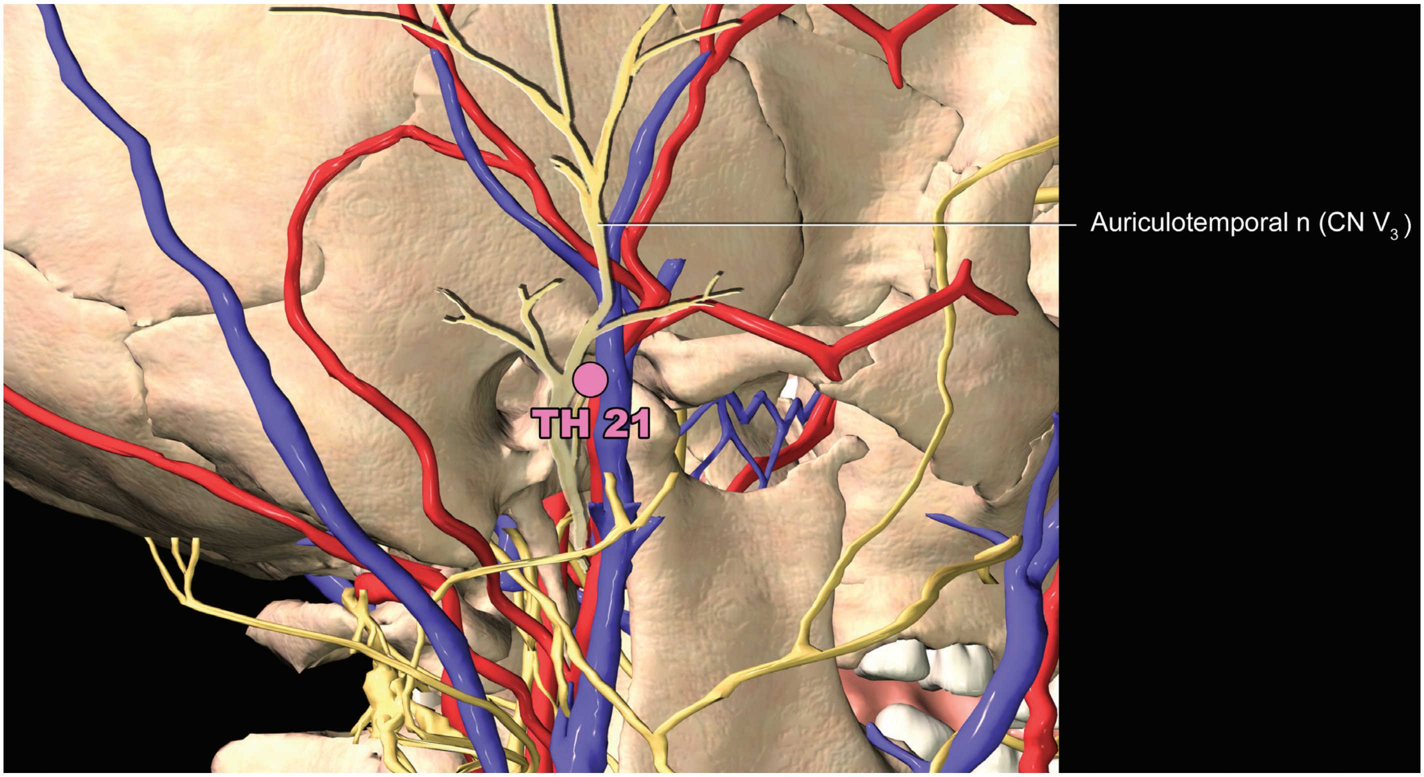

Figure 10-62. TH 21 relates closely to the superficial temporal vessels and their neural partner, the auriculotemporal nerve. This branch of the mandibular nerve (CN V_3) supplies the TMJ with articular fibers, fortifying its significance in treating TMJ pain. It communicates sensation from the auricle and temporal region. Finally, fibers from the auriculotemporal nerve join parasympathetic secretomotor fibers of glossopharyngeal origin (CN IX) to supply the parotid gland. These varied activities explain the clinical multifaceted applications associated with TH 21.

Figure 10-63. In addition to treating TMJ pain, needling at TH 21 can impact myofascial restriction in the temporalis muscle, as illustrated in this cross section. Transcranial laser therapy may affect the temporal lobe and the vestibular system, illustrated here by the semicircular canal, visible on the right side of the cross section. Otalgia and ear problems that cause it could be affected through laser and local stimulation of TH 21, at this “gateway to the ear”.

Evidence-Based Application

- Applying acupressure to trigger points at TH 21, GB 20, GV 20, BL 2, and GB 5 outperformed muscle relaxant medication for patients with **chronic headache** in a randomized controlled trial.[4]
- Acupuncture at TH 21 following cisplatin administration with “purple bamboo salt (PBS)-pharmaceutical acupuncture” significantly suppressed interleukin (IL)-6 production and caspase-3 activation induced by **cisplatin** in the cochlea. PBS also significantly inhibited cisplatin-induced apoptosis and IL-6 production in auditory cell lines, reduced cytochrome c release and caspase-3 activation. These cells also demonstrated inhibition of extracellular signal-related kinase and nuclear factor-kappa B activation.[5]
- Laser therapy delivered to TH 21, SI 19, GB 2, and auricular points liver, kidney, endocrine, and others, along with laser irradiation of the external auditory canal improved audition in patients with **moderate and severe sudden deafness.**[6]

TH 22

Er He Liao "Ear Harmony Crevice", "Holes Regularization", "Harmony Bone-Hole", "Grain Bone-Hole", "Harmony Hollow"

On the temporal region, anterior to the auricle and approximately 0.5 cun anterior (rostral) to the upper border of the root of the ear. In a small depression on the border of the natural hairline, level with the lateral canthus of the eye. As with all other acupuncture points, palpate the area for the best location for the patient; i.e., is the site tender or tense? Does it issue referred pain or reproduce the patient's pain? In this case the pain produced would likely include head pain, ear pain, or facial discomfiture.

Muscles

- **Superior auricular muscle:** The superior auricular muscle wiggles the ear.
- **Anterior auricular muscle:** The anterior auricular muscle wiggles the ear.
- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: The auricular muscles respond to emotional sites and sounds; their vestigial motor responses create enough activity for researchers to record but usually not sufficient in amplitude to move the pinna.[2] Usually, the posterior auricular muscle, also called the postauricular muscle or caudal auricular, displays the most consistent activation for both emotional images and sounds. As such, myofascial dysfunction and trigger points may arise due to chronic activation during highly charged emotional states, especially when turbulence affects the mind for long periods of time. Metaphorically, perhaps, the innervation of the auricular muscles by branches of the same nerve (i.e., CN VII), reflects inner struggle. That is, the anterior and superior auriculares receive motor supply from the temporal branch while the posterior auricular muscle receives the postauricular branch. In non-human animals, emotional reflexes remain distinct and expressive. Fear and anxiety pin the ears toward the back, while curiosity and affection bring them forward. These opposing "ear motions" thus reflect opposing "emotions". With regard to headaches and neuropathic pain generated by tension around the ears, a possible link could connect dysfunction in the posterior auricular muscle to traction and pulls on nervus intermedius territory, responsible in part for cluster headaches.

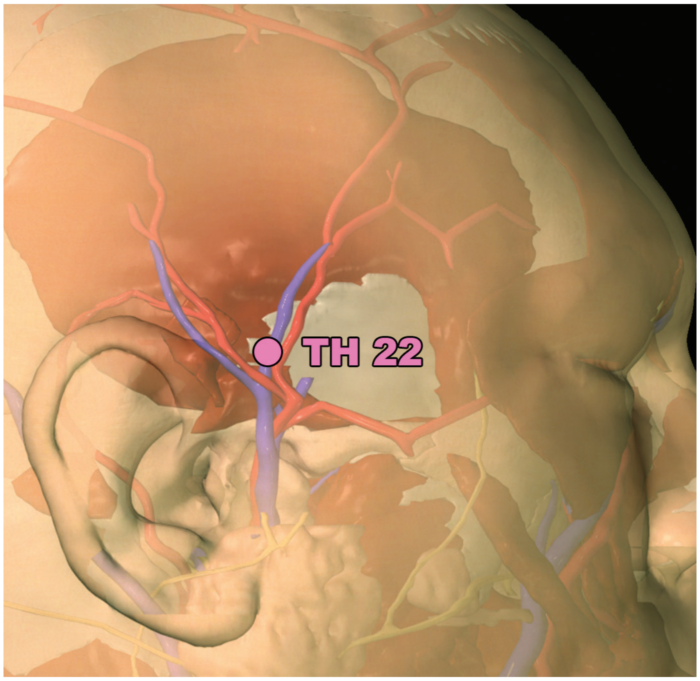

Figure 10-64. "Harmony Hollow" refers to the palpable "hollow" or depression in the temporalis muscle at TH 22, accentuated here to illustrate contour. The auriculotemporal nerve supplies the skin in this region as well as portions of the ear, including the roof of the external auditory meatus. The term "harmony" refers to the way in which the auriculotemporal nerve influences sensations of the ear canal and external auditory meatus, portals through which "harmonious sounds" travel toward the brain.

As a common source of pain and dysfunction affecting the temporomandibular joint,[1] the temporalis muscle fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.

Nerves

- **Auriculotemporal nerve (CN V_3):** Supplies sensation to the skin anterior to the ear and in the posterior temporal region. Also provides innervation to the tragus and part of the helix of the auricle, the roof of the external auditory meatus and the upper tympanic membrane. A sensory branch of an otherwise predominantly motor portion (i.e., the mandibular division) of the trigeminal nerve.
- **Temporal branch of the facial nerve (CN VII):** The temporal branch of the facial nerve supplies the superior and anterior auricular muscles, the frontal belly of the occipitofrontalis (epicranius) muscle, and the superior part of the orbicularis oculi muscle.

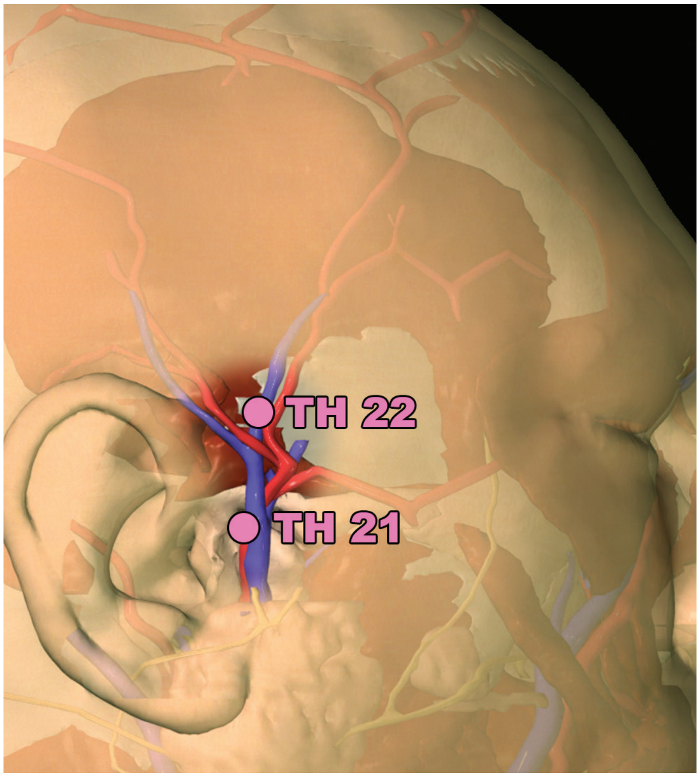

Figure 10-65. TH 21 and TH 22 line up along the superficial temporal artery and vein; both impact the temporalis muscle as well, shown here deep to the vessels. The auriculotemporal nerve (not shown) accompanies the superficial temporal vessels near the surface, while the deep temporal nerves (CN V_3, also not shown) follow close to the bone to supply the temporalis muscle.

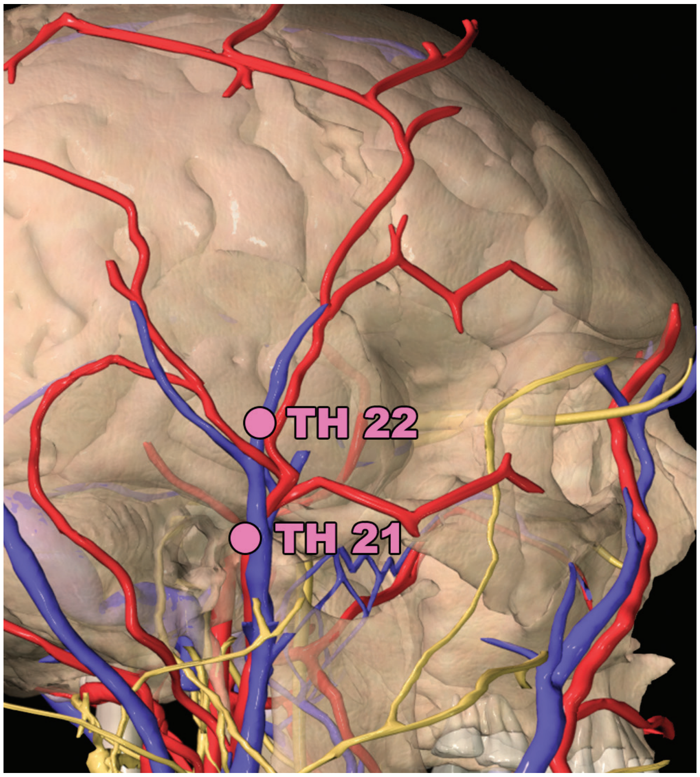

Figure 10-66. The wind-dispelling action of TH 22 according to Chinese medicine suggests that the point benefits patients with nervous system injury. This metaphorical "wind" referred either to facial nerve injury (both central and peripheral), vestibular system problems, and stroke affecting the temporal lobe, seen here deep to TH 22 and TH 21. GB points in the temporal region will continue this association. See, for example, Figure 11-12.

- **Anterior and posterior deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[3] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck should thus constitute a differential diagnosis for pain in the ear and TMJ.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[4] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Vessels

- **Superficial temporal artery:** Arises from the external carotid artery and ascends anterior to the ear, to the temporal region; ends in the scalp. Provides blood circulation to the facial muscles and the skin of the frontal and temporal regions.
- **Superficial temporal vein:** This vein arises from the widespread plexus of veins on the scalp's lateral aspect and along the zygomatic arch. The superficial temporal vein drains blood from the side of the scalp, the superficial portions of the temporal muscle, and the external ear.
- **Deep temporal arteries and veins:** Supply and drain the temporalis muscle.

Clinical Relevance: Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near TH 22, considering the limited responses to conventional methods often seen.[5]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and parotid arteries.[6]

Figure 10-67. The close association TH 22 has with the superficial temporal vessels and the temporalis muscle appears in this cross section. It reinforces the need to envision the three-dimensional anatomy beneath a point before vigorously stimulating it. This point-vessel relationship provides a clear-cut illustration of the vascular underpinnings of most acupuncture points and channels.

Pressure applied to TH 22 and ST 7 can lead to significant and reversible intracranial pressure (ICP) elevations in patients with already elevated ICP.[7] This finding suggests that if one chooses to treat acupuncture points on the head in patients with increased ICP, avoid adding pressure to the skull and instead select acupuncture or other forms of noninvasive neuromodulation.

Indications and Potential Point Combinations

- **TMJ pain or dysfunction:** TH 22, TH 21, SI 19, GB 2, TH 16, relevant and tender trigger points.
- **Headache:** Palpate the temporalis region as well as other muscles of the head, neck, shoulders, and back for myofascial trigger points. TH 22, TH 21, and TH 20 may help patients with headache of temporalis origin.
- **Toothache:** Evaluate source of tooth pain, i.e., whether of odontologic or referred origin. Address trigger points in the temporalis muscle in the vicinity of TH 20, TH 21, and TH 22 that refer to the teeth.

TH 23

Si Zhu Kong “Silken Bamboo Hollow”, “Bambooleaf Depression”

In the depression at the lateral end of the eyebrow, along the supraorbital margin.

Muscles

- **Orbicularis oculi muscle:** Closes the eyelids.
- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: Trigger points in the orbicularis oculi at and around TH 23 refer pain to the nose. Some pain may reach that portion of the cheek adjacent to the nose as far caudal as the upper lip.

The temporalis muscle, a common source of pain and dysfunction affecting the temporomandibular joint, fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.[1]

Nerves

- **Anterior and posterior deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.
- **Supraorbital nerve (CN V_1):** Innervates the mucous membranes of the frontal sinus and upper eyelid (i.e., the palpebral conjunctiva). Supplies the skin and subcutaneous tissue over the forehead and scalp, to the vertex. The frontal nerve consists of the conjoined supraorbital and supratrochlear nerves, which then is joined by a small sensory twig supplying the frontal sinus.[2] As the frontal nerve heads toward the superior orbital fissure along the roof of the orbit, it receives the lacrimal and nasociliary nerves.
- **Zygomatic nerve, which splits into the zygomaticofacial and**

Figure 10-71. Facial nerve injury of the temporal branch can rob the dorsal portion of the orbicularis muscle of its motor supply, at least temporarily. Treatment with acupuncture and related techniques may target the axon of this nerve branch that connects TH 17 to TH 23..

zygomaticotemporal nerves (CN V_2): Supplies sensation to the skin over the zygomatic arch and over the anterior temporal region. The zygomatic nerve transmits postsynaptic parasympathetic fibers that arise from the pterygopalatine ganglion to the lacrimal nerve. The zygomaticotemporal nerve provides the lacrimal gland with secretomotor function. Like the zygomaticotemporal nerve, the zygomaticofacial nerve emerges through a foramen that bears its name.

- **Lacrimal nerve (CN V_1):** The lacrimal nerve provides sensation to the lacrimal gland and a small area of skin and conjunctiva in the lateral part of the upper eyelid. Certain individuals lacks a lacrimal nerve; when this happens, the zygomaticotemporal nerve supplies sensation to the lacrimal gland.[7] A small branch of the zygomaticotemporal nerve may communicate with the auriculotemporal nerve from the mandibular division of the trigeminal nerve (CN V_3) and/or with the facial nerve.[7]
- **Temporal branch of the facial nerve (CN VII):** The temporal branch of the facial nerve supplies the superior and anterior auricular muscles, the frontal belly of the occipitofrontalis (epicranius) muscle, and the superior part of the orbicularis oculi muscle.
- **Zygomatic branch of the facial nerve (CN VII):** The zygomatic branch of the facial nerve supplies the orbicularis oculi muscle (mainly inferior portions) and other facial muscles inferior to the orbit.

Clinical Relevance: The pain that refers from an orbicularis oculi trigger point at TH 23 highlights communication between the facial nerve and the ophthalmic division of the trigeminal nerve. In this case, the referall of discomfort to the nose is explained by crosstalk with the nasociliary nerve and its terminal branches. These branches include the infratrochlear nerve that sends sensation from the medial eyelids and sides of the nose, and the external nasal nerve from the skin over the nostrils and nasal bridge.

TH 23 identifies a site of much crosstalk between nerves, involving branches from the ophthalmic and maxillary divisions of the trigeminal nerve and the zygomatic and temporal branches of the facial nerve. Review these intersections in Figure 10-72.

Specifically, the lacrimal nerve, a branch of the ophthalmic division (V1) conveys sensation from the lateral upper lid, conjunctiva, and lacrimal gland. Secretomotor (postganglionic, parasympathetic) fibers from the facial nerve (CN VII) travel briefly with the lacrimal nerve in its distal portion. The nerve then enters the orbit between the lateral rectus muscle and the orbital roof to join the nasociliary and frontal nerves at the superior orbital fissure. The lacrimal nerve communicates with the zygomaticotemporal nerve, which also travels in the company of postganglionic parasympathetic fibers from the facial nerve, destined for the lacrimal gland. The zygomaticotemporal nerve joins with the zygomaticofacial nerve to form the zygomatic nerve that courses along the orbit's floor to join the maxillary nerve after it enters the inferior orbital fissure. These interneural connections illustrate why TH 23 occupies a key location for stimulation in conditions involving impaired lacrimal secretion, such as dry and itching eyes.[3]

Communication between the facial and trigeminal nerve's zygomaticotemporal branches takes place between TH 23 and TH 22.[4] HIstochemical analyses of these connections suggest that the communicating branches contain myelinated fibers that could supply proprioceptive function, motor control, or both to periocular anatomy. These findings highlight the importance of sites on the face where such communications exist for recovery of facial nerve function following injury.

Figure 10-74. For TH 23, the name "Silken Bamboo Hollow" refers to the depression at the end of the eyebrow, metaphorically described as a "bamboo leaf". Note how as one courses laterad along the leaf, one hops off the steep cliff of the lateral orbit and lands in the lush temporalis muscle. Feel this on your own face and assess the tenderness to palpation here.

Entrapment or compression of the zygomaticotemporal branch of the trigeminal nerve appears to cause frontal migraine headaches.[5] Entrapment can occur due to pressure from the temporalis muscle because part of the nerve's journey takes it through the temporalis muscle or at least beneath its fascia. Treating trigger points with botulinum toxin type A injection may cause diplopia if it affects the lateral rectus muscle. Visual disturbances can last several months or more. Thus, safer means of deactivating trigger points in the zygomaticotemporal region would substitute acupuncture, laser therapy, and soft tissue manual treatment for pharmaceuticals and harsher methods.

Vessels

- **Zygomatico-orbital artery:** Arises from the superficial temporal artery and distributes to the orbicularis oculi muscle and parts of the orbit. The zygomatico-orbital artery anastomoses with branches of the ophthalmic artery.

Clinical Relevance: Scalp arteries with neuropathic vasa nervorum include the zygomatico-orbital, occipital, and posterior auricular vessels. Pressure on these vessels may lead to migraines. Patients with nociceptively charged arterial walls on their scalp exhibit tenderness to palpation both during headache and between migraines. Acupuncture and related techniques aid in reducing pressure on these vessels by neuromodulating nerve networks supplying vessels and allowing relaxation of compressive overlying soft tissues.

This new view of migraine etiology has been named the "trigeminovascular hypothesis of headache generation", suggesting a shift of perspective and treatments to target a extracranial as well as intracranial problems.[6]

Indications and Potential Point Combinations

- **Temporal headache:** TH 23, TH 22, tender GB and TH points as well as local temporalis trigger points, GB 21, BL 10.
- **Migraine (frontal):** TH 23, GB 14, BL 2, LI 4, LR 3, GV 20, and pertinent trigger points.
- **Dizziness, vertigo:** TH 23, TH 21, GB 20, BL 10, GV 20.
- **Eye problems: pain, inflammation, dryness, blepharospasm:** TH 23, GB 1, GB 20, BL 1, ST 36, LR 3, GV 20.

- **Facial paralysis:** Identify facial nerve branches involved. Begin with TH 17, follow the course of the affected facial nerve pathway(s) both along the axon and to the muscular destination.

TH 23 comes into play for problems closing the eye, when trauma or other pathology impairs the function of facial nerve branches supplying the orbicularis oculi muscle. BL 2 and GB 1 would be good adjunctive points.

- **Facial pain:** A trigger point at TH 23 refers pain that extends in a medial direction along the eyebrow, down the nose and to the surrounding cheek and upper lip. TH 23, BL 2, LI 20 follow this pain pattern.

Evidence-Based Applications

- Treatment with acupuncture at TH 23, GB 14, BL 2, Taiyang, ST 1, GB 20, LI 4, LI 11, and GV 23 improved **dry eye** patients' ocular surface disease index (OSDI), lessened pain, and increased tear film break up time significantly after eight weeks of treatment.[7]
- Acupuncture at TH 23, BL 2, and Taiyang stimulated **lacrimal gland secretion and improved protein levels** in tear of rabbits receiving acupuncture.[8]

Channel 11:: The Gallbladder (GB)

The GB line embarks on its long voyage just lateral to the lateral canthus of the eye. It zigzags from head to foot over the lateral aspect of the body until it reaches the foot and the 4th toe. Together with the TH line, the GB channel travels along that aspect of the body that acts to turn a cartwheel.

The GB channel trajectory overlies areas primarily involved with structural problems and associated pain.

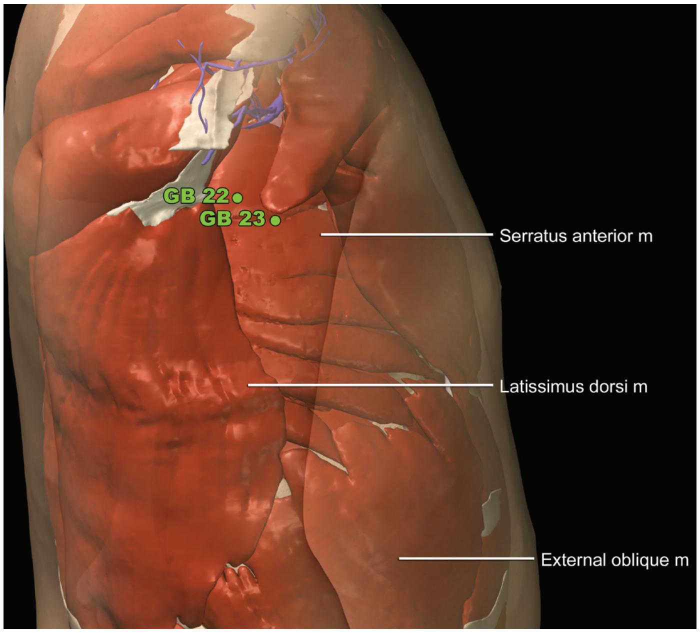
Most human adults and many children harbor tension in the trapezius trigger point at GB 21. Pain issued from GB 21 typically follows the GB trajectory over the head. It may also produce pain at the angle of the mandible at SI 17. This lateral perspective of the extracranial and neck/shoulder musculature outlines the GB pathway traversed by referred pain from GB 21.



GB 22
GB 23
Serratus anterior m
Latissimus dorsi m
External oblique m

This image of the upper lateral thorax shows GB 22, GB 23 and the latissimus dorsi and serratus anterior muscles respectively. Trigger points in the latissimus dorsi muscle produce pain in the mid thorax at the caudal end of the scapula. This pain may extend down the SI and TH lines of the thoracic limb. Trigger points in the serratus anterior produce painful, paresthetic, and possibly pruritic patterns that create diagnostic enigmas. "Notalgia paresthetica" denotes long thoracic nerve irritation and myofascial dysfunction of the serratus anterior muscle. Referred pain pattern from trigger points in the serratus anterior overlaps considerably with that of notalgia paresthetica, suggesting a common pathophysiology. Pain may extend along the HT and PC lines of the thoracic limb.

GB points (GB 24 to GB 28) encircle the abdomen and ride over the rim of the pelvis. Myofascial trigger points in the oblique and transverse abdominal muscles cause abdominal wall pain plus or minus visceral dysfunction. Trigger point pathology in the external oblique muscle at GB 24 may induce heartburn-like pain. GB 25 identifies the location of the "belch button", associated with eructation and projectile vomiting. Trigger points at GB 26, GB 27, and GB 28 provoke groin or testicular pain and diarrhea.

The fascia lata on the pelvic limb forms a "veritable stocking" or "ectoskeleton" for the muscles it embraces. The iliotibial band (ITB) constitutes a thickening of this fascia on the lateral thigh. The ITB functions as a tendon for the tensor fasciae latae and gluteus maximus muscles. It also acts as a brace for the knee by providing lateral stability. Palpate the ITB for trigger point pathology and deactivate accordingly. The convergence of the GB line and the ITB denotes the value of GB points (i.e., GB 29 through GB 33) for ITB syndrome.

The GB line from knee to foot follows the peroneus (now called fibularis) muscles and both superficial and deep branches of the peroneal (fibular) nerve. In keeping with the motif set by more proximal pelvic limb GB points, those on the distal limb, ankle, and foot also impact stabilizing structures.

GB 1

Tong Zi Liao "Pupil Crevice", "Pupil Bone Hole"

In a small depression on the lateral rim of the orbit, 0.5 cun lateral to the outer canthus of the eye.

Muscles

- **Orbicularis oculi muscle:** Closes the eye and wrinkles the overlying skin.
- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: Mechanical or emotional strain in the orbicularis oculi muscle may lead to "twitching" or fasciculation around the eye. Acupressure applied to GB 1 often stops the twitch. The temporalis muscle, a common source of pain and dysfunction affecting the temporomandibular joint, fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.[1]

Nerves

- **Anterior and posterior deep temporal nerves (CN V$_3$):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.
- **Lacrimal nerve (CN V$_1$):** Supplies the skin over the lateral upper eyelid, the conjunctiva deep to this region, and the lacrimal gland.
- **Zygomatic nerve, which splits into the zygomaticofacial and zygomaticotemporal nerves (CN V$_2$):** Supplies sensation to the skin over the zygomatic arch and over the anterior temporal region. The zygomatic nerve transmits postsynaptic parasympathetic fibers that arise from the pterygopalatine ganglion to the lacrimal nerve. The zygomaticotemporal nerve provides the lacrimal gland with secretomotor function. Like the zygomaticotemporal nerve, the zygomaticofacial nerve emerges through a foramen that bears its name.
- **Zygomatico-facial nerve (CN V$_2$):** Supplies the skin over the zygomatic arch and the anterior temporal zone. Carries postsynaptic parasympathetic fibers from the pterygopalatine ganglion to the lacrimal nerve.

Figure 11-1. GB 1, "Pupil Crevice", denotes the opening through which the pupil peers. The orbicularis oculi muscle forms the sphincter that creates this crevice. The muscle receives its motor supply from the facial nerve, temporal branch (shown here) and the zygomatic branch (not shown). GB 1 coincides with the motor point of the orbicularis oculi muscle. Chronic activation of this ocular sphincter cultivates skin folds known as "crow's feet". Emotional or somatic overstimulation can produce an "eye tic".

Figure 11-2. Neural input from the trigeminal and facial nerves converges at GB 1. These intersecting nerves provide effective opportunities by which to address ophthalmic disorders such as impaired lacrimation and ocular pain

- **Facial nerve (CN VII), temporal and zygomatic branches:** Innervate the superior and inferior parts of the orbicularis oculi muscle, respectively. The temporal branch also supplies the auricularis superior and auricularis anterior muscles, as well as the frontal belly of the occipitofrontalis muscle. The zygomatic branch supplies muscles inferior to the orbit, in addition to the orbicularis oculi muscle. GB 1 is the motor point for the orbicularis oculi muscle.[2]

Clinical Relevance: The lacrimal, supraorbital, and zygomaticotemporal, and zygomaticofacial nerves supply sensation to the skin of the lateral canthus at and around GB 1. The latter two (zygomaticotemporal and zygomaticofacial) communicate with the auriculotemporal nerve (from V3) through a small branch, neuroanatomically linking GB 1 to GB 2. Stimulation of trigeminal nerve branches near the orbit causes reflex activation of autonomic ganglia, leading to reflex vasodilation of vessels

leading to the eye. Trigeminal stimulation also invokes release of the vasoactive neuropeptides, calcitonin gene-related peptide (cGRP) and substance P. This reflex arc induces the release of vasoactive intestinal polypeptide (VIP) and nitric oxide (NO).[8,9] Crosstalk between periocular trigeminal nerve branches (most notably the lacrimal and zygomatic nerves) carries parasympathetic, postganglionic secretomotor fibers from the facial nerve to the lacrimal gland. These aspects of the neuroanatomy supplying GB 1 speaks to its frequent inclusion in acupuncture protocols for dry eye conditions.[10]

Vessels

- **Zygomatico-orbital and zygomatico-temporal arteries:** Provide blood flow to this small region of the face.

Clinical Relevance: Scalp arteries that develop neuropathic vasa nervorum include the zygomatico-orbital, occipital, and posterior auricular vessels. Pressure on these vessels may lead to migraines. Patients with nociceptively charged arterial walls on their scalp exhibit tenderness to palpation both during and between migraines. Acupuncture and related techniques aid in reducing pressure on these vessels by neuromodulating nerve networks that supply cranial vessels and by allowing relaxation of overlying soft tissues.

This new view of migraine etiology has been named the "trigeminovascular hypothesis of headache generation", suggesting an expanded perspective that targets extracranial sources in conjunction with intracranial abnormalities.[11]

Indications and Potential Point Combinations

- **Conjunctivitis, dry eye (keratoconjunctivitis sicca):** GB 1, TH 23, BL 2, ST 2, GV 20, ST 36, LR 3.
- **Headache radiating to the eye:** GB 1, BL 10, temporalis trigger points, GV 14, GV 20.
- **Facial tic, eye twitch:** GB 1, follow facial nerve from TH 17 along zygomatic branch and temporal branch (also consider ST 6, SI 18)
- **"Crow's feet" wrinkles:** GB 1, temporalis trigger points.
- **Optic nerve atrophy:** GB 1, GB 20, BL 1, LI 4, KI 7, SP 6, and LR 3.

Evidence-Based Applications

- Acupuncture at ST 2, ST 8, ST 36, GB 1, GB 14, BL 2, and LI 4 provided subjective beneficial effects in patients with **keratoconjunctivitis sicca (KCS, or dry eye).**[3]
- Both laser and needle acupuncture at GB 1, BL 2, ST 5, Yintang, LI 4, SI 3, LR 3, KI 6, and TH 5 worked equally well in improving objective measurements of **KCS.**[4]
- Electroacupuncture at GB 1/LR 14 and LR 3/ LR 8, along with dry needling at LR 14, GB 41, and ST 1 led to statistically significant improvement in **dry eye symptoms** in 88% of patients.[5]
- GB 1 and ST 4 successfully resolved **idiopathic Horner's syndrome** in a dog after two treatments.[6]
- By employing "commonly used points": BL 1, GB 1, GB 20, LI 4, KI7, SP6, and LR3, along with "reserve points" (BL 2, ST 2, TH 5,

GB 37, ST 36, KI3, KI 6, LR 8, PC 6, BL 13, BL 18, BL 21, GV4, BL 10, SI 6, BL 58, and BL 23 produced improvement in patients suffering from **optic nerve atrophy or optic neuritis.**[7]

- Acupuncture at GB 1, GB 14, and BL 1 lowered **intraocular pressure** in healthy subjects but was not significantly different from sham points, showing the need for a neuroanatomically based selection of sham points that produce no neurophysiologic overlap.[12]

GB 2

Ting Hui "Auditory Convergence"

Anterior to the intertragic notch of the auricle and posterior to the condylar process of the mandible. Directly below SI 19. Locate with the patient's mouth open.

Gland

- **Parotid gland:** The largest of the three, paired salivary glands. The facial nerve courses through the parotid gland, as does the retromandibular vein, and the external carotid artery (ECA) and its nerve plexus. The gland contains parotid lymph nodes both within the gland and on its tough fascial capsule, the parotid sheath. These lymph nodes drain lymphatic fluid from the forehead, lateral eyelids, temporal region, lateral auricular surface, anterior wall of the external acoustic meatus, and the middle ear.

Clinical Relevance: A number of tumors, both benign and malignant, along with infections can amplify the size of the parotid gland. Tumor growth within the gland can induce facial pain (mediated by the trigeminal nerve) and facial nerve dysfunction, leading to paresis or paralysis of the muscles of facial expression. Surgical procedures affecting the parotid gland may injure the facial nerve and/or the retromandibular vein.[6]

Remain cognizant of the possible presence of salivary gland tissue at or near GB 2. Avoid needling tumorous or otherwise abnormal tissue.

Nerves

- **Glossopharyngeal nerve (CN IX):** Supplies secretory fibers to the parotid gland, carried by the auriculotemporal nerve to the parotid, from the otic ganglion.
- **Sympathetic nerve fibers (T1-T5):** These fibers reach the parotid gland after leaving the cervical sympathetic ganglia and coursing along the external carotid nerve plexus on the external carotid artery.
- **Auriculotemporal nerve (CN V_3):** Provides sensory innervation to the parotid gland. Provides sensation to the skin anterior to the ear and posterior temporal region, the tragus and part of the helix of the auricle, the roof of the exterior auditory meatus, and the upper tympanic membrane.
- **Facial nerve trunk (CN VII):** The facial nerve trunk forms the parotid plexus, engulfed by the parotid gland. The parotid plexus forms the five terminal branches of the facial nerve – temporal, zygomatic, buccal, mandibular, and cervical.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects the head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. Neuromodulation of nerves supplying the TMJ, local musculature, and nearby vessels provides analgesia and alleviates myofascial dysfunction for this craniomandibular disorder.

In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[7] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck thus constitutes a differential diagnosis for pain in the ear and TMJ.

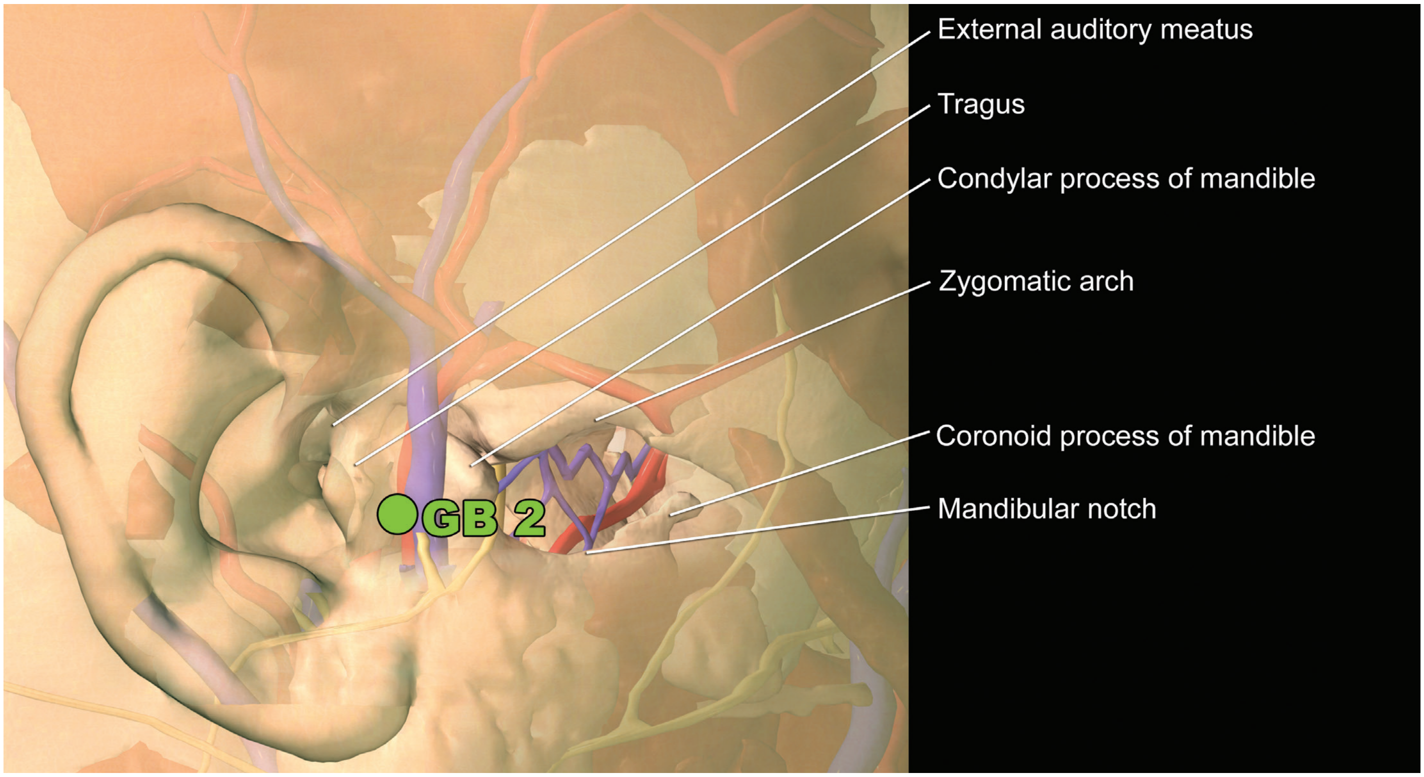

Figure 11-5. GB 2 earns the name "Auditory Convergence" by dint of its close connection with the ear and structures that supply it.

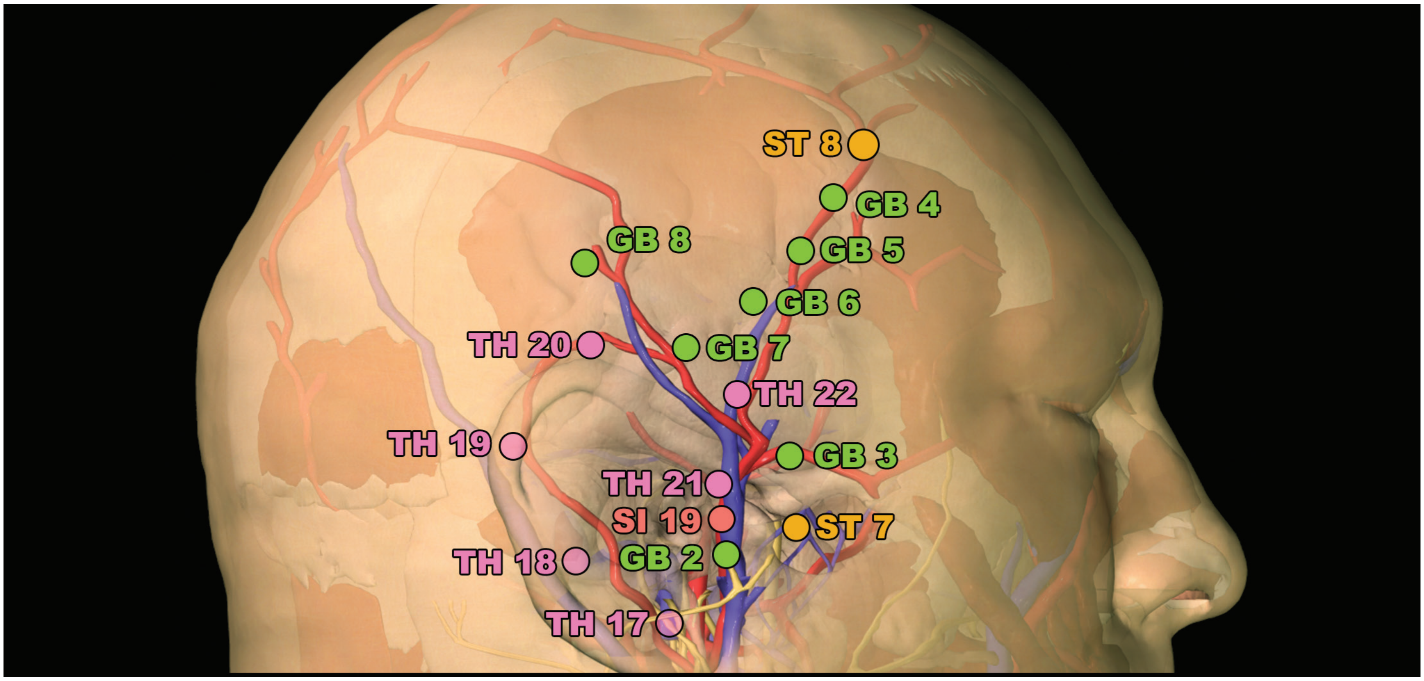

Figure 11-6. Acupuncture points map out a busy neurovascular traffic pattern that surrounds the ear and courses from TMJ to the temple. A neuropathic auriculotemporal nerve, which would follow the vessels shown here mapped out by the GB points, would precipitate or worsen TMJ pain and balance disturbances.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[8] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a “perfect storm” for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersection with the superficial temporal vessels can occur at GB 2 and elsewhere along the nerve pathway. This may induce migraine and acts as an anatomical trigger zone.[9]

Dysfunction in the auriculotemporal nerve can disturb gait and balance, as the visual, vestibular, skeletal, and stomatognathic (dental) systems all coordinate to allow an individual to maintain equilibrium, balance, proper posture and normal gait.[1] The neuroanatomic connection between somatic structures and vestibular function provides a structure-function explanation that supports the treatment of this region either with acupuncture or manipulative therapy for balance disorders. The auriculotemporal nerve communicates with the buccal, zygomatic, temporal, and upper divisions of the facial nerve suggesting that GB 2 may assist in facial nerve recovery after injury.[2] The auriculotemporal nerve accompanies branches from the masseteric nerve to supply sensation to the TMJ, the articular element of this oft-referred to source of face and head pain.

Vessels

- **Zygomatico-orbital artery:** Provides blood flow to this small area of the face.
- **Transverse facial artery:** A branch of the superficial temporal artery that originates within the parotid gland. It supplies the parotid gland and duct, the masseter muscles, and the skin in that vicinity. It anastomoses with the facial artery.
- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.
- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.
- **Retromandibular vein:** The retromandibular vein forms from the union of the maxillary and superficial temporal veins, rostral to the ear. It later joins with the posterior auricular vein to create the external jugular vein. The retromandibular vein drains the parotid gland and masseter muscle.

Clinical Relevance: Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 2, considering the limited responses to conventional methods often seen.[10]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and parotid arteries.[11]

Figure 11-7. This cross section exhibits the structures within reach of a needle entering GB 2. These include the retromandibular vein and the parotid gland, anatomy that deep needling could injure. Remember, too, that preauricular lymph nodes reside in this region, though not shown here.[13]

Direct the acupuncture needle away from vessels and toward, but not into, the joint. Refer to Figure 11-7 for the relative location of the right retromandibular vein to GB 2.

Indications and Potential Point Combinations

- **Ear problems:** otitis media, deafness: GB 2, TH 18, TH 20.
- **Tinnitus:** GB2, SI 19, trigger points in muscles connecting to the temporal bone, tender TH points encircling the ear.
- **Facial numbness:** GB 2 plus acupuncture points in the vicinity of the numbness.
- **Facial paralysis:** Facial nerve branches afflicted, TH 17 (facial nerve trunk at its exit from the skull), and GB 2 for the crosstalk between the auriculotemporal nerve and facial nerve motor branches.
- **Toothache referred from auriculotemporal neuralgia:**[3] GB 2, temporalis trigger points.
- **TMJ disorders:** Ascertain, to the degree possible, the source of orofacial and specifically TMJ pain. Articular disorders of the TMJ may include derangement of the cranial bones or mandible, neoplasia of the TMJ or associated anatomic elements, disk disturbances, inflammation, arthritis, TMJ dislocation or fracture of the condylar process.[4] Given that the auriculotemporal nerve supplies the TMJ, GB 2 and the other points that follow this nerve come into play as potentially suitable avenues for stimulation, as shown in Figure 11-6.
- **Balance disorders, disturbances in gait, posture, and equilibrium:** Consider auriculotemporal nerve dysfunction.[5] GB 2, GB 20, BL 10, Yintang, GV 20, GV 16 (needled carefully).

Evidence-Based Application

- Laser therapy delivered to TH 21, SI 19, GB 2, and auricular points liver, kidney, endocrine, and others, along with laser irradiation of the external auditory canal improved audition in patients with moderate and severe **sudden deafness.**[12]

GB 3

Shang Guan "Above the Joint", "Upper Gate"

Rostral to the ear, on the dorsal border of the zygomatic arch, in a depression directly above ST 7. First locate ST 7 in the depression rostral to the condylar process of the mandible and ventral to the zygomatic arch. Run a palpating finger up and over the zygomatic arch to the tender site or hollow dorsal to ST 7.

Muscles

- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: The temporalis muscle, a common source of pain and dysfunction affecting the temporomandibular joint, fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.[1]

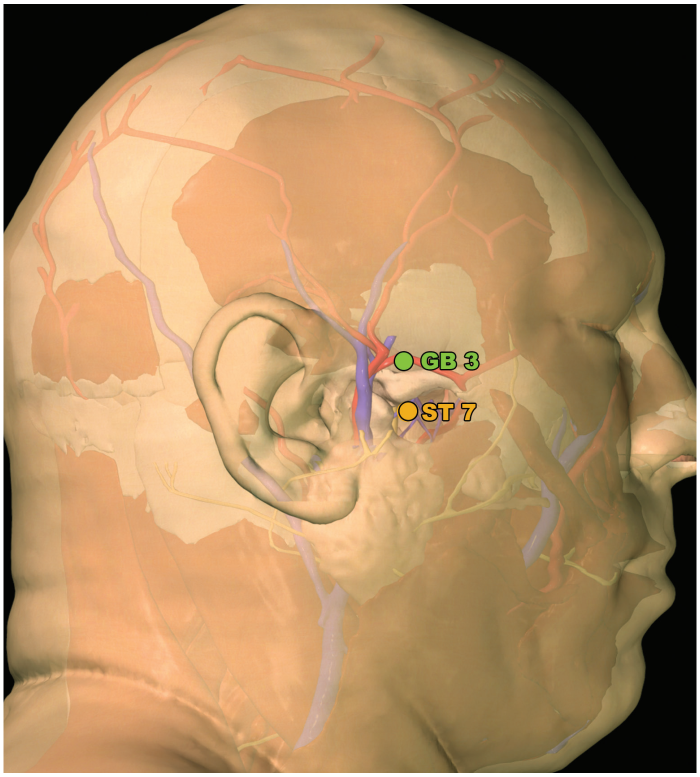

Figure 11-8. GB 3, the "Upper Gate", sits "Above the Joint", highlighting its alternate name, while ST 7, the "Lower Hinge", lies "Below the Joint". The "joint" is the temporomandibular joint (TMJ).

Nerves

- **Anterior and posterior deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.
- **Auriculotemporal nerve (CN V_3):** Provides sensory innervation to the parotid gland. Provides sensation to the skin anterior to the ear and posterior temporal region, the tragus and part of the helix of the auricle, the roof of the exterior auditory meatus, and the upper tympanic membrane.
- **Facial nerve (CN VII), temporal branch:** Supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior portion of the orbicularis oculi muscle.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects the head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. Neuromodulation of nerves supplying the TMJ, local musculature, and nearby vessels provides analgesia and alleviates myofascial dysfunction for this craniomandibular disorder.

In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[5] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck thus constitutes a differential diagnosis for pain in the ear and TMJ.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[6] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can

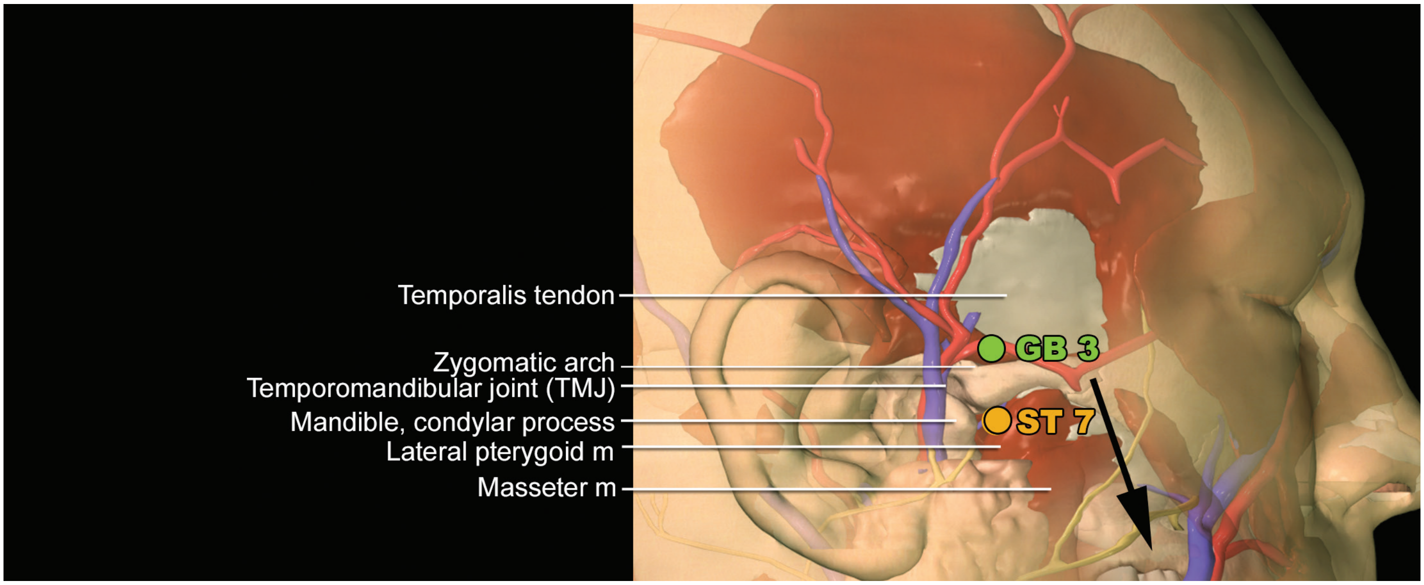

Figure 11-9. Trigger points in the vicinity of GB 3 refer pain toward the vertex or toward the teeth, mainly the maxillary molars, as indicated by the black arrow.

occur at GB 3 and elsewhere along the neurovascular course. Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[7]

Vessels

- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.
- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.
- **Zygomatico-orbital artery:** Provides blood flow to this small area of the face.
- **Transverse facial artery:** A branch of the superficial temporal artery that originates within the parotid gland. It supplies the parotid gland and duct, the masseter muscles, and the skin in that vicinity. It anastomoses with the facial artery.

Clinical Relevance: Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 3, considering the limited responses to conventional methods often seen.[8]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supra-orbital, deep temporal, buccal and parotid arteries.[9]

Direct the acupuncture needle away from vessels and toward, but not into, the joint. Refer to Figure 11-11 for the relative location of the right retromandibular vein to GB 3.

Indications and Potential Point Combinations

- **Ear problems:** otitis media, deafness: GB 3, GB 2, TH 18, TH 20.
- **Tinnitus:** GB 3, GB 12, SI 19, trigger points in muscles connecting to the temporal bone, tender TH points encircling the ear.
- **Facial numbness:** GB 3, GB 2, plus acupuncture points that pertain specifically to the nerve responsible for facial sensation (usually a trigeminal nerve branch).
- **Facial paralysis:** Facial nerve branches afflicted, TH 17 (facial nerve trunk at its exit from the skull), GB 3, and GB 2 for the crosstalk between the auriculotemporal nerve and facial nerve motor branches.
- **Toothache referred from auriculotemporal neuralgia:**[2] GB 3, GB 2, temporalis trigger points.
- **TMJ dysfunction:** Ascertain, to the degree possible, the source of orofacial and specifically TMJ pain. Articular disorders of the TMJ may include derangement of the cranial bones or mandible, neoplasia of the TMJ or associated anatomic elements, disk disturbances, inflammation, arthritis, TMJ dislocation or fracture of the condylar process.[3] Given that the auriculotemporal nerve supplies the TMJ, points that lie along the trajectory of this nerve may help confer analgesia. Palpate carefully to determine which branches warrant attention.
- **Balance disorders, disturbances in gait, posture, and equilibrium:** Consider auriculotemporal nerve dysfunction.[4] GB 3, GB 2, GB 20, BL 10, Yintang, GV 20, GV 16 (needled carefully).

GB 4

Han Yan "Forehead Fullness", "Jaw Stretching"

On the temporal region, caudal to the natural hairline, 1/4 the distance from ST 8 to GB 7. The temporalis muscle bulges just below this point when the teeth clench.

Muscles

- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: The temporalis muscle, a common source of pain and dysfunction affecting the temporomandibular joint, fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.[1]

Nerves

- **Anterior and posterior deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.
- **Auriculotemporal nerve (CN V_3):** Provides sensory innervation to the parotid gland. Provides sensation to the skin anterior to the ear and posterior temporal region, the tragus and part of the helix of the auricle, the roof of the exterior auditory meatus, and the upper tympanic membrane.
- **Facial nerve (CN VII), temporal branch:** Supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior portion of the orbicularis oculi muscle.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects the head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. Neuromodulation of nerves supplying the TMJ, local musculature, and nearby vessels provides analgesia and alleviates myofascial dysfunction for this craniomandibular disorder.

In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[2] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck thus constitutes a differential diagnosis for pain in the ear and TMJ.

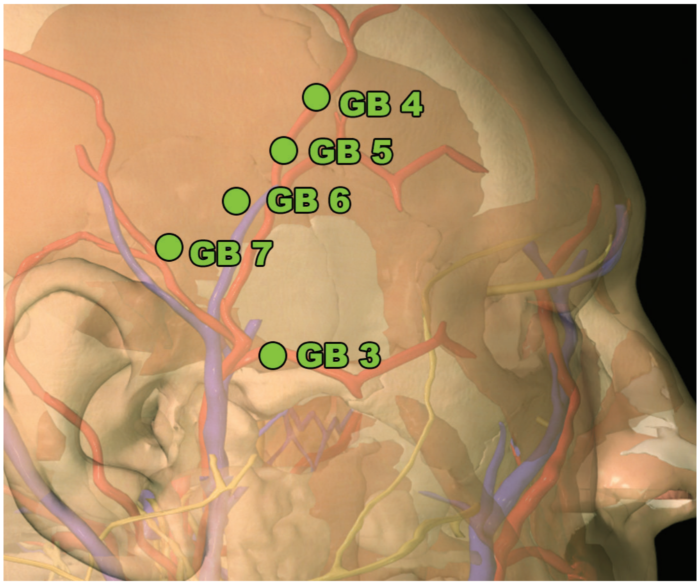

Figure 11-12. GB 4 through GB 7 line up along the superficial temporal vessels, apparent here through the semi-transparent skin layer.

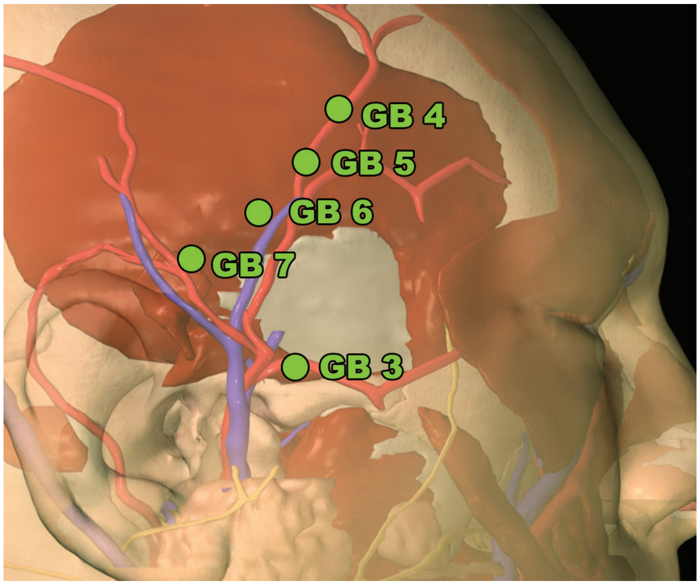

Figure 11-13. Descriptive names for GB 4, "Forehead Fullness" and "Jaw Stretching" allude to the structure and function, respectively, of the temporalis muscle.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[3] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can occur at GB 4 and elsewhere along the neurovascular course. Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[4]

Vessels

- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.
- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.

Clinical Relevance: Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 4, considering the limited responses to conventional methods often seen.[5]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and parotid arteries.[6]

Indications and Potential Point Combinations

- **Eyestrain and tension around the eyes:** GB 4, tender trigger points in the temporalis and orbicularis oculi muscles.
- **Dry eye:** GB 4, GB 20, TH 23, BL 2, ST 1, Taiyang, GV 23, SP 3, LU 9, LU 10, HT 8.[7]
- **Dizziness:** GB 4, SI 19, GB 20, GV 24.5 (Yintang), GV 20.
- **Toothache:** Rule out odontalgia radiating from the temporalis muscle.

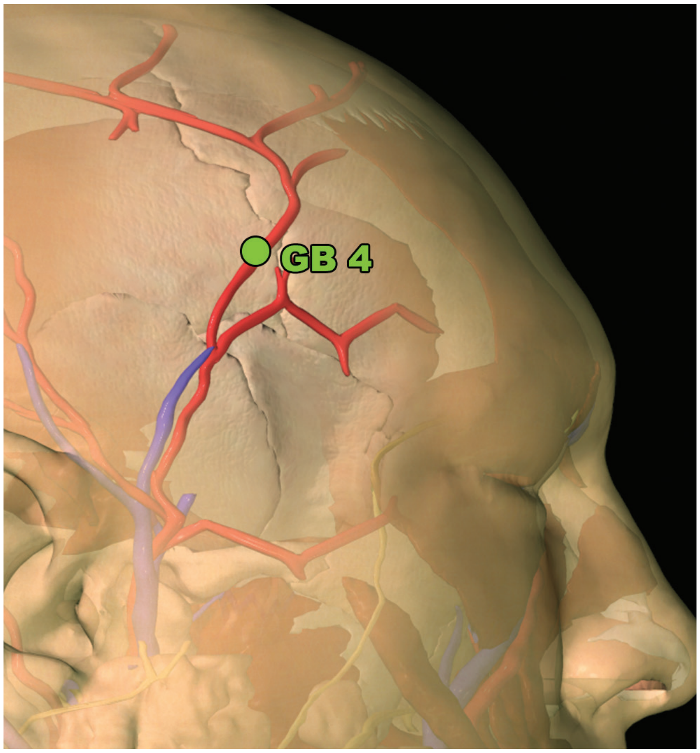

Figure 11-14. As is the case with many other points on the calvarium, GB 4 lands close to or directly over a suture; this point relates to the coronal suture. Most cranial sutures harbor neurovascular elements that respond to neuromodulation. In addition, chronic headache sufferers may exhibit tenderness to palpation over one or more cranial sutures.

facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supra-orbital, deep temporal, buccal and parotid arteries.[7]

Indications and Potential Point Combinations

- **Eyestrain and tension around the eyes:** GB 5, tender trigger points in the temporalis and orbicularis oculi muscles.
- **Dizziness:** GB 5, SI 19, GB 20, GV 24.5 (Yintang), GV 20.
- **Toothache:** Rule out odontalgia radiating from the temporalis muscle, consider adding GB 5 if tender.
- **Headache at the vertex:** Palpate for trigger points in the intermediate (middle) portion of the temporalis muscle that extend in a fingerlike shape and direction toward the midline. Add GV 20 and local GV, GB, and BL points as necessary.

Evidence-Based Applications

- Needling GB 5 through to GB 8 or GB 8 to Taiyang, supplemented by points GB 20, TH 3, and GB 43, effectively reduced **migraine pain.**[2]
- Acupuncture applied to GB 5, ST 8, GB 20, GV 14, and LU 7 reduced the incidence and associated costs of **migraine without aura.**[8]
- One month of acupressure treatment at trigger points such as GB 5, BL 2, GB 20, GB 20, and TH 21 significantly reduced **chronic headache** for six months.[9]

GB 6

Xuan Li "Suspended Hair", or "Suspended Tuft"

On the temporal region, caudal to the natural hairline, 3/4 the distance from ST 8 to GB 7; 2 cun caudal to GB 4 on the curved line connecting GB 7 and ST 8. Midway between GB 5 and GB 7.

Muscles

- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: The temporalis muscle, a common source of pain and dysfunction affecting the temporomandibular joint, fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.[1]

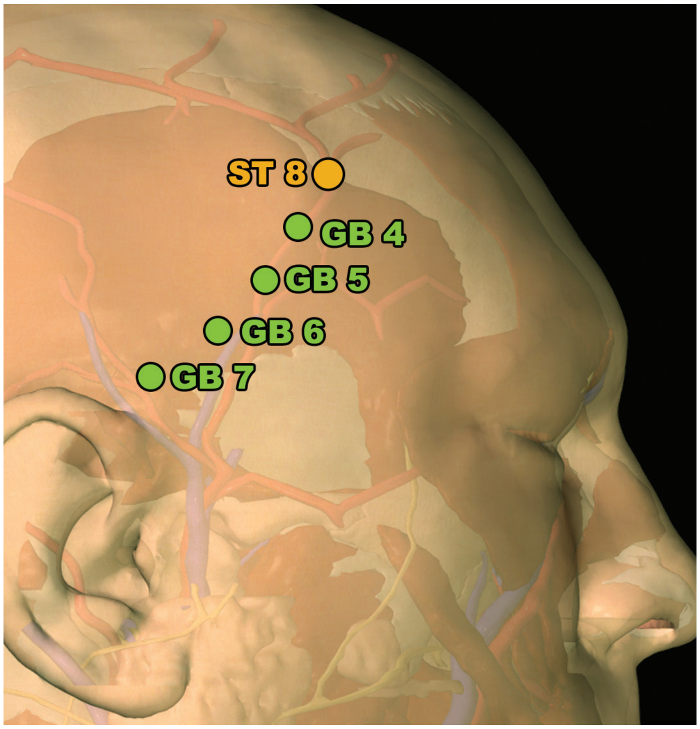

Figure 11-19. The name "Suspended Hair" or "Suspended Tuft" corresponds to the finding that when one locates this point on a patient with a full head of hair, one usually needs to lift a section of hair here. That tuft of hair typically remains elevated at GB 6 instead of falling back into its usual position.

Nerves

- **Anterior and posterior deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.
- **Auriculotemporal nerve (CN V_3):** Provides sensory innervation to the parotid gland. Provides sensation to the skin anterior to the ear and posterior temporal region, the tragus and part of the helix of the auricle, the roof of the exterior auditory meatus, and the upper tympanic membrane.
- **Facial nerve (CN VII), temporal branch:** Supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior portion of the orbicularis oculi muscle.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects the head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. Neuromodulation of nerves supplying the TMJ, local musculature, and nearby vessels provides analgesia and alleviates myofascial dysfunction for this craniomandibular disorder.

In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[2] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck thus constitutes a differential diagnosis for pain in the ear and TMJ.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[3] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can occur at GB 6 and elsewhere along the neurovascular course.

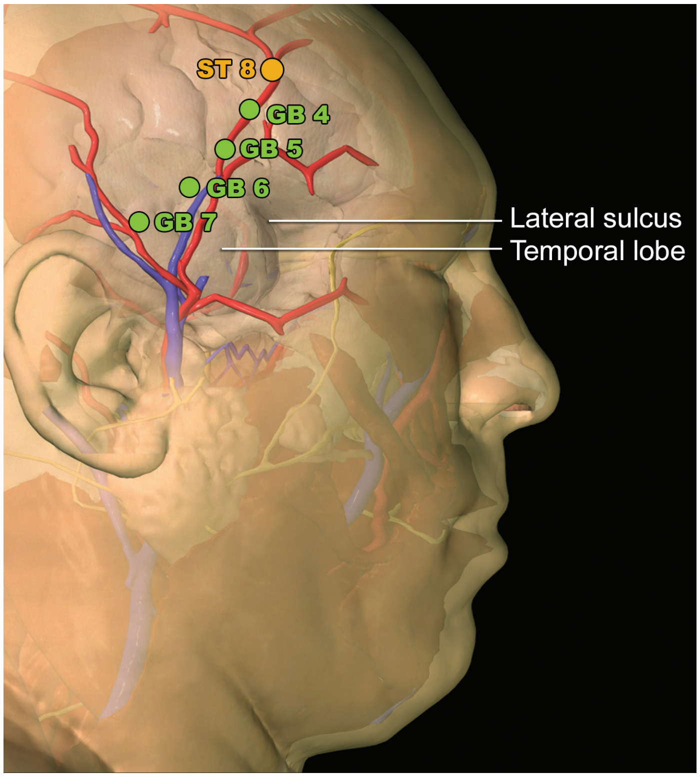

Figure 11-20. GB 6 locates, at least in this individual, the temporal lobe near the lateral sulcus of the brain.

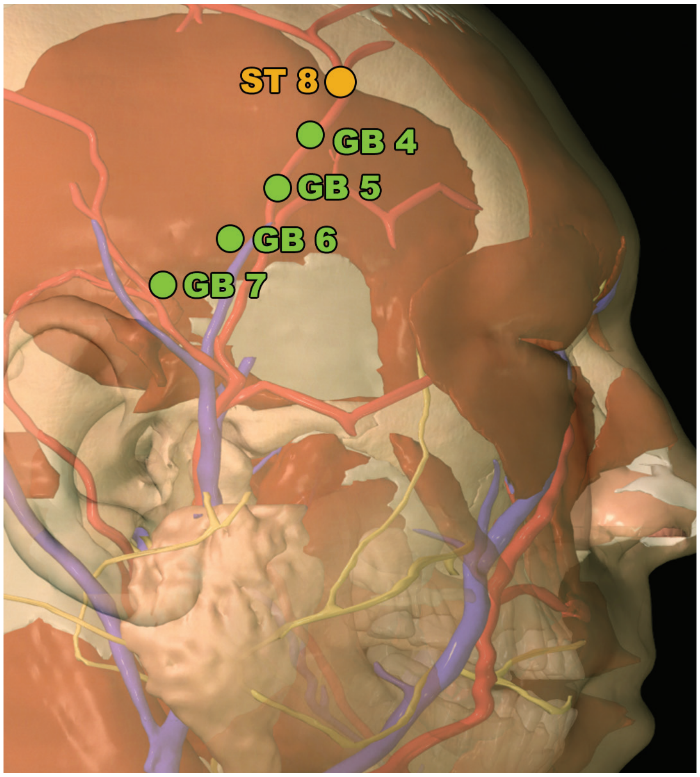

Figure 11-21. The temporalis muscle's ATrP's that refer pain to the teeth, face, and midline typically lie at the muscle-tendon interface, shown here just below GB 6.

Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[4]

Vessels

- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.
- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.

Clinical Relevance: Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 6, considering the limited responses to conventional methods often seen.[5]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supra-orbital, deep temporal, buccal and parotid arteries.[6]

Indications and Potential Point Combinations

- **Eyestrain and tension around the eyes:** GB 6, TH 23, BL 2, and tender trigger points in the temporalis and orbicularis oculi muscles.
- **Dizziness:** GB 6, SI 19, GB 20, GV 24.5 (Yintang), GV 20.
- **Toothache:** Rule out myofascial source of odontalgia; i.e., radiating pain from the temporalis muscle along its anterior ATrP's.

Within the natural hairline, dorsal and rostral to the auricle, level with and approximately one fingerbreadth rostral to TH 20.

Muscles

- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: The temporalis muscle, a common source of pain and dysfunction affecting the temporomandibular joint, fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.[1]

Nerves

- **Auriculotemporal nerve (CN V$_3$):** Provides sensory innervation to the parotid gland. Provides sensation to the skin anterior to the ear and posterior temporal region, the tragus and part of the helix of the auricle, the roof of the exterior auditory meatus, and the upper tympanic membrane.
- **Facial nerve (CN VII), temporal branch:** In this region, supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior portion of the orbicularis oculi muscle.
- **Anterior and posterior deep temporal nerves (CN V$_3$):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects the head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. Neuromodulation of nerves supplying the TMJ, local musculature, and nearby vessels provides analgesia and alleviates myofascial dysfunction for this craniomandibular disorder.

In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[3] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck thus constitutes a differential diagnosis for pain in the ear and TMJ.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[4] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can occur at GB 7 and elsewhere along the neurovascular course. Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[5]

The auriculotemporal nerve also impacts balance. Stomatognathic disorders, i.e., problems with mouth, teeth, mandible,

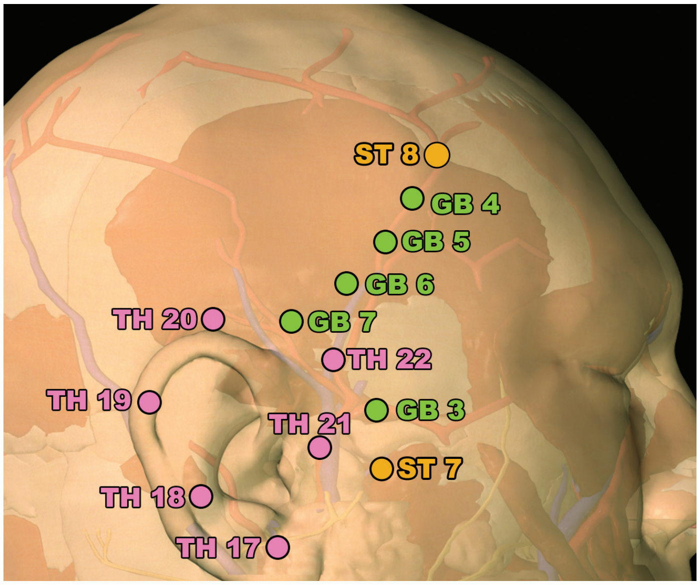

Figure 11-23. The name for GB 7, "Temporal Hairline Curve" speaks to its topographical location along the natural hairline. When the head lacks hair is in this situation, the alternate method of finding the point comes in handy; i.e., find the site level with and approximately one fingerbreadth rostral to TH 20. The vascular correlates of the intersecting GB, TH, and ST lines (i.e., the superficial temporal and posterior auricular vessels) branch off of the external carotid vessels. This vasculature is more readily visible in Figure 11-24.

Figure 11-25A. GB 7 and TH 20 live at approximately the same level but GB 7 will affect different trigger points in the temporalis muscle than will TH 20. Palpate your own GB 7 and TH 20. Do you have taut bands in both locations? Many patients do as well. This exercise illustrates the imperative of including informed palpation in acupuncture and related techniques as a fundamental first step in diagnosis before deciding upon treatment protocols.

pharynx, and other structures associated with mastication, speech, and deglutition, negatively impact posture, balance, and gait.[2]

Muscle reflex responses controlling balance and equilibrium depend on input into the reticular formation from several sources. Afferents arise from trigeminal, auditory, proprioceptive, visual, vestibular, cutaneous, and autonomic pathways. The extensive reticular formation in the brainstem integrates this information, couples it with input from the brain, and forwards it to brainstem nuclei that oversee sensation, motor activity, and autonomic function.

Afferent information reaching the nucleus raphe magnus in the reticular formation makes its way by means of the spinal tract of V. These input can influence reflex arcs and motor responses from the face and cranium.

Painful dentition and abnormal TMJ mechanics send afferent input that may sensitize neural pathways related to auriculotemporal nerve input. These facilitated reflexes between the reticulospinal and nucleus raphe magnus tracts may lead to involuntary rhythmic tremors, gait disturbances, and postural imbalance. In this way, afferent impulses transmitted through trigeminal nerve circuitry have the capacity to change tonic or “resting” activity within the reticular formation.

Altered tonic activity impacts the nature of eye movements, posture, respiration, arousal, sleep, pain, vasomotor tone, cardiac output, feeding, and homeostasis in general.

Taking all of these reflexes into account, trigeminal nerve input conveyed through the auriculotemporal nerve works alongside sensory, oculomotor, and vestibular afferents to manage a variety of highly coordinated activities.

Vessels

- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible.

Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.

- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.
- **Posterior auricular artery:** This small branch of the external carotid artery ascends between the external acoustic meatus and the mastoid process. Its distribution includes the nearby muscles, parotid gland, facial nerve, auricle, scalp, and structures in the temporal bone.
- **Posterior auricular vein:** The posterior auricular vein not only drains the scalp posterior to the auricle, but it also often receives a mastoid emissary vein from the sigmoid sinus, which is one of the dural venous sinuses.
- **Deep temporal arteries and veins:** Supply and drain the temporalis muscle.

Clinical Relevance: Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 7, considering the limited responses to conventional methods often seen.[6]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and parotid arteries.[7]

The posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization offers one alternative to pharmacotherapy,[8] it seems unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear, from GB 7/TH 20 to TH 17. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

Indications and Potential Point Combinations

- **Eyestrain and tension around the eyes:** GB 7, GB 1, TH 23, BL 2, and tender trigger points in the temporalis and orbicularis oculi muscles.
- **Dizziness:** GB 7, SI 19, GB 20, GV 24.5 (Yintang), GV 20.
- **Toothache:** Rule out odontalgia radiating from the temporalis muscle along its anterior ATrP’s. Consider GB 7, GB 6, TH 23, LI 4, LU 7.
- **Headache:** When radiating to the midline from temporalis, palpate for trigger points, consider adding GB 7 if tender to palpation.

Evidence-Based Applications

- Electroacupuncture applied to the right-sided GB 7 and GV 20 in patients recovering from ischemic stroke changed glucose metabolism significantly in the following brain regions: primary motor area, premotor cortex, superior parietal lobule (bilateral) and supplemental motor area on the unaffected hemisphere immediately after electroacupuncture treatment. Longstanding glucose metabolism changes lasted three weeks after daily electroacupuncture stimulation and took place in the bilateral primary motor areas and superior parietal lobules. Glucose metabolism in the insula, putamen, and cerebellum were also altered significantly. These findings implicate electroacu-

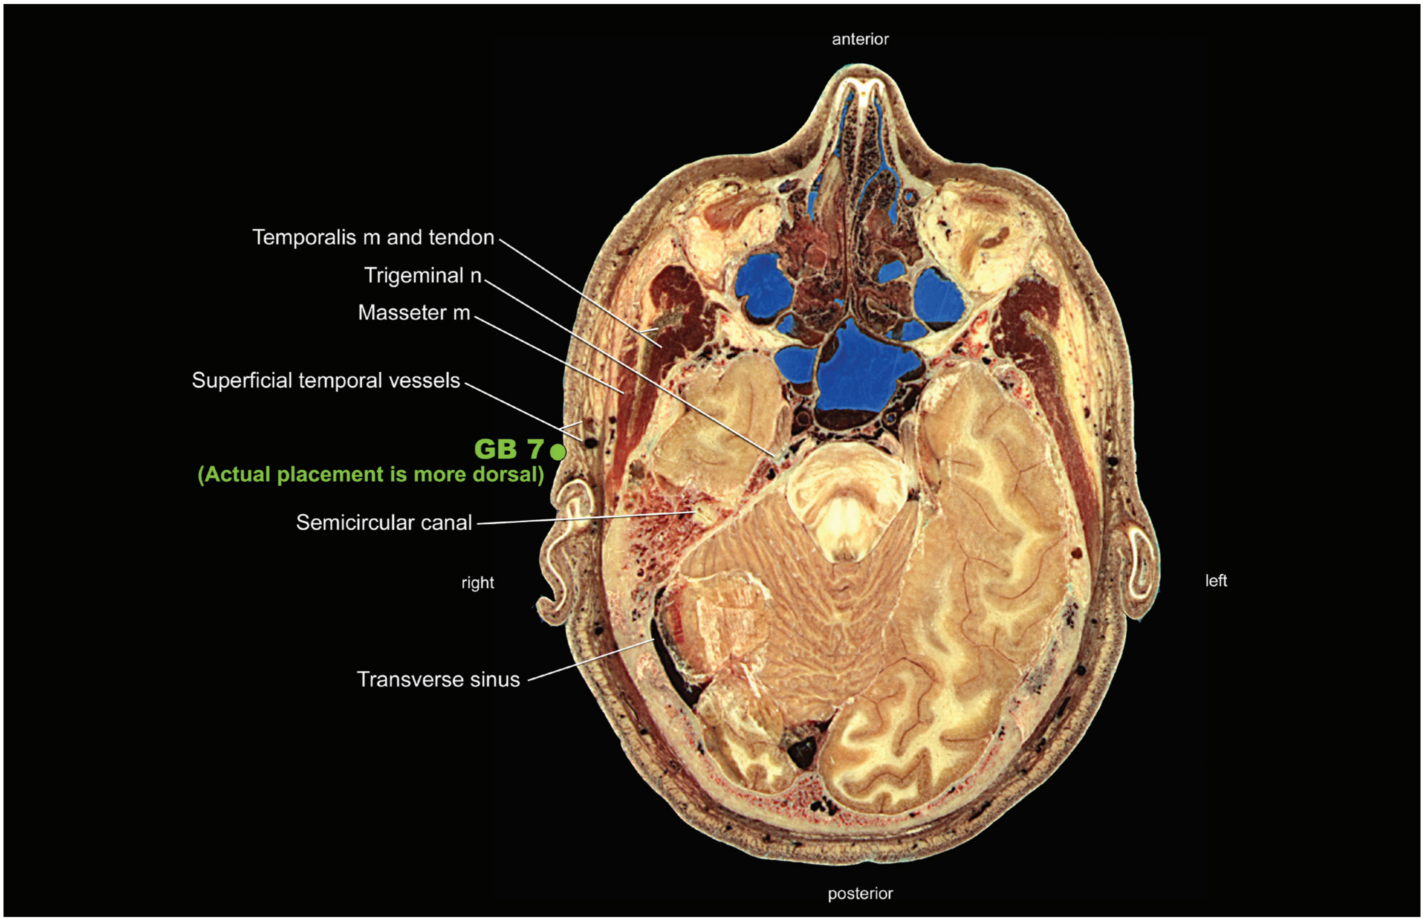

Figure 11-25B. This cross section illustrates the proximity of the semicircular canals to the extracranial site just caudal to GB 7. The semicircular canals process information about balance. The auriculotemporal nerve (near GB 7 as well) provides extracranial afferent input via the trigeminal nerve and the spinal tract of V. Both sources of neural stimulation help maintain equilibrium.

puncture at GB 7 and GV 20 as **influencing cerebral motor plasticity following ischemic stroke.**[9]

- Treatment of **vertigo induced by vertebrobasilar insufficiency** included the following points targeted in a "penetrating needle" fashion (i.e., threading from one location to another): GV 20 toward GV 21, GB 8 to GB 7, BL 9 toward BL 10, stimulated further with electroacupuncture. Activating points in this manner outperformed treatment selected according to TCM metaphors.[10]

GB 8

Shuai Gu “Leading Valley”

On the temporal region, in a small depression 1 cun dorsal to the apex of the auricle and TH 20. Located 1.5 cun inside the hairline where a bulge forms when the teeth clench.

Muscles

- **Superior auricular muscle:** The superior auricular muscle wiggles the ear. It is larger than the rostral (anterior) and caudal (posterior) auricular muscles, but also thin and fan-shaped. The fibers of the superior auricular muscle arise from the galea aponeurotica and converge to create a flat tendon that inserts onto the upper portion of the cranial aspect of the auricle.
- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: The superior auricular muscle, like its larger neighbor, the temporalis muscle, exhibits a fan pattern to its fibers. As such, the distribution of central trigger points in either muscle similarly arrange in a fan-like array rather than a straight line.

A common source of pain and dysfunction affecting the temporomandibular joint,[1] the temporalis muscle fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible.

Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.

Nerves

- **Auriculotemporal nerve (CN V_3):** Provides sensory innervation to the parotid gland. Provides sensation to the skin anterior to the ear and posterior temporal region, the tragus and part of the helix of the auricle, the roof of the exterior auditory meatus, and the upper tympanic membrane.
- **Facial nerve (CN VII), temporal branch:** In this region, supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior portion of the orbicularis oculi muscle.
- **Anterior and posterior deep temporal nerves (CN V_3):** Provide motor to the temporalis muscle. They branch off of the anterior division of the mandibular portion of the CN V.
- **Greater occipital nerve (C2, C3):** Supplies sensation to the skin from the occiput to the vertex. Arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The dorsal roots of C1-C3 also supply sensation to the posterior cranial fossa, along with the vagus nerve.

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects the head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. Neuromodulation of nerves supplying the TMJ, local musculature, and nearby vessels provides analgesia and alleviates myofascial dysfunction for this craniomandibular disorder.

In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[6] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck thus constitutes a differential diagnosis for pain in the ear and TMJ.

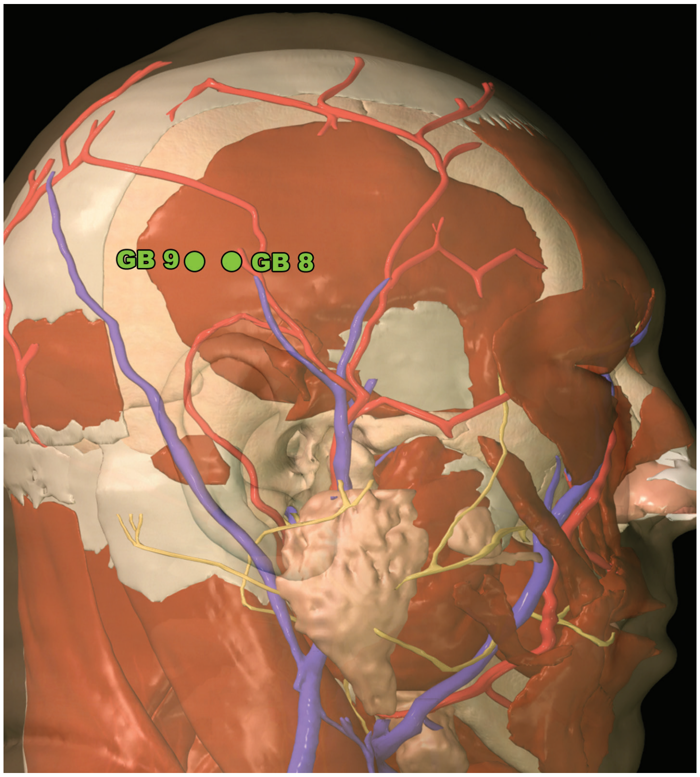

Figure 11-26. GB 8 and GB 9 identify locations where taut bands arise in the Horizontal, caudal part of the temporalis muscle. Find GB 8 where a bulge appears when the teeth tightly clench. Trigger points here refer pain to the parietal region and midline of the head.

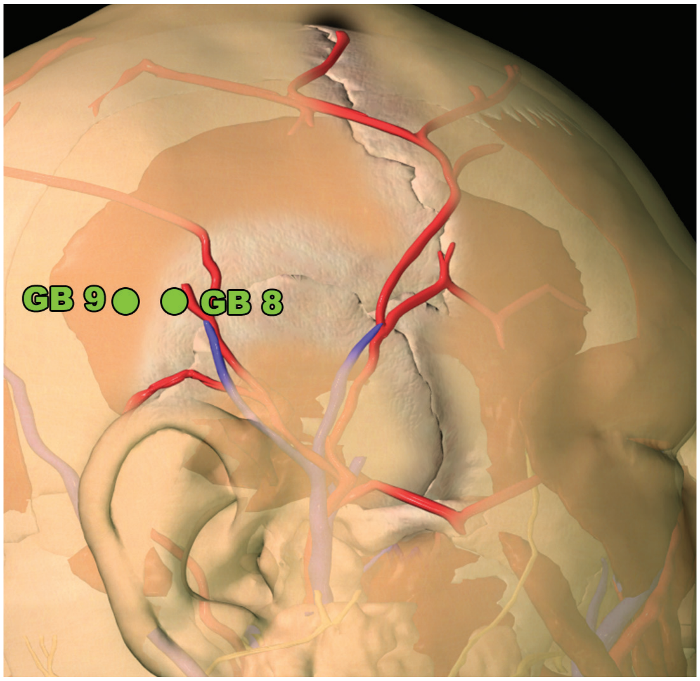

Figure 11-27. Tenderness to palpation at GB 8 may reflect not only myofascial dysfunction in the temporalis muscle but also cranial dysfunction in the temporoparietal suture. The suture appears adjacent to GB 8 in this lateral image. Alternate names for GB 8 such as "Following the Bone" or "Following the Corner" make more sense when seeing the suture and its "corner" near the point.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[7] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can occur at GB 8 and elsewhere along the neurovascular course. Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[8]

The auriculotemporal nerve also impacts balance. Stomatognathic disorders, i.e., problems with mouth, teeth, mandible, pharynx, and other structures associated with mastication, speech, and deglutition, negatively impact posture, balance, and gait.[2]

Muscle reflex responses controlling balance and equilibrium depend on input into the reticular formation from several sources. Afferents arise from trigeminal, auditory, proprioceptive, visual, vestibular, cutaneous, and autonomic pathways. The extensive reticular formation in the brainstem integrates this information, couples it with input from the brain, and forwards it to brainstem nuclei that oversee sensation, motor activity, and autonomic function.

Afferent information reaching the nucleus raphe magnus in the reticular formation makes its way by means of the spinal tract of V. These input can influence reflex arcs and motor responses from the face and cranium.

Painful dentition and abnormal TMJ mechanics send afferent input that may sensitize neural pathways related to auriculotemporal nerve input. These facilitated reflexes between the reticulospinal and nucleus raphe magnus tracts may lead to involuntary rhythmic tremors, gait disturbances, and postural imbalance. In this way, afferent impulses transmitted through trigeminal nerve circuitry have the capacity to change tonic or "resting" activity within the reticular formation.

Altered tonic activity impacts the nature of eye movements, posture, respiration, arousal, sleep, pain, vasomotor tone, cardiac output, feeding, and homeostasis in general.

Taking all of these reflexes into account, trigeminal nerve input conveyed through the auriculotemporal nerve works alongside sensory, oculomotor, and vestibular afferents to manage a variety of highly coordinated activities.

The GON ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. The GON becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[9] As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.

Convergent input between the GON and the trigeminal nerve supplying the rostral epicranium may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck.[3,4] That is, crosstalk between the GON and the trigeminal nerve along with windup in the trigeminocervical complex in the brainstem and cervical cord can cause both intracranial and extracranial sources of discomfort. Stimulation of the GON through acupuncture and related techniques can reduce pain from headaches that arise in trigeminal nerve territory, likely through mechanisms involving trigemino- cervical convergence at the level of the trigeminal nucleus caudalis.[10]

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[11] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[12] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[13,14]

In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[15] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia,

Figure 11-28. The "valley" referred to by the descriptive name for GB 8, "Valley Lead", could refer to the valley created by the brain deep to this site. The lateral temporal, or Sylvian fissure, will lead to the insula. Targeting the insula with transcranial laser therapy could possibly affect this small area of cortex involved in perpetuating addictive behaviors. The insula has been considered a "critical neural substrate" to smoking addiction.[22]

but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[16] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[17]

Vessels

- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.
- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.
- **Deep temporal arteries and veins:** Supply and drain the temporalis muscle.

Clinical Relevance: Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 8, considering the limited responses to conventional methods often seen.[18]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and parotid arteries.[19]

The posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization offers one alternative to pharmacotherapy,[20] it seems unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear, from GB 8/ TH 20 to TH 17. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

Indications and Potential Point Combinations

- **Headache:** When the headache radiates to the midline from the temporalis muscle, palpate for trigger points, consider adding GB 8 or GB 9 if tender to palpation.
- **Dizziness:** GB 8, GB 7, SI 19, GB 20, GV 24.5 (Yintang), GV 20.
- **Persistent nausea and vomiting:** GB 8, PC 6, GV 20, ST 36, SP 6.
- **Smoking cessation:** GB 8, GB 18, HT 7.

Evidence-Based Applications

- Needling GB 5 through to GB 8 or GB 8 to Taiyang, supplemented by points GB 20, TH 3, and GB 43, effectively reduced **migraine** pain.[5]
- A mixture of acupuncture plus oral administration of Chinese herbs effectively treated **migraine**.[21] Points included GB 8, GB 20, GV 20, LR 2, PC 6, and SP 6 as well as loci that exhibited tenderness to palpation.

GB 9

Tian Chong "Heavenly Rushing", "Celestial Passage", or "Celestial Hub"

On the temporal region, 2 cun within the hairline, posterior and superior to the root of the auricle, about .5 cun posterior to GB 8, in a small depression. Compare the placement of GB 8 and GB 9 in the cross section appearing in Figure 11-28.

Muscles

- **Superior auricular muscle:** The superior auricular muscle wiggles the ear. It is larger than the rostral (anterior) and caudal (posterior) auricular muscles, but also thin and fan-shaped. The fibers of the superior auricular muscle arise from the galea aponeurotica and converge to create a flat tendon that inserts onto the upper portion of the cranial aspect of the auricle.
- **Temporalis muscle:** Closes the jaw by elevating the mandible. Retrudes the mandible after it protrudes.

Clinical Relevance: The superior auricular muscle, like its larger neighbor, the temporalis muscle, exhibits a fan pattern to its fibers. As such, the distribution of central trigger points in either muscle similarly arrange in a fan-like array rather than a straight line.

A common source of pain and dysfunction affecting the temporomandibular joint, the temporalis muscle fills the temporal fossa, overlying the adjoined zygomatic, frontal, parietal, sphenoid, and temporal bones. The temporalis muscle attaches onto the medial and lateral aspects of the coronoid process of the mandible as well as onto the anterior edge of the ramus of the mandible. Its extent almost reaches the last molar tooth. The temporalis muscle fibers fan out in a rostral-caudal direction like spokes of a wheel, collecting onto their mandibular attachment as they would onto a hub. This multi-directional circumstance allows the temporalis to move the mandible in a variety of directions to accommodate the motions required for chewing, speaking, yawning, etc. The rostral/vertical, middle/oblique, and caudal/horizontal bundles of these fibers form three functionally distinct portions with each group referring a different pain pattern when trigger points develop. That is, attachment trigger points (ATrPs) (i.e., those occurring at the musculotendinous junction) in the anterior division leads to a pain trajectory that arches over the supraorbital ridge, up to the forehead, and down to the ipsilateral nasal ala and upper incisor teeth. ATrPs in the middle and caudal sections refer pain upward toward the midline of the cranium in fingerlike projections aligned with the direction of the spokes, or muscle fibers. Normal chewing activates mainly the rostral fibers or a combination or rostral and middle. Jaw clenching, bruxism, chewing gum on one side with a strong lateral component disrupts normal mechanics, leading to overuse and development of myofascial restrictions.

Nerves

- **Auriculotemporal nerve (CN V$_3$):** Provides sensory innervation to the parotid gland. Provides sensation to the skin anterior to the ear and posterior temporal region, the tragus and part of the helix of the auricle, the roof of the exterior auditory meatus, and the upper tympanic membrane.
- **Facial nerve (CN VII), temporal branch:** In this region, supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior portion of the orbicularis oculi muscle.
- **Deep temporal nerve branches from the mandibular nerve (CN V$_3$):** Innervate the temporalis muscle.
- **Greater occipital nerve (C2, C3):** Supplies sensation to the skin from the occiput to the vertex. Arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The dorsal roots of C1-C3 also supply sensation to the posterior cranial fossa, along with the vagus nerve. Convergent input between the greater occipital nerve and the trigeminal nerve (which supplies the anterior and middle cranial fossa may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck.[1,2]

Clinical Relevance: Pain from myofascial and temporomandibular (TMJ) sources affects the head and neck; much of this pain results from somatic dysfunction causing neuropathic pain by means of nerve entrapment or compression. Neuromodulation of nerves supplying the TMJ, local musculature, and nearby vessels provides analgesia and alleviates myofascial dysfunction for this craniomandibular disorder.

In addition to musculoskeletal problems, periauricular pain and TMJ discomfort may be caused by neoplasia, such as infiltrating carcinomas of the head and neck.[4] Neural anastomoses and communicating branches connecting the facial and trigeminal nerves create a conduit for perineural tumor spread. This type of tumor growth occurs fairly frequently in patients with either

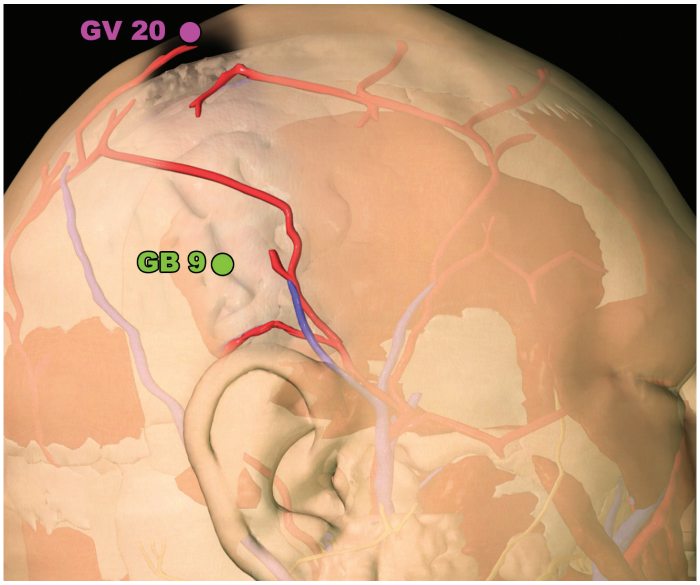

Figure 11-29. The term "Celestial Hub" for GB 9 refers to the relationship between GB 9, the "hub" in this case, and GV 20, a "celestial point" by dint of its relationship to mental-emotional processes. Too, GV 20 occupies the "sky" position on the metaphorical rim of a wheel outlined by the horizon of the calvarium depicted in this image. The direction that vessels take from GB 9 to GV 20 suggests a "rushing up" or "surge" from GB 9 to GB 20. Hence the names, "Heavenly Rushing" and "Celestial Passage". Specifically, as depicted here, the parietal branch of the superficial temporal artery "rushes" blood toward GV 20 along a "celestial passage".

adenoid cystic carcinoma or skin cancer afflicting the head or neck. The auriculotemporal nerve serves as one of several sites through which this spread occurs. Carcinoma of the head and neck thus constitutes a differential diagnosis for pain in the ear and TMJ.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[5] Its hitch-hiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can occur at GB 9 and elsewhere along the neurovascular course. Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[6]

The auriculotemporal nerve also impacts balance. Stomatognathic disorders, i.e., problems with mouth, teeth, mandible, pharynx, and other structures associated with mastication, speech, and deglutition, negatively impact posture, balance, and gait.

Muscle reflex responses controlling balance and equilibrium depend on input into the reticular formation from several sources. Afferents arise from trigeminal, auditory, proprioceptive, visual, vestibular, cutaneous, and autonomic pathways. The extensive reticular formation in the brainstem integrates this information, couples it with input from the brain, and forwards it to brainstem nuclei that oversee sensation, motor activity, and autonomic function.

Afferent information reaching the nucleus raphe magnus in the reticular formation makes its way by means of the spinal tract of V. These input can influence reflex arcs and motor responses from the face and cranium.

Painful dentition and abnormal TMJ mechanics send afferent input that may sensitize neural pathways relatedto auriculotemporal nerve input. These facilitated reflexes between the reticulospinal and nucleus raphe magnus tracts may lead to involuntary rhythmic tremors, gait disturbances, and postural imbalance. In this way, afferent impulses transmitted through trigeminal nerve circuitry have the capacity to change tonic or "resting" activity within the reticular formation.

Altered tonic activity impacts the nature of eye movements, posture, respiration, arousal, sleep, pain, vasomotor tone, cardiac output, feeding, and homeostasis in general.

Taking all of these reflexes into account, trigeminal nerve input conveyed through the auriculotemporal nerve works alongside sensory, oculomotor, and vestibular afferents to manage a variety of highly coordinated activities.

The GON ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. The GON becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[7] As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.

Convergent input between the GON and the trigeminal nerve supplying the rostral epicranium may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck. That is, crosstalk between the GON and the trigeminal nerve along with windup in the trigeminocervical complex in the brainstem and cervical cord can cause both intracranial and extracranial sources of discomfort.

Stimulation of the GON through acupuncture and related techniques can reduce pain from headaches that arise in trigeminal nerve territory, likely through mechanisms involving trigemino- cervical convergence at the level of the trigeminal nucleus caudalis.[8]

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[9] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[10] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[11,12]

In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[13] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[14] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[15]

Functional brain imaging reveals how neuromodulation affects cerebral activation levels, whether the stimulation arrives by cranial, spinal, or peripheral neural avenues. Functional magnetic resonance imaging (fMRI) research evaluating the effects of acupuncture on the brain has compared stimulation of scalp and body loci. Findings expose unique signal activations between the two groups, most likely resulting from the different afferent endings stimulated by each approach.[16] The scalp acupuncture group (needled at left-side only TH 20, GB 18, GB 9, and Sishencong) demonstrated more activity in the contralateral somatosensory association cortex, the postcentral gyrus, and the parietal lobe as compared to the limb acupuncture group, who received treatment at right-side only LI 1, LI 10, LR 3, and

ST 36. Perhaps unsurprisingly, the latter points produced activation in the right occipital lobe, lingual gyrus, visual association cortex, right parahippocampal gyrus, limbic lobe, hippocampus, left anterior lobe, culmen, and cerebellum.

Vessels

- **Posterior auricular artery:** This small branch of the external carotid artery ascends between the external acoustic meatus and the mastoid process. Its distribution includes the nearby muscles, parotid gland, facial nerve, auricle, scalp, and structures in the temporal bone.
- **Posterior auricular vein:** The posterior auricular vein not only drains the scalp posterior to the auricle, but it also often receives a mastoid emissary vein from the sigmoid sinus, which is one of the dural venous sinuses.
- **Superficial temporal artery:** Arises from the external carotid artery and ascends anterior to the ear, to the temporal region; ends in the scalp. Provides blood circulation to the facial muscles and the skin of the frontal and temporal regions.
- **Superficial temporal vein:** This vein arises from the widespread plexus of veins on the scalp's lateral aspect and along the zygomatic arch. The superficial temporal vein drains blood from the side of the scalp, the superficial portions of the temporal muscle, and the external ear.
- **Deep temporal arteries and veins:** Supply and drain the temporalis muscle.

Clinical Relevance: The posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization offers one alternative to pharmacotherapy,[17] it seems unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

Indications and Potential Point Combinations

- **Headache:** When the headache radiates to the midline from the temporalis muscle, palpate for trigger points, consider adding GB 8 or GB 9 if tender to palpation.
- **Dizziness:** GB 9, GB 7, SI 19, GB 20, GV 24.5 (Yintang), GV 20.
- **Persistent nausea and vomiting:** GB 9, PC 6, GV 20, ST 36, SP 6.
- **Ear wiggling disorder affecting the auricularis superior muscle:**[3] GB 9, GB 8, TH 17.

GB 10

Fu Bai "Floating White"

On the temporal region, posterior to the auricle and superior to the mastoid process, at the junction of the upper and middle thirds of a curved line running parallel to the rim of the ear and within the hairline that connects GB 9 and GB 12. Note its relationship to GB 9 and GB 12 as demarcated in Figure 11-30A.

Connective Tissues

- **Galea aponeurotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as that near GB 10, as well as deactivating trigger points in the frontalis (e.g., GB 14) and the occipitalis (e.g., BL 9) muscles. Figure 11-30A depicts the relationship of GB 10 to the galea aponeurotica and the occipital belly of the epicranius ("occipitialis" m). Lateral pulls from the temporalis fascia accentuate tension in the epicranial aponeurosis and predisposes patients to headache syndromes.

Clinical Relevance: GB 10 can become tender to palpation with occipitofrontalis tension (e.g., in cases of tension headache) that results in traction on the epicranial aponeurosis. GB 10 also becomes tender in some patients suffering from migraine and chronic neck pain. In addition, many muscles refer pain to the occipital region when they harbor trigger points. These muscles include the trapezius, sternocleidomastoid, semispinalis, splenius, suboccipital group, occipitalis, digastric and temporalis.

Nerves

- **Posterior auricular nerve (from the facial nerve, CN VII):** Supplies the auricularis posterior muscle and the occipital belly of the occipitofrontalis muscle.
- **Great auricular nerve (ventral rami of C2, C3):** This branch of the cervical plexus emerges from the posterior triangle of the neck. It courses parallel to the external jugular vein, then branches to provide sensation to the skin over the parotid gland, mastoid process, and pinna. Specifically, the great auricular nerve supplies the lobule and antitragus. It sometimes acts alone to supply sensation to the tragus; other times it shares this function with the auriculotemporal nerve.[4] The great auricular nerve also usually innervates the tail of the helix and the scapha. It also supplies sensation to the skin overlying the angle of the mandible. Communicates with the transverse cervical nerve, the cervical branch of the facial nerve, and the marginal mandibular nerve.[5] The great auricular nerve may issue a mastoid branch to that communicates with the lesser occipital nerve.
- **Lesser occipital nerve (ventral rami of C2, C3):** Supplies the skin over its course that runs from the posterior border of the SCM to the occiput; communicates with the greater occipital nerve. Lesser occipital nerve pain typically appears after physical exertion.[6]
- **Greater occipital nerve, or Arnold's nerve (dorsal rami of C2, (C3)):** This medial branch of the dorsal ramus of predominantly the C2 spinal nerve constitutes the greater occipital nerve; fibers from C3 may join in. It provides sensation to the skin from the occiput to the vertex and crosstalks with the lesser and third (least) occipital nerves.[1] The dorsal roots of C1-C3 also supply sensation to the posterior cranial fossa, along with the vagus nerve. Convergent input between the greater occipital nerve and the trigeminal nerve (which supplies the anterior and middle

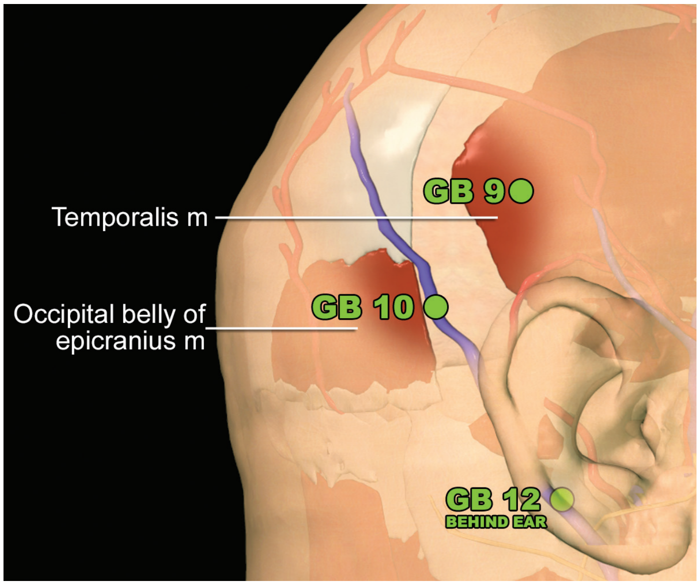

Figure 11-30A. A trigger point in the occipital belly of the epicranius muscle, otherwise known as the occipitalis muscle, refers pain to the ipsilateral parietal region and eye. The term "Floating White" may correspond to the epicranial aponeurosis. Or, this descriptive title for GB 10 may speak to the absence of muscle at this site altogether. This image illustrates the "in-between" location of GB 10, "floating" between myofascial elements atop the whiteness of the calvarium.

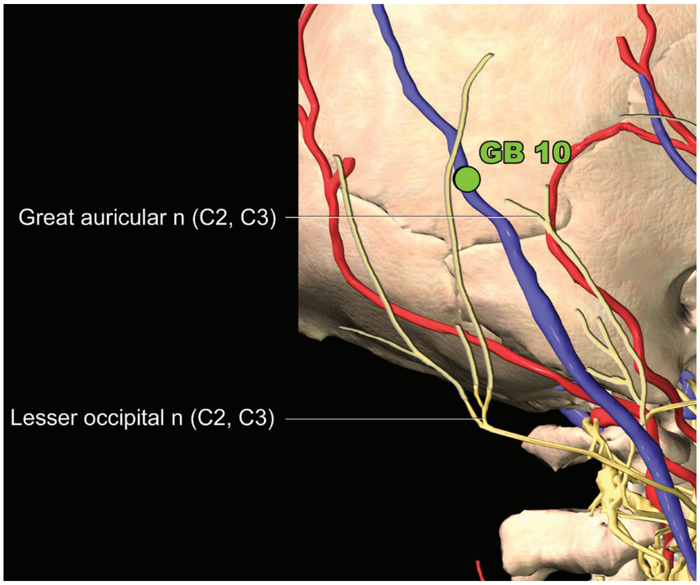

Figure 11-30B. The great auricular nerve and the lesser occipital nerve supply the integument in the vicinity of GB 10. The lesser occipital nerve communicates with the greater occipital nerve, and neuropathy of either can lead to headache. Peripheral stimulation of the occipital nerves has become more widely accepted for intractable chronic cluster headache.[21] While some practitioners implant electrodes in the suboccipital region to treat chronic headache, acupuncture and related techniques offer a much less invasive alternative.

cranial fossa may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck.[2,3]

The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[7] As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.

Clinical Relevance: One of the risks of having a facelift performed involves nerve damage; injury to the great auricular nerve happens in about 7% of patients.[8] This nerve courses over the mid-body of the SCM where it bifurcates into anterior and posterior (or rostral and caudal) branches and its terminal arborization. Rhytidectomy surgery involving revision of cervical folds may damage the great auricular nerve and cause loss of sensation caudal to the ear. Nerve stimulation in this zone may facilitate return of sensation, depending on the type of nerve damage induced.

Extracranial nerves of the caudal portion of the head such as the posterior auricular nerve or lesser occipital undergo entrapment and compression as a result of myofascial restriction in the SCM muscle or occipitofrontalis, producing a variety of headache patterns.[9]

This region also receives sensory nerve supply from the greater occipital nerve (GON). Crosstalk between the GON and the trigeminal nerve and windup in the trigeminocervical complex in the brainstem and cervical cord supports the inclusion of BL 9 in point protocols addressing intracranial and extracranial sources of discomfort.

Stimulation of the GON can reduce pain from headaches that arise in trigeminal nerve territory, likely through mechanisms involving trigemino-cervical convergence at the level of the trigeminal nucleus caudalis.[1,10]

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[11] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[12] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[13,14]

In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[15] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[16] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[17]

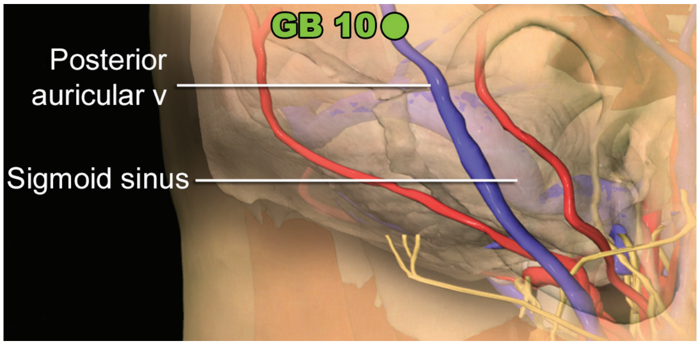

Figure 11-31. The posterior auricular vein beneath GB 10 connects to the sigmoid sinus, a dural venous sinus, via a mastoid emissary vein (not shown).

Vessels

- **Posterior auricular artery:** Begins at the external carotid artery and courses posteriorly, deep to the parotid gland, and migrates along the styloid process between the ear and the mastoid process. Nourishes the scalp posterior to the auricle, as well as the auricle itself.
- **Posterior auricular vein:** Drains the scalp posterior to the auricle. The posterior auricular vein often receives blood from the sigmoid sinus (a dural venous sinus) via the mastoid emissary vein.
- **Occipital artery (a branch of the external carotid artery):** Supplies the scalp at the back of the head.
- **Occipital vein:** Usually drains into the suboccipital venous plexus or the internal jugular vein.

Clinical Relevance: True to its name as "spasm vessel" or "tugging vessel", the posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization represents one alternative to pharmacotherapy,[18] it seems unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact

Figure 11-32. Typical indications for GB 10 include headache, movement disorders, and visual disturbances. A local source of extracranial head pain involves myofascial trigger points in the occipitalis muscle. Intracranial sources of pain include dural irritation. Applications for movement disorders and visual problems correspond to the nearby cerebellar and occipital portions of the brain. These intracerebral sites offer access through transcranial laser therapy or reflexive neuromodulation by means of acupuncture.

reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

The occipital artery is often a main feeding artery in cases of intracranial dural arteriovenous fistulae.[19] Also, blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[20] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

Indications and Potential Point Combinations

- **Headache from local myofascial dysfunction:** GB 10, GV 20, GV 19, BL 10, tender myofascial trigger points.
- **Cluster headache:** GB 10, BL 10, GB 20, LI 4, Yintang, GV 20.
- **Epilepsy:** GB 10, GV 20, BL 10, BL 60, HT 3, ST 36, Yingtang.
- **Great auricular neuritis (non-infectious):** GB 10, GB 12, TH 18, TH 20.
- **Tinnitus:** Palpate for somatic dysfunction and trigger points in the temporalis, occipitalis, and suboccipital muscles. Ask the patient if pressure at any of these sites, including GB 10, reduces the intensity of the tinnitus. If so, consider a structural etiology and deactivate trigger points accordingly. Employ soft tissue therapy and myofascial release to improve fascial and structural mobility in the region, reducing pressure on the "sound system" of the ear, including the temporal bone in which it is housed.
- **Greater occipital neuralgia (Arnold's neuralgia), with pain extending from suboccipital locations to the vertex (GV 20):** GB 10, GB 19, GB 20, GB 21, BL 10, BL 9, GV 20.

GB 11

Tou Qiao Yin "Yin Portals of the Head"

On the temporal region, posterior to the auricle and to the superior ridge of the mastoid process, at the junction of the middle and lower thirds of a curved line running parallel to the rim of the ear and within the hairline that connects GB 9 and GB 12. Feel for the depression in which this point sits. Figure 11-34 examines the source of this depression at GB 11 along with the relationship between GB 11 and its neighboring points along the GB channel.

Muscles

- **Auricularis posterior muscle:** Retracts the auricle.
- **Splenius capitis muscle:** Working bilaterally, the splenius capitis muscles extend the head. Working unilaterally, the splenius capitis bends the head in a lateral direction.
- **Sternocleidomastoid (SCM) muscle:** Acting unilaterally, tilts the head laterally. Flexes the neck and rotates it so that the face turns superiorly to the opposite side. When acting bilaterally, the chin thrusts forward.

Clinical Relevance: Myofascial trigger points in any of the muscles in this region can lead to head and neck pain. In addition, pain at the back of the head can arise from trigger points in the multifidi, levator scapulae, splenius cervicis, and infraspinatus muscles. Restriction in the soft tissues in the neck elevates pressure on large, vital neural, vascular, and glandular components, raising the potential for pain and suboptimal endocrine regulation.

GB 11 abuts the posterior, or caudal auricular muscle. As such, neuromodulation at this site may benefit myofascial pathology not only in this muscle but fibers from the attachment of the SCM muscle as well, shown in Figure 11-33. Motor fibers from the accessory nerve (CN XII) exit the skull via the jugular foramen in close association with the vagus nerve, helping to explain the autonomic concomitants associated with SCM dysfunction.

Trigger points in this area radiate pain to the ear, the jaw, the chin, the vertex, the forehead, and the supraorbital ridge (eyebrow).

Nerves

- **Posterior auricular nerve (from the facial nerve, CN VII):** Supplies the auricularis posterior muscle and the occipital belly of the occipitofrontalis muscle.
- **Greater occipital nerve (C2, C3):** Supplies sensation to the skin from the occiput to the vertex. The dorsal roots of C1-C3 also supply sensation to the posterior cranial fossa, along with the vagus nerve. Convergent input between the greater occipital nerve and the trigeminal nerve (which supplies the anterior and middle cranial fossa may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck.[1,2]

The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[3] As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.

- **Lesser occipital nerve (C2, C3):** Supplies the skin behind the ear, the superior ear, the mastoid area, and possibly a small portion of the skin of the neck. May receive communicating branches from the greater occipital nerve. The lesser and greater occipital nerves pierce the trapezius at the base of the skull and are therefore subject to compression by cervical muscle tension, producing an occipital neuralgia. When this occurs, it may produce further cervical tension, perpetuating occipital head pain.
- **Greater auricular nerve (C2, C3):** Provides sensory innervation for the skin over the mastoid process, parotid gland, and pinna. Its anterior branch communicates with the facial nerve (CN VII) inside the substance of the parotid gland. The posterior branch communicates with the lesser occipital nerve, the auricular branch of the vagus, and the posterior auricular branch of the facial nerve.
- **Dorsal rami of upper cervical nerves:** Innervate the semispinalis capitis and splenius capitis muscles.
- **Spinal accessory nerve (CN XI):** Provides motor to the trapezius muscle.

Figure 11-33. GB 11 lands at the intersection of the occipital belly of the epicranius, the posterior auricular and SCM muscles.

- **Spinal nerves C2, C3, and C4**: Carry pain and proprioceptive information from the trapezius and sternocleidomastoid muscles.

Clinical Relevance: One of the risks of having a facelift performed involves nerve damage; injury to the great auricular nerve happens in about 7% of patients.[4] This nerve courses over the mid-body of the SCM where it bifurcates into anterior and posterior (or rostral and caudal) branches and its terminal arborization. Rhytidectomy surgery involving revision of cervical folds may damage the great auricular nerve and cause loss of sensation caudal to the ear. Nerve stimulation in this zone may facilitate return of sensation, depending on the type of nerve damage induced.

Extracranial nerves of the caudal portion of the head such as the posterior auricular nerve or lesser occipital undergo entrapment and compression as a result of myofascial restriction in the SCM muscle or occipitofrontalis, producing a variety of headache patterns.[5]

This region also receives sensory nerve supply from the greater occipital nerve (GON). Crosstalk between the GON and the trigeminal nerve and windup in the trigeminocervical complex in the brainstem and cervical cord supports the inclusion of GB 11 in point protocols addressing intracranial and extracranial sources of discomfort.

Stimulation of the GON can reduce pain from headaches that arise in trigeminal nerve territory, likely through mechanisms involving trigemino-cervical convergence at the level of the trigeminal nucleus caudalis.[1,6]

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[7] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[8] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[9,10]

In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[11] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[12] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[13]

Vessels

- **Posterior auricular artery:** Begins at the external carotid artery and courses posteriorly, deep to the parotid gland, and migrates along the styloid process between the ear and the mastoid process. Nourishes the scalp posterior to the auricle, as well as the auricle itself.

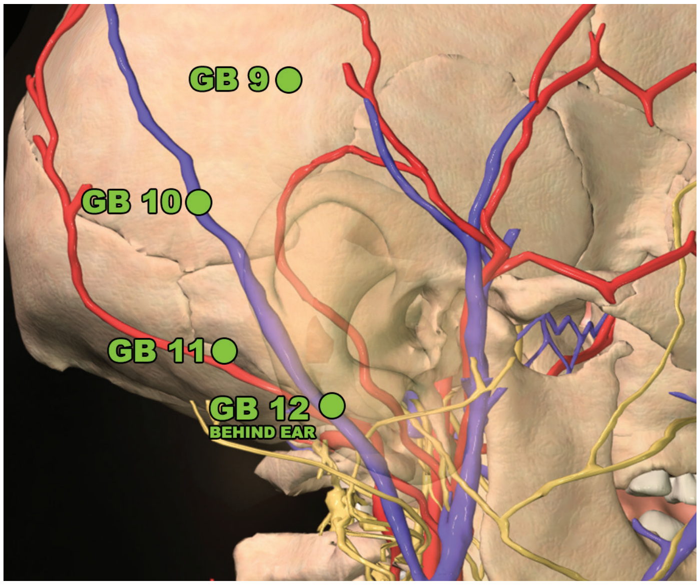

Figure 11-34. The "Yin Portals of the Head" associated with GB 11 include the acoustic auditory meatus, the nearby foramen magnum, and the jugular foramen.

- **Posterior auricular vein:** Drains the scalp posterior to the auricle. The posterior auricular vein often receives blood from the sigmoid sinus (a dural venous sinus) via the mastoid emissary vein.
- **Occipital artery (a branch of the external carotid artery):** Supplies the scalp at the back of the head.
- **Occipital vein:** Usually drains into the suboccipital venous plexus or the internal jugular vein.

Clinical Relevance: True to its name as "spasm vessel" or "tugging vessel", the posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization represents one alternative to pharmacotherapy,[14] it seems unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

of intracranial dural arteriovenous fistulae.[15] Also, blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[16] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

Indications and Potential Point Combinations

- **Headache (occipital or nuchal region):** Palpate for local trigger points, consider GB 11 if tender. Add BL 9, BL 10, GB 19, GB 21, GV 20.
- **Migraine:** GB 11, GB 20, GB 21, BL 10, GV 20, LR 3, LI 4.
- **Neck pain:** GB 11 if tender, add other trigger points, BL 10, GV 14, GB 21.
- **Ear pain:** Consider source of pain; needle trigger points referring to the ear such as GB 11 in the attachment zone of the SCM. Add input to the auriculotemporal nerve: TH 21, SI 19, GB 2, etc.
- **Sinusitis:** GB 11, BL 10, add points specific for sinus affected: BL 2, GB 14 for frontal sinus pain; LI 20, ST 3 for maxillary sinus pain.
- **Tinnitus:** Palpate for somatic dysfunction and trigger points in the temporalis, occipitalis, and suboccipital muscles. Ask the patient if pressure at any of these sites, including GB 11, reduces the intensity of the tinnitus. If so, consider a structural etiology and deactivate trigger points accordingly. Employ soft tissue therapy and myofascial release to improve fascial and structural mobility in the region, reducing pressure on the "sound system" of the ear, including the temporal bone in which it is housed.

GB 12

Wan Gu "Mastoid Process"

In a depression posterior and inferior to the mastoid process, level with the inferior ridge of the auricle. Locate by sliding a fingertip caudad from the mastoid process, into a depression.

Muscles

- **Sternocleidomastoid muscle (SCM):** Acting unilaterally, the SCM flexes the head laterally and rotates both the head and neck to cause the ear to approach the ipsilateral shoulder. Bilateral activation of the SCM causes neck flexion.
- **Splenius capitis muscle:** Extends the head and neck when both activate; working individually, the splenius rotates the head and neck toward the ipsilateral side. The splenius capitis attaches to the mastoid process at its cranial extent near GB 12.

Clinical Relevance: Myofascial dysfunction in the SCM causes pain to refer to the head and sometimes specifically the face, causing atypical facial neuralgia, tension headache, and cervicocephalalgia.

Enthesopathy of the SCM attachment at the mastoid develop secondary to central trigger points in the muscle belly. Trigger points in the sternal division of the SCM refer to the occipitotemporal and supraorbital regions, the hyoid and chin regions, cheek, TMJ, and vertex. Trigger points in the clavicular division issue referred pain patterns to the concha, posterior auricular section, and the forehead. Both divisions attach onto the mastoid process. Concomitant symptoms resulting from clavicular trigger points include disequilibrium problems such as postural dizziness or, less often, vertigo. Autonomic problems include excessive lacrimation, conjunctival hyperemia, and visual disturbances.

Trigger points in the splenius capitis (closer to BL 10) typically send pain to the vertex.

Nerves

- **Posterior auricular nerve (from the facial nerve, CN VII):** Supplies the auricularis posterior muscle and the occipital belly of the occipitofrontalis muscle.
- **Spinal accessory nerve (CN XI, motor) and branches of C2 and C3 (pain and proprioception):** Innervate the sternocleidomastoid muscle.
- **Greater occipital nerve (C2, C3):** Supplies sensation to the skin from the occiput to the vertex. The dorsal roots of C1-C3 also supply sensation to the posterior cranial fossa, along with the vagus nerve. Convergent input between the greater occipital nerve and the trigeminal nerve (which supplies the anterior and middle cranial fossa may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck.[1,2] Convergence between the cervical and trigeminal excitatory nociceptive systems argues for neuromodulatory acupuncture within the greater occipital nerve distribution for pain problems in the face, e.g., dental and sinus pain to engage inhibitory control over these neural pathways.[3]
- **Lesser occipital nerve (C2, C3):** Supplies the skin behind the ear, the superior ear, the mastoid area, and possibly a small portion of the skin of the neck. May receive communicating branches from the greater occipital nerve. The lesser and

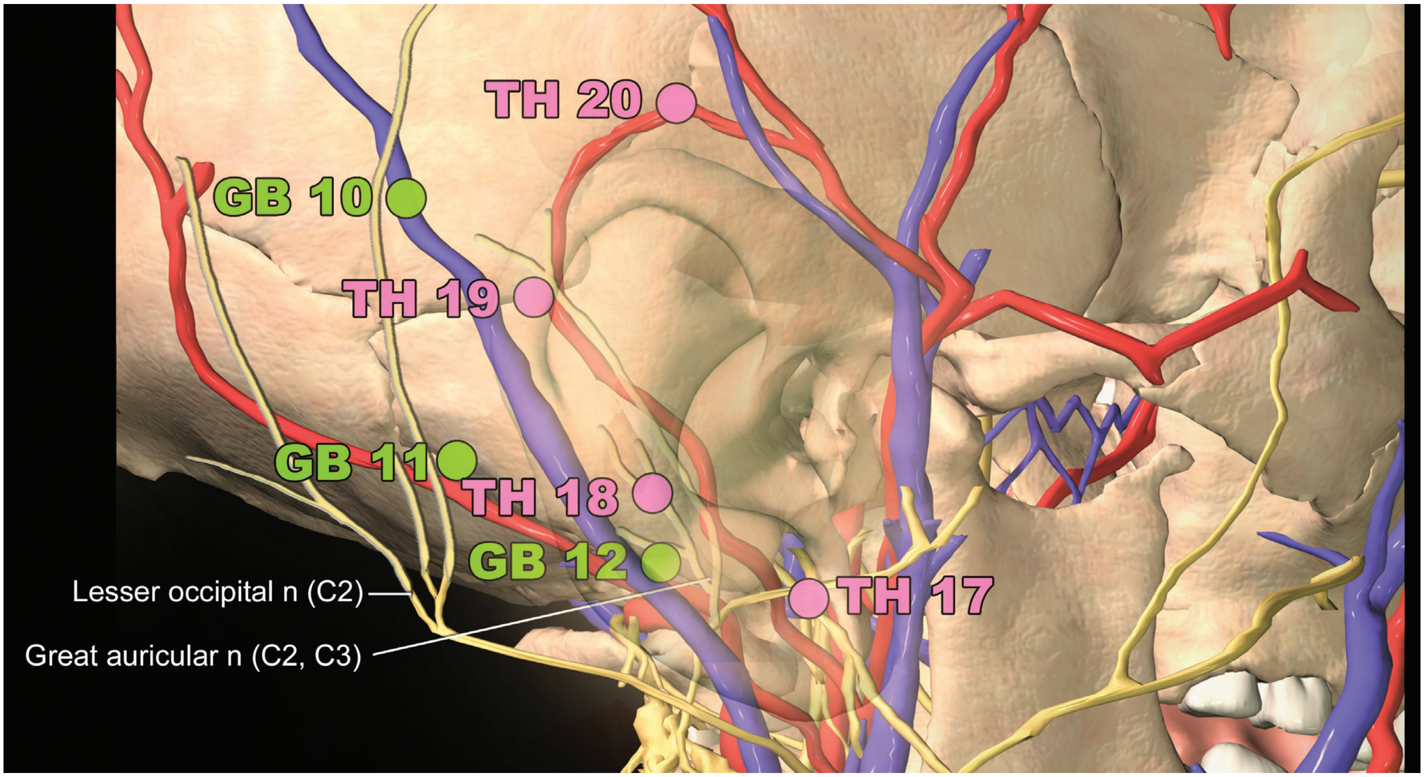

Figure 11-36. GB 12, located on the mastoid process (explaining its name), relates to both the great auricular nerve and the lesser occipital nerve, shown here. These nerves crosstalk with the vagus and facial nerves, providing for multifaceted neuromodulation. Comparative periauricular GB and TH point locations appear here as well. Not shown are the retroauricular lymph nodes that exist at this site.[22]

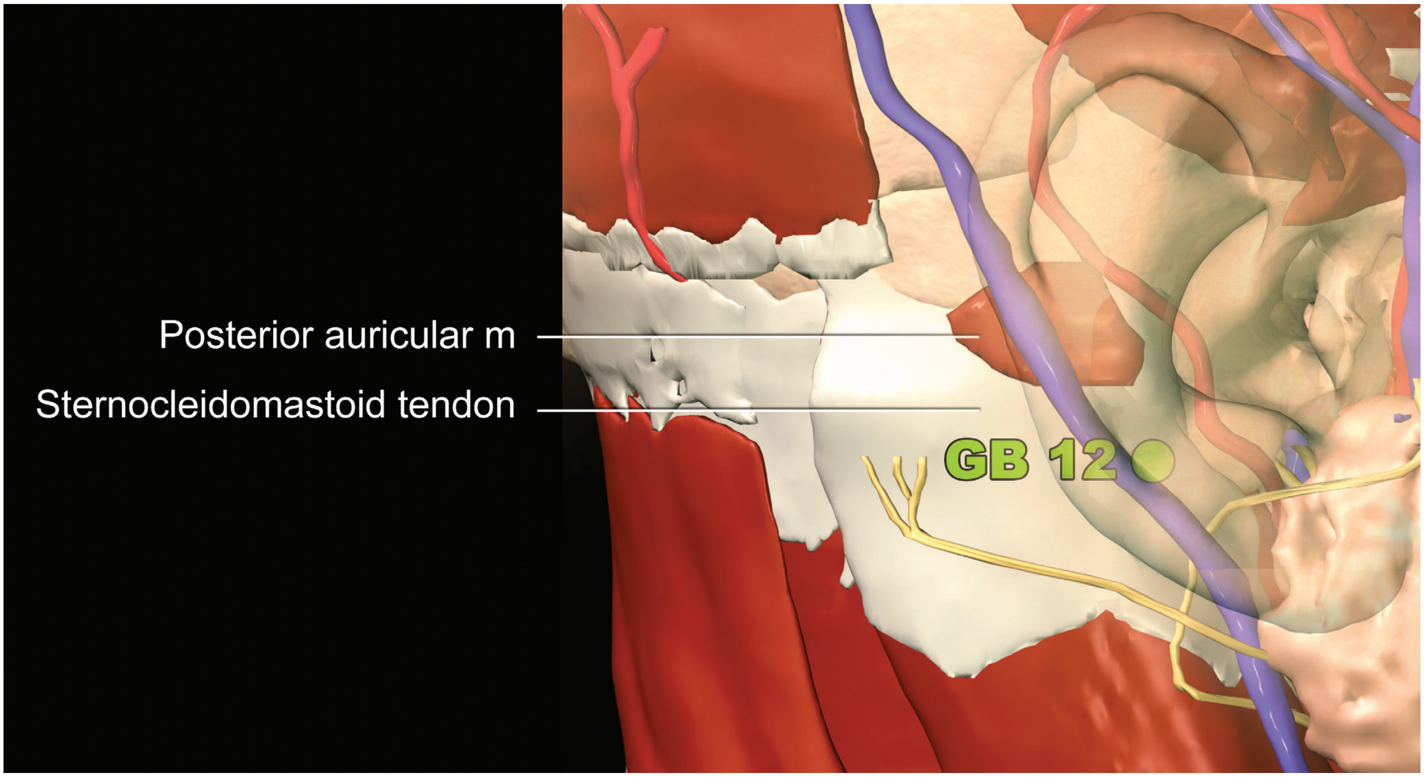

Figure 11-37. Trigger points in either the clavicular or sternal division of the SCM can produce attachment trigger points at GB 12.

greater occipital nerves pierce the trapezius at the base of the skull and are therefore subject to compression by cervical muscle tension, producing an occipital neuralgia. When this occurs, it may produce further cervical tension, perpetuating occipital head pain.

- **Greater auricular nerve (C2, C3):** Provides sensory innervation for the skin over the mastoid process, parotid gland, and pinna. Its anterior branch communicates with the facial nerve (CN VII) inside the substance of the parotid gland. The posterior branch communicates with the lesser occipital nerve, the auricular branch of the vagus, and the posterior auricular branch of the facial nerve.

Clinical Relevance: One of the risks of having a facelift performed involves nerve damage; injury to the great auricular nerve happens in about 7% of patients.[5] This nerve courses over the mid-body of the SCM where it bifurcates into anterior and posterior (or rostral and caudal) branches and its terminal arborization. Rhytidectomy surgery involving revision of cervical folds may damage the great auricular nerve and cause loss of sensation caudal to the ear. Nerve stimulation in this zone may facilitate return of sensation, depending on the type of nerve damage induced.

Extracranial nerves of the caudal portion of the head such as the posterior auricular nerve or lesser occipital undergo entrapment and compression as a result of myofascial restriction in the SCM muscle or occipitofrontalis, producing a variety of headache patterns.[6]

This region also receives sensory nerve supply from the greater occipital nerve (GON). Crosstalk between the GON and the trigeminal nerve and windup in the trigeminocervical complex in the brainstem and cervical cord supports the inclusion of GB 12 in point protocols addressing intracranial and extracranial sources of discomfort.

Stimulation of the GON can reduce pain from headaches that arise in trigeminal nerve territory, likely through mechanisms involving trigemino-cervical convergence at the level of the trigeminal nucleus caudalis.[1,7]

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[8] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[9] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[10,11]

In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[12] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[13] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[14]

Vessels

- **Posterior auricular artery:** Begins at the external carotid artery and courses posteriorly, deep to the parotid gland, and migrates along the styloid process between the ear and the mastoid process. Nourishes the scalp posterior to the auricle, as well as the auricle itself.
- **Posterior auricular vein:** Drains the scalp posterior to the auricle. The posterior auricular vein often receives blood from the sigmoid sinus (a dural venous sinus) via the mastoid emissary vein.
- **Occipital artery (a branch of the external carotid artery):** Supplies the scalp at the back of the head.
- **Occipital vein:** Usually drains into the suboccipital venous plexus or the internal jugular vein.

Clinical Relevance: True to its name as "spasm vessel" or "tugging vessel", the posterior auricular artery can cause a vascular headache, or migraine. While surgical cauterization represents one alternative to pharmacotherapy,[15] it is almost unthinkable to transect or otherwise injure a nerve when one could try neuromodulation through noninvasive means first. Furthermore, limiting blood supply to the scalp by surgically annihilating the posterior auricular artery would likely predispose the already disturbed myofascial covering to the skull to even more myofascial trigger pathology.

The posterior, or caudal, auricular artery can also be affected by vasculitides, including giant cell arteritis. When involving the posterior auricular artery, vasculitis causes pain in the auditory canal, pinna, or parotid gland.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

The occipital artery is often a main feeding artery in cases of intracranial dural arteriovenous fistulae.[16] Also, blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[17] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

Indications and Potential Point Combinations

- **Pain in mastoid region:** GB 12, GB 19.
- **Red ear syndrome (consists of red ears and burning pain triggered by tactile stimulation) involving great auricular neuropathy:**[4] Neuromodulate the great auricular nerve with GB 12,

GB 11, GB 20, TH 18, TH 19, and BL 10.

- **Tinnitus:** GB 12, SI 19, palpate for tender temporalis, trapezius, cervical paraspinal, and SCM trigger points.
- **Dysequilibirum:** GB 12, trigger points in the clavicular division of the SCM.
- **Headache:** Palpate for trigger points in the splenius capitis and SCM. Add GB 12 to address attachment trigger points at GB 12.

Evidence-Based Applications

- Nerve growth factor (NGF) injection at GB 12 and TH 17 demonstrated value for patients with **nerve deafness and tinnitus.**[18]
- Acupuncture at GB 12, BL 10, and GB 20 along with leech and centipede capsules improved blood coagulation parameters in patients with **transient cerebral ischemic attacks.**[19]
- Needling at GB 12, GB 20, and BL 10 improve blood flow through the vertebrobasilar artery. Adding GV 23 and Yintang improve emotional states and reduce tension in patients with **facial spasm, trigeminal neuralgia, and "stubborn facial paralysis".**[20]
- Acupuncture at GB 12, GB 20, TH 17, CV 23, Jinjin and YuYe alleviated **dysphagia** in patients recovering from stroke better than did routine rehabilitation alone.[21]

GB 13

Ben Shen "Root of the Spirit"

On the frontal region, 0.5 cun within the anterior hairline, on a sagittal line ascending directly upward from the lateral canthus of the eye. Located 2/3 the distance from GV 24 to ST 8.

Muscles

- **Frontal belly of the occipitofrontalis muscle:** Elevates the eyebrows and causes transverse wrinkles to appear in the forehead during frowning.

Clinical Relevance: The trigger point for the frontalis muscles sits at GB 14. It refers fingerlike projections of pain toward the hairline from the midline to the superior temporal region. The pain extends to GB 13 and GB 15 (i.e., frontalis muscle attachment trigger points) where the muscle meets the hairline at the galea aponeurotica. Tension in the frontalis muscle can entrap the supraorbital nerve, leading to a unilateral frontal headache. Frontalis trigger points worsen with anxiety and consternation, emotional states that cause tension in the forehead.

The occipitofrontalis muscle comprises two physiologically and anatomically distinct muscles.[1] The rostral limit of the galea aponeurotica in the vicinity of GB 13 and GB 15 creates a unique layering system that risks nerve entrapment. Here, the superficial fascia over the occipital belly attaches to temporoparietal fascia and the superior, or upper, border of the frontalis muscle. This superficial musculoaponeurotic complex lifts the eyebrow and pulls the scalp rostrad. In contrast, the occipital belly of the occipitofrontalis muscle joins with the galea aponeurotica and inserts on the deeper aspect, or underside, of the frontalis muscle, forming the deep musculoaponeurotic system. The occipital muscle attachment gives this layer the capacity to pull the scalp, including the superficial musculoaponeurotic system, caudad. Clinically, this layering system poses opportunities for nerve entrapment as branches travel between layers. Compression or traction of the cranial and upper cervical spinal nerves that supply the scalp, muscle, fascia, and aponeurotica leads to headache and, potentially, visual disturbances. After giving off branches that supply the upper eyelid and mucosal lining of the frontal sinus, the supraorbital nerve pierces the frontalis muscle at variable levels from the orbital rim to the mid-forehead. It also courses through the galea aponeurotica to supply sensation to the skin, subcutaneous tissue, and periosteum of the scalp as far as the vertex of the skull.[2] Palpate the rostral cranium and forehead to determine the loci of tender sites and trigger points. Treat accordingly.

Nerves

- **Supraorbital nerve (CN V_1):** Provides sensation to the forehead and scalp, as well as the frontal sinus and upper eyelid (palpebral conjunctiva). The supraorbital nerve is the largest of five branches of the ophthalmic division of the trigeminal nerve to reach the skin of the face. Innervates the mucous membrane of the frontal sinus and upper eyelid (palpebral conjunctiva); supplies skin of forehead to the hairline. The supraorbital nerve divides into deep and superficial branches. The deep branch courses between the galea aponeurotica and the periosteum.

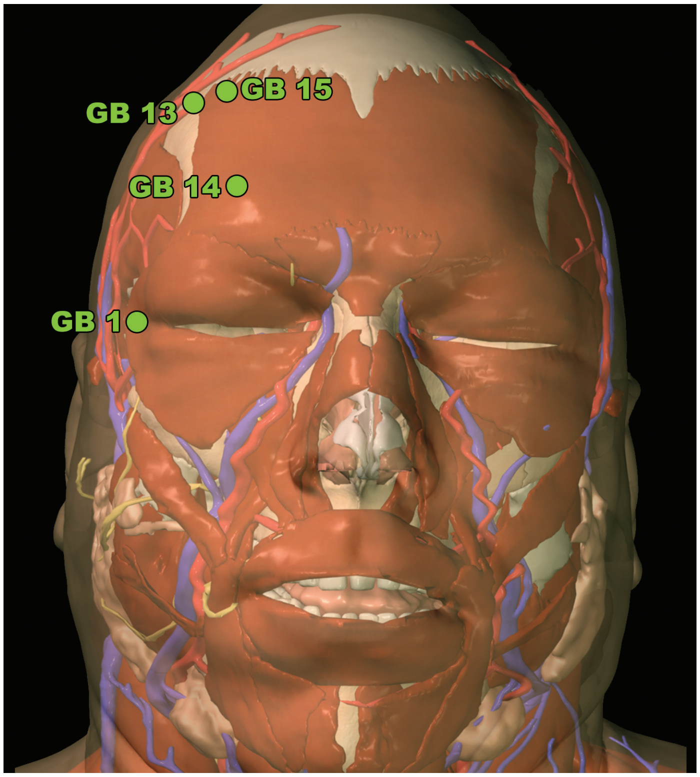

Figure 11-39. GB 13, "Root Spirit" accompanies the region shared by GB 14 and GB 15 over the frontalis portion of the epicranius, or occipitofrontalis muscle. Trigger points in the epicranius have become recognized as the generators of tension headaches that produce pain in the occiput and the forehead.

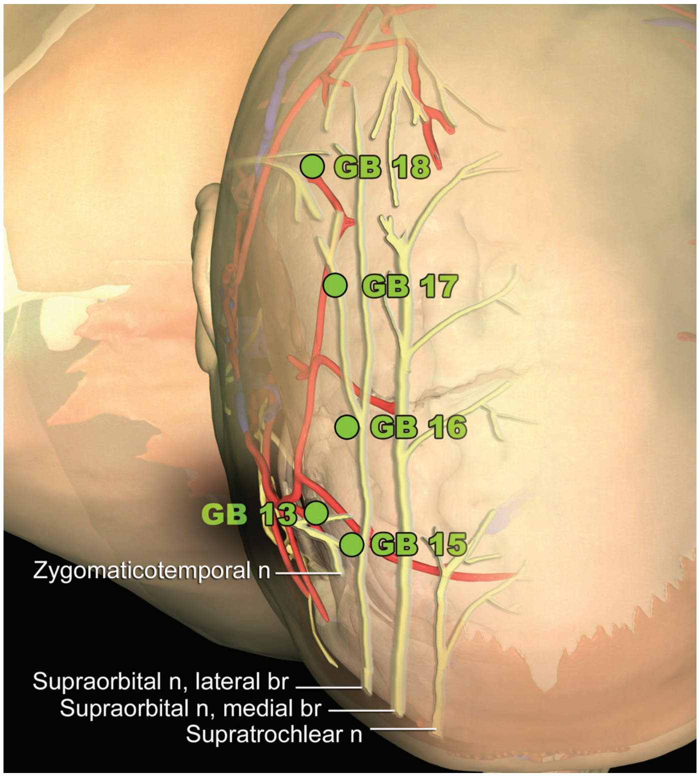

Figure 11-40. This image of the vertex (nose pointing toward the bottom of the page) investigates the neural relationships between the GB points and nerves coursing over the cranium. As shown here, GB 13 associates with the zygomaticotemporal nerve and extensions from the lateral branch of the supraorbital nerve.

The superficial branch passes through the rostral frontalis muscle and courses caudally over the muscle to supply the scalp. Branches of both the superficial and deep components of the supraorbital nerve head toward the vertex and GV 20, helping explain that point's name of "Bai Hui" or Hundred Convergences.

The lateral branch of the supraorbital nerve supplies sensation in the vicinity of GB 13 and GB 15.

- **Facial nerve (CN VII), temporal branch:** Supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior portion of the orbicularis oculi muscle. Also innervates the corrugator supercilii muscle.
- **Zygomaticotemporal nerve (CN V_2):** A sensory branch of the trigeminal nerve that courses along the lateral wall of the orbit in a groove housed in the zygomatic bone. The zygomaticotemporal nerve receives a communicating branch from the lacrimal nerve, then travels through the zygomaticotemporal foramen in the zygomatic bone. After it enters the temporal fossa, it ascend between the bone and the temporalis muscle. The nerve exits the fascia approximately one inch dorsal to the zygomatic arch. It supplies the skin of the lateral forehead with sensation. The zygomaticotemporal nerve crosstalks with the facial nerve as well as the auriculotemporal nerve (CN V_3).

Clinical Relevance: Entrapment or compression of the zygomaticotemporal branch of the trigeminal nerve can lead to frontal migraine headaches.3 Entrapment can occur due to pressure from the temporalis muscle because part of the nerve's journey takes it through the temporalis muscle or at least beneath its fascia. Treating trigger points with botulinum toxin type A injection may cause diplopia if it affects the lateral rectus muscle. Visual disturbances can last several months or more. Thus, safer means of deactivating trigger points in the zygomaticotemporal region would substitute acupuncture, laser therapy, and soft tissue manual treatment for pharmaceuticals and harsher methods.

Vessels

- **Supraorbital artery:** A terminal branch of the ophthalmic artery, which is a branch of the internal carotid artery, the supraorbital artery supplies the muscles and skin of the forehead and scalp.
- **Supraorbital vein:** Begins by anastomosing with a tributary of the superficial temporal vein, joins the supratrochlear and superior ophthalmic veins, and ends as the angular vein, at the root of the nose. It drains the forehead and anterior part of the scalp.
- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches

Figure 11-41. Anxiety produces tension in the frontalis muscle which then can cause a tension headache. GB 13's job of "rooting the spirit" as indicated by its descriptive title connotes its impact on frontal lobe activities associated with cognitive, emotional, and social functions. The frontal lobe also associates with goal-directed behavior, possibly implicated in tension headache when one confronts obstacles to achieving goals or excessive focus thereupon.

include the transverse facial, middle temporal, and anterior auricular arteries.

- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.

Clinical Relevance: The supraorbital vessels anastomose with superficial temporalis structures. Figure 11-39 reveals the proximity of the superficial temporal artery and GB 13. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and sensitizing nerves.

Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 13, considering the limited responses to conventional methods often seen.[4]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and parotid arteries.[5]

Indications and Potential Point Combinations

- **Frontal headache:** GB 13, GB 14, related trigger points. Add BL 2 for supraorbital nerve entrapment.
- **Frontal sinusitis:** GB 13, GB 14, BL 2, Yintang.

Evidence-Based Application

- Rapid needling with filiform needles at GB 13, GV 14, and LI 11 reduced fever, respiratory rate, heart rate, blood pressure, and peripheral leukocyte and lymphocyte counts in patients with **acute upper respiratory infections.**[6]

GB 14

Yang Bai "Whiteness of Yang" or "Clearing Yang"

On the frontal region, in line with the pupil when the eyes are looking straight ahead, 1 cun dorsal to the middle of the eyebrow. Located approximately at the junction of the lower and middle thirds of the distance between the eyebrow and the rostral hairline, with the distance between the glabella and the midline rostral hairline equating to 3 cun.

Muscles

- **Frontal belly of the occipitofrontalis muscle:** Elevates the eyebrows and causes transverse wrinkles to appear in the forehead during frowning.

Clinical Relevance: The trigger point for the frontalis muscles sits at GB 14. It refers fingerlike projections of pain toward the hairline from the midline to the superior temporal region. The pain extends to GB 13 and GB 15 (i.e., frontalis muscle attachment trigger points) where the muscle meets the hairline at the galea aponeurotica. Tension in the frontalis muscle can entrap the supraorbital nerve, leading to a unilateral frontal headache. Frontalis trigger points worsen with anxiety and consternation, emotional states that cause tension in the forehead. Longstanding trigger points in the clavicular division of the SCM may promote or perpetuate frontal headaches that fail to clear with deactivation of frontalis trigger points alone.

The occipitofrontalis muscle comprises two physiologically and anatomically distinct muscles.[5] The rostral limit of the galea aponeurotica in the vicinity of GB 13 and GB 15 creates a unique layering system that risks nerve entrapment. Here, the superficial fascia over the occipital belly attaches to temporoparietal fascia and the superior, or upper, border of the frontalis muscle. This superficial musculoaponeurotic complex lifts the eyebrow and pulls the scalp rostrad. In contrast, the occipital belly of the occipitofrontalis muscle joins with the galea aponeurotica and inserts on the deeper aspect, or underside, of the frontalis muscle, forming the deep musculoaponeurotic system. The occipital muscle attachment gives this layer the capacity to pull the scalp, including the superficial musculoaponeurotic system, caudad. Clinically, this layering system poses opportunities for nerve entrapment as branches travel between layers. Compression or traction of the cranial and upper cervical spinal nerves that supply the scalp, muscle, fascia, and aponeurotica leads to headache and, potentially, visual disturbances. After giving off branches that supply the upper eyelid and mucosal lining of the frontal sinus, the supraorbital nerve pierces the frontalis muscle at variable levels from the orbital rim to the mid-forehead. It also courses through the galea aponeurotica to supply sensation to the skin, subcutaneous tissue, and periosteum of the scalp as far as the vertex of the skull.[6] Palpate the rostral cranium and forehead to determine the loci of tender sites and trigger points. Treat accordingly.

Nerves

Figure 11-44. This cross section further emphasizes the relationship between GB 14 and the frontal sinus. The supraorbital nerve supplies the mucous membrane lining the frontal sinus as well as the skin on the forehead.

oculi muscle. Also innervates the corrugator supercilii muscle.

Clinical Relevance: Pain in the eye or head associated with the supraorbital nerve or, more broadly, the ophthalmic division of the trigeminal nerve, often responds to neuromodulation at this and other relevant sites. This includes not only pain in the head but also the sinuses.

Neural crosstalk between trigeminal, facial, and parasympathetic branches at and near GB 14 helps explain the point's frequent appearance in protocols for dry eye and facial nerve injury.

Vessels

- **Supraorbital artery:** A terminal branch of the ophthalmic artery, which is a branch of the internal carotid artery, the supraorbital artery supplies the muscles and skin of the forehead and scalp.
- **Supraorbital vein:** Begins by anastomosing with a tributary of the superficial temporal vein, joins the supratrochlear and superior ophthalmic veins, and ends as the angular vein, at the root of the nose. It drains the forehead and anterior part of the scalp.

Clinical Relevance: The supraorbital vessels anastomose with their superficial temporal neighbors. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and sensitizing nerves.

Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 14, considering the limited responses to conventional methods often seen.[7]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and parotid arteries.[8]

Indications and Potential Point Combinations

- **Frontal headache:** GB 14, attachment trigger points of the frontalis muscle (such as GB 13 and GB 15), Yintang, BL 10, GB 20.
- **Frontal sinusitis:** GB 14, Yintang, BL 2.
- **Eye problems:** pain, discharge, night blindness, epiphora, blepharospasm: GB 14, BL 2, GB 1, Yintang, TH 23.
- **Migraine (frontal):** TH 23, GB 14, BL 2, LI 4, LR 3, GV 20, and pertinent trigger points.

Evidence-Based Applications

- A randomized, placebo-controlled trial suggested that treatment with laser acupuncture at LU 7, LI 4, GB 14, and GB 20 benefits **chronic tension headache.**[1]

- Acupuncture at LR 3, SP 6, ST 36, CV 12, LI 4, PC 6, GB 20, GB 14, Taiyang, and GV 20 provided greater effectiveness in **prophylaxis of migraine** compared to flunarizine.[2]
- Case series reported electroacupuncture at GB 14, GB 20, SI 18, ST 7, and LI 4 was effective treatment for **peripheral facial paralysis.**[3]
- Needling at GB 14, BL 2, ST 3, Shangneidicang, Xiangneidicang, LI 20, SI 18, and ST 36, along with direct moxibustion at GB 14 and ST 4 (2cm-3cm above the skin for 5 minutes) rapidly improved signs of **Bell's palsy** in a 27-week pregnant patient.[9]
- Evidence based points for **peripheral facial nerve paralysis** include: GB 14, GB 20, ST 2, ST 4, ST 6, ST 7, CV 24, LI 20, SI 18, TH 17, GV 26, Yuyao, and LI 4. Treatments should take place daily for intervals of 10 visits with 2-5 days off between intervals, for 20-40 total treatments.[10]
- Thermography of the face in patients with **peripheral facial nerve paralysis** may aid in indicating ideal points to treat based on temperature at the points. Most frequent points selected based on temperature included, in decreasing order, ST 4, LI 20, Taiyang, GB 14, and SI 18.[11]
- Acupuncture at ST 2, ST 8, ST 36, GB 1, GB 14, BL 2, and LI 4 provided subjective beneficial effects in patients with keratoconjunctivitis sicca **(KCS or dry eye).**[4]
- Treatment with acupuncture at TH 23, GB 14, BL 2, Taiyang, ST 1, GB 20, LI 4, LI 11, and GV 23 improved patients' ocular surface disease index (OSDI), lessened pain, and increased tear film break up time significantly after eight weeks of treatment for patients with **dry eye.**[12]
- Acupuncture at GB 14, GB 20, BL 2, TH 23, Ex 1, ST 1, and GV 23 along with SP 3, LU 9, LU 10, and HT 8 produced improvements in signs and symptoms of **dry eye** both with and without de qi manipulation and with both superficial and deep needling.[13]

GB 15

Tou Lin Qi "Head Overlooking Tears", "Tears Control"

On the frontal region, directly in line with the pupil and GB 14, 0.5 cun within the rostral hairline. Approximately 3 cun lateral to the midline and midway between GV 24 and ST 8. If the rostral hairline is not evident, find its likely location by finding one-fifth the distance from the glabella (or Yintang, GV 24.5) and the caudal hairline. Because the distance between the glabella and the caudal hairline equals 15 cun, one-fifth the distance equals 3 cun, which is where the rostral hairline should fall. If the location of the caudal hairline is indistinct, it can be assumed to be located 1 cun caudal to GV16, immediately below the external occipital protuberance.

Figure 11-41 reveals the comparative locations of GB 13, GB 15, BL 4, BL 3, and GV 24, which line up from the temporal region to the midline along the same horizontal plane.

Connective Tissues

- **Galea aponeurotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Appears in Figure 7-13, labeled at the bottom right area of the image.

Clinical Relevance: Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as BL 6, as well as deactivating trigger points in the frontalis (e.g., GB 14, GB 15) and the occipitalis (e.g., BL 9) muscles.

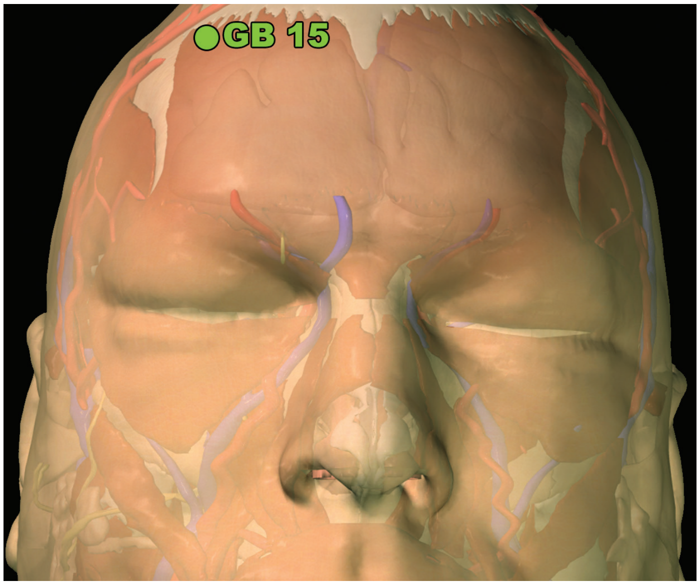

Figure 11-45. As a local point, GB 15 treats pain in the forehead from myofascial dysfunction and/or supraorbital nerve irritation. The supraorbital nerve may become neuropathic due to sinusitis, ongoing eye pain, or nerve entrapment by the frontalis. The name "Head Overlooking Tears" refers to the point's location directly in line with the pupil. It further suggests the ability of the trigeminal nerve to reflexively stimulate tear production. Insofar as the name "Tears Control", trying to hold back tears would cause frontalis muscle contraction. This image exposes the relationship of the frontal sinuses to GB 15, as seen thru semi-translucent muscle and skin layers.

Muscles

- **Frontal belly of the occipitofrontalis muscle:** Elevates the eyebrows and causes transverse wrinkles to appear in the forehead during frowning.

The trigger point for the frontalis muscles sits at GB 14. It refers fingerlike projections of pain toward the hairline from the midline to the superior temporal region. The pain extends to GB 13 and GB 15 (i.e., frontalis muscle attachment trigger points) where the muscle meets the hairline at the galea aponeurotica.

Tension in the frontalis muscle can entrap the supraorbital nerve, leading to a unilateral frontal headache. Frontalis trigger points worsen with anxiety and consternation, emotional states that cause tension in the forehead.

Nerves

- **Supraorbital nerve (CN V_1):** Provides sensation to the forehead and scalp, as well as the frontal sinus and upper eyelid (palpebral conjunctiva). The supraorbital nerve joins with the supratrochlear nerve to form the frontal nerve. As the frontal nerve enters the superior part of the orbit, a small sensory twig from the frontal sinus latches on. By the time the frontal nerve reaches and enters the superior orbital fissure, the lacrimal and nasociliary nerves have banded together with the frontal nerve, coalescing into the ophthalmic division of the trigeminal nerve.
- **Facial nerve (CN VII), temporal branch:** Supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior portion of the orbicularis oculi muscle.

Clinical Relevance: Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel) to the vertex.[1] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes. However, differential diagnoses for SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, or other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (the supraorbital notch). Dry needling of GB 15, BL 2, BL 6, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

Vessels

- **Supraorbital artery:** A terminal branch of the ophthalmic artery, which is a branch of the internal carotid artery, the supraorbital artery supplies the muscles and skin of the forehead and scalp.
- **Supraorbital vein:** Begins by anastomosing with a tributary

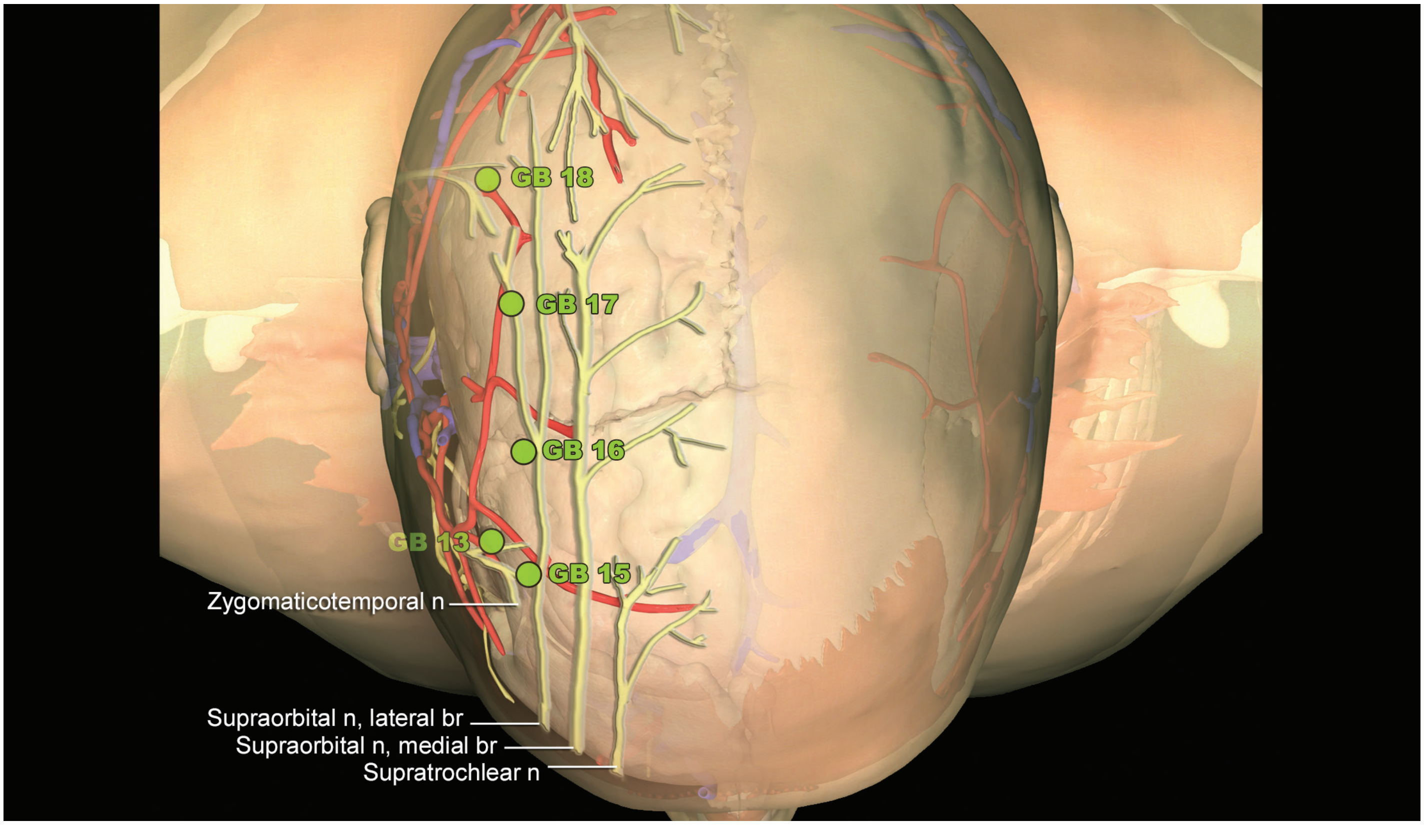

Figure 11-46. GB 15 marks the beginning of the GB line's journey across the skull in conjunction with the supraorbital nerve, a branch of the trigeminal nerve. The trigeminal nerve also supplies the meninges of the rostral and middle cranial fossae. Cutaneous, musculoskeletal, visceral, and dural afferents, converge onto nociceptive neurons in the dorsal horn of the first cervical spinal segment. This helps explain the precipitation of migraine and other types of headache from musculoskeletal dysfunction, visceral upset, and dural irritation. It also provides a mechanism through which to understand how neuromodulation by means of acupuncture benefits migraineurs.

of the superficial temporal vein, joins the supratrochlear and superior ophthalmic veins, and ends as the angular vein, at the root of the nose. It drains the forehead and anterior part of the scalp.

- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.
- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.

Clinical Relevance: The supraorbital vessels anastomose with superficial temporalis structures. Figure 11-46 reveals the proximity of the superficial temporal artery and GB 15. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and sensitizing nerves.

Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 15, considering the limited responses to conventional methods often seen.[2]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and carotid arteries.[3]

Indications and Potential Point Combinations

- **Frontal headache:** Address trigger points in the frontalis portion of the epicranius (occipitofrontalis) muscle, including GB 15 and GB 13 as attachment trigger points (ATrP's) and GB 14 as the central trigger point.
- **Migraine:** GB 15 if tender, other trigger points on the head and neck as found, LI 4, LR 3, ST 36, GV 20, BL 10.
- **Eye problems:** Excessive tearing in the wind, eye pain, especially in the lateral canthus: GB 15, GB 1, TH 23, GV 20.
- **Rhinitis:** GB 15, Yintang, LI 20.
- **Seizures:** GB 15, ST 36, LR 3, LI 4, BL7, BL 8, GV 20.

GB 16

Mu Chuang "Window of the Eye", "Eye Window"

On the frontal region, 1.5 cun caudal to GB 15 on a line connecting GB 15 and GB 20, 2.25 cun lateral to the midline. After locating GB 15 0.5 cun caudal to the rostral hairline, locate GV 20. Next, find GB 18 directly lateral to GV 20, on the GB channel you described by connecting GB 15 and GB 20. Find GB 16 one-third the distance from GB 15 to GB 18.

Connective Tissues

- **Galea aponeurotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Appears in Figure 11-48.

Clinical Relevance: Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as BL 6, as well as deactivating trigger points in the frontalis (e.g., GB 14, GB 15), the occipitalis (e.g., BL 9) muscles, and the border of the aponeurotica (e.g., GB 16, GB 17, and GB 18).

Nerves

- **Supraorbital nerve (CN V_1):** Provides sensation to the forehead and scalp, as well as the frontal sinus and upper eyelid (palpebral conjunctiva). The supraorbital nerve joins with the supratrochlear nerve to form the frontal nerve. As the frontal nerve enters the superior part of the orbit, a small sensory twig from the frontal sinus latches on. By the time the frontal nerve reaches and enters the superior orbital fissure, the lacrimal and nasociliary nerves have banded together with the frontal nerve, coalescing into the ophthalmic division of the trigeminal nerve.

Clinical Relevance: Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel) to the vertex.[1] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes. However, differential diagnoses for SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, or other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (the supraorbital notch). Dry needling of GB 16, GB 15, BL 6, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

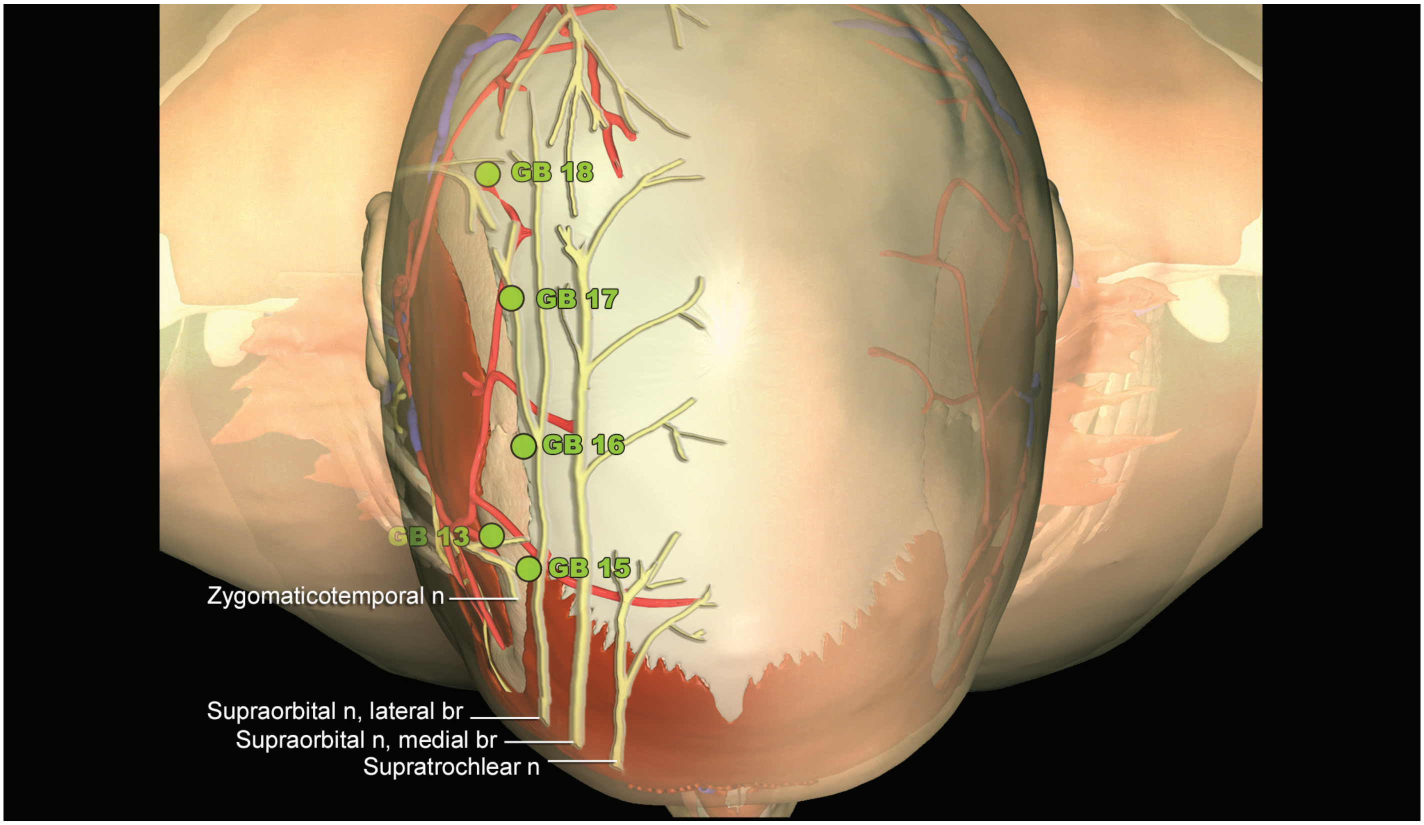

Figure 11-47. GB 16 relates to the supraorbital nerve and thus has indirect effects on eye pain, providing a neuroanatomic basis for its descriptive name of "Eye Window". Some patients develop a palpable groove over the coronal suture near GB 16. This "post-coronal sulcus" appears to form due to the persistence of a transverse band of epicranial aponeurosis.[4] Thus, the GB line follows both the lateral branch of the supraorbital nerve as well as the aponeurotic border. Both anatomical features may account for tenderness to palpation.

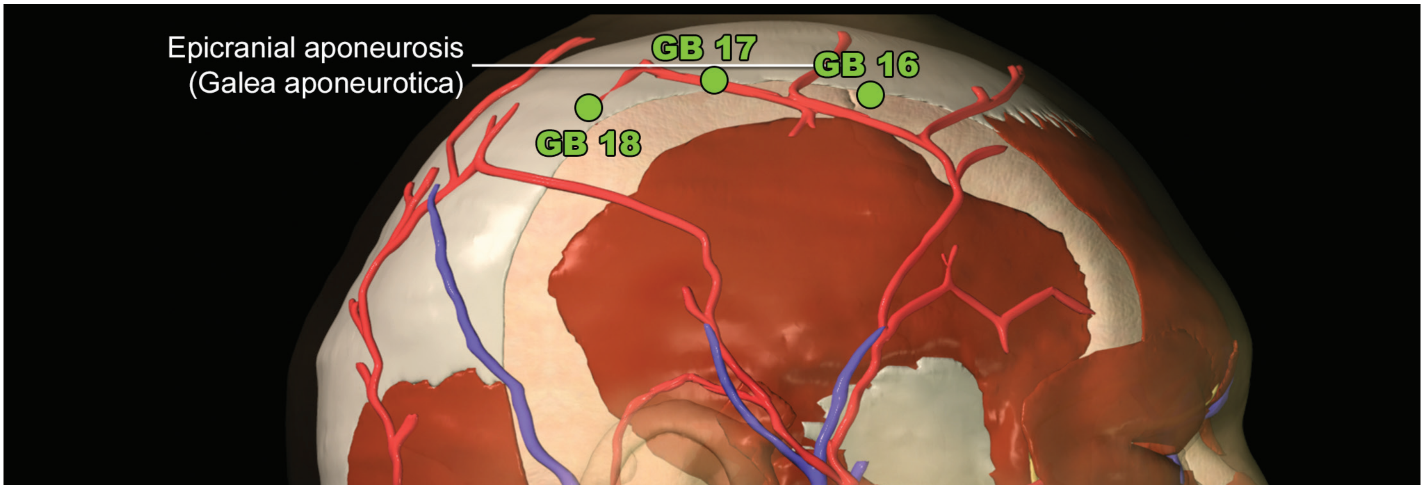

Figure 11-48. This soft tissue view depicts the location of GB 16, GB 17, and GB 18 along the lateral border of the epicranial aponeurosis. These points may or may not fall along the border in each individual. Decide on their inclusion and location based on palpation.

Vessels

- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.
- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle. Joins the maxillary vein to form the retromandibular vein.

Clinical Relevance: Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and sensitizing nerves.

Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 16, considering the limited responses to conventional methods often seen.[2]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and carotid arteries.[3]

Indications and Potential Point Combinations

- **Tension headache:** Palpate for trigger points in the epicranius muscle as well as along the galea aponeurotica border, at GB 16, GB 17, and GB 18. Add GB 20 and GB 21 if trigger points occur in those regions.
- **Eye pain:** GB 16, GB 14, BL 2, TH 23, GB 20, LR 3.
- **Jetlag:** GB 16, GV 20, Yintang.

Zheng Ying "Upright Nutrition", "Upright Construction", "Right Meeting"

On the parietal region, 1.5 cun caudal to GB16, on the line connecting GB 15 and GB 20, 2.25 cun lateral to the midline. After locating GB 15, 0.5 cun caudal to the rostral hairline, find GV 20. Next, locate GB18 directly lateral to GV 20, on the GB channel you delineated by connecting GB 15 to GB 20. Now, find GB 16 two-thirds the distance from GB 15 to GB 18.

Connective Tissues

- **Galea aponeurotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Appears in Figure 11-49A.

Clinical Relevance: Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as BL 6, as well as deactivating trigger points in the frontalis (e.g., GB 14, GB 15), the occipitalis (e.g., BL 9) muscles, and the border of the aponeurotica (e.g., GB 16, GB 17, and GB 18).

Nerves

- **Supraorbital nerve (CN V_1):** Provides sensation to the forehead and scalp as well as the frontal sinus and upper eyelid (palpebral conjunctiva). The supraorbital nerve joins with the supratrochlear nerve to form the frontal nerve. As the frontal nerve enters the superior part of the orbit, a small sensory twig from the frontal sinus latches on. By the time the frontal nerve reaches and enters the superior orbital fissure, the lacrimal and nasociliary nerves have banded together with the frontal nerve, coalescing into the ophthalmic division of the trigeminal nerve.

Clinical Relevance: Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve, which follows the BL and GB channels with its medial and lateral branches, respectively, to the vertex.[1] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes. However, differential diagnoses for SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, or other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (the supraorbital notch). Dry needling of GB 17, GB 15, BL 6, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

Vessels

- **Superficial temporal artery:** Supplies the skin over the frontal and temporal regions along muscles of the face. Arises from the external carotid artery, posterior to the neck of the mandible. Divides into frontal and parietal branches. Other branches include the transverse facial, middle temporal, and anterior auricular arteries.
- **Superficial temporal vein:** Drains the side of the scalp, the external ear, and the superficial levels of the temporal muscle.

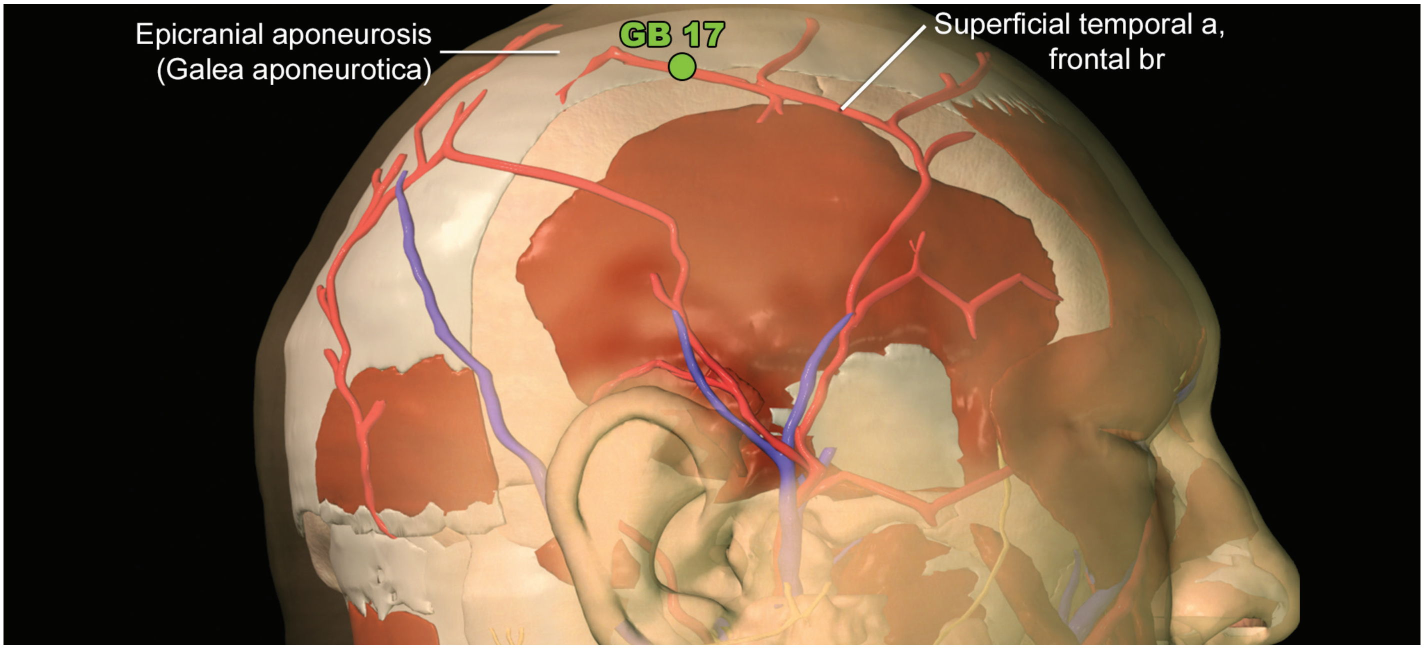

Figure 11-49A. The various names forx GB 17, including "Upright Construction", "Right Meeting", and "Upright Nutrition" indicate the intersection of the superficial temporal artery, the supraorbital nerve (not shown in this image), and the border of the galea aponeurotica.

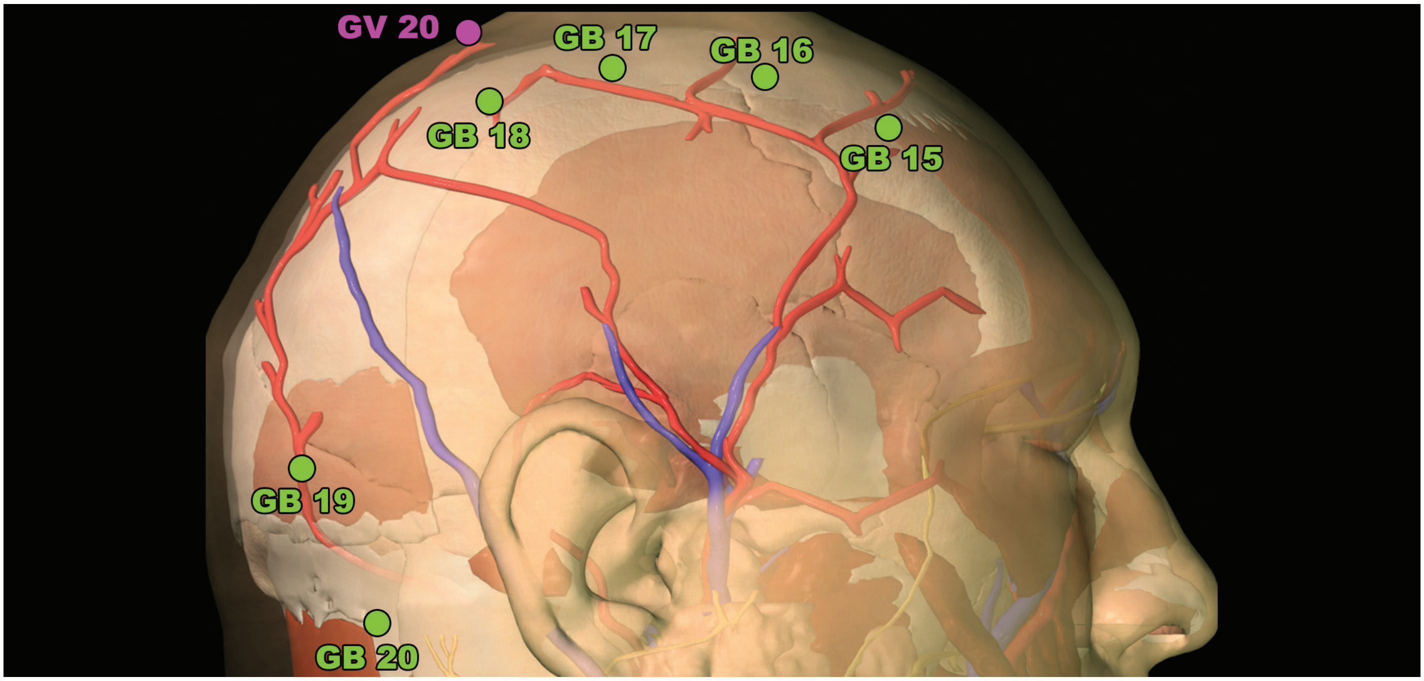

Figure 11-49B. Finding GB 17 and GB 16 utilizes proportional measurements. That is, one first draws the GB line by connecting GB 15 to GB 20. Then, one locates GB 18 lateral to GV 20. GB 17 and GB 16 land at equidistant thirds along a line connecting GB 18 to GB 15. This image also outlines the proximity of GB 15 through GB 18 to the temporal line of the skull, denoting the perimeter of the temporal fossa. This region can become tender to palpation in individuals with chronic headaches and TMJ dysfunction.

Joins the maxillary vein to form the retromandibular vein.

- **Occipital artery:** Arises from the external carotid artery and accompanies the occipital nerve in the occipital region. Its distribution includes the scalp at the back of the head.
- **Occipital vein:** Drains the occipital region of the scalp.

Clinical Relevance: Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and sensitizing nerves.

Acupuncture and related techniques should be attempted prior to surgical or other invasive maneuvers for non-atherosclerotic vascular disease, including conditions affecting extracranial vessels such as those located near GB 17, considering the limited responses to conventional methods often seen.[2]

The vasa nervorum of the peripheral facial nerve arise from a network of vessels formed mainly by the superficial temporal, facial, transverse facial, and zygomatico-orbital arteries. These small vessels also derive from collateral branches of the supraorbital, deep temporal, buccal and carotid arteries.[3]

The occipital artery is often a main feeding artery in cases of intracranial dural arteriovenous fistulae.[4] Blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[5] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

Indications and Potential Point Combinations

- **Local head pain:** GB 17 plus other local trigger points. Add GB 19 and GB 14 to relax the occipitofrontalis muscle.

On the parietal region, 1.5 cun behind GB 17 and 2.25 cun lateral to GV 20, on the line connecting GV 20 and the apex of the ear.

Connective Tissues

- **Galea aponeurotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Appears in Figure 11-49A.

Clinical Relevance: Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as BL 6, as well as deactivating trigger points in the frontalis (e.g., GB 14, GB 15), the occipitalis (e.g., BL 9) muscles, and the border of the aponeurotica (e.g., GB 16, GB 17, and GB 18).

From a trigger point perspective, although muscles are largely absent from the vertex region, dysfunction in the sternocleidomastoid (sternal head) and the splenius capitis sometimes refer pain to the top of the head. As such, patients presenting with vertex pain may be harboring trigger points in the cervical musculature, calling for palpation of the entire head and neck region.

Nerves

- **Supraorbital nerve (CN V_1):** Provides sensation to the forehead and scalp, as well as the frontal sinus and upper eyelid (palpebral conjunctiva).
- **Greater occipital nerve (C2, C3):** Supplies sensation to the skin from the occiput to the vertex. The dorsal roots of C1-C3 also supply sensation to the posterior cranial fossa, along with the vagus nerve. Convergent input between the greater occipital nerve and the trigeminal nerve (which supplies the anterior and middle cranial fossa may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck.[1,2]
- **Lesser occipital nerve (C2, C3):** Supplies the skin behind the ear, the superior ear, the mastoid area, and possibly a small portion of the skin of the neck. May receive communicating branches from the greater occipital nerve. The lesser and greater occipital nerves pierce the trapezius at the base of the skull and are therefore subject to compression by cervical muscle tension, producing an occipital neuralgia. When this occurs, it may produce further cervical tension, perpetuating occipital head pain.

Clinical Relevance: Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve, which follows the BL and GB channels with its medial and lateral branches, respectively, to the vertex.[3] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes. However, differential diagnoses for SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, or other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (the supraorbital notch). Dry needling of GB 18, GB 17, GB 15, BL 6, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

GB 18 receives innervation from the greater occipital nerve, as shown in Figure 11-52. Thus, a compressed or otherwise irritated greater occipital nerve secondary to cervical spinal arthritis or head trauma could derive benefit from neuromodulation through acupuncture and related techniques at this site. The greater occipital nerve has been identified as a contributor to several types of headaches, including cluster, cervicogenic, migraine, medication-overuse, tension, and hemicrania continua.[4]

Functional connectivity between trigeminal and cervical afferents exists in the brain stem where afferent fibers from the three most cranial cervical spinal nerve roots converge onto neurons in the spinal nucleus of the trigeminal nerve.[5] This explains the widespread sensory, motor, and autonomic phenomena that arise in various headache states, including migraine and occipital neuralgia.

At GB 18, the innervation of the GB line shifts from predominantly

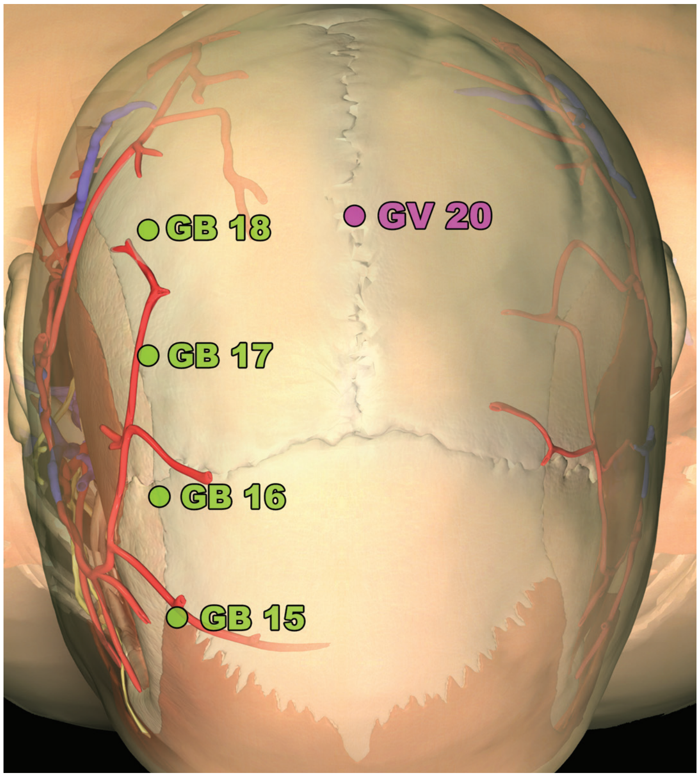

Figure 11-51. GB 18, "Spirit Support", lands lateral to GV 20 and the vertex of the skull, regarded as a central locus of mental processes, as they relate to mind and spirit.ce

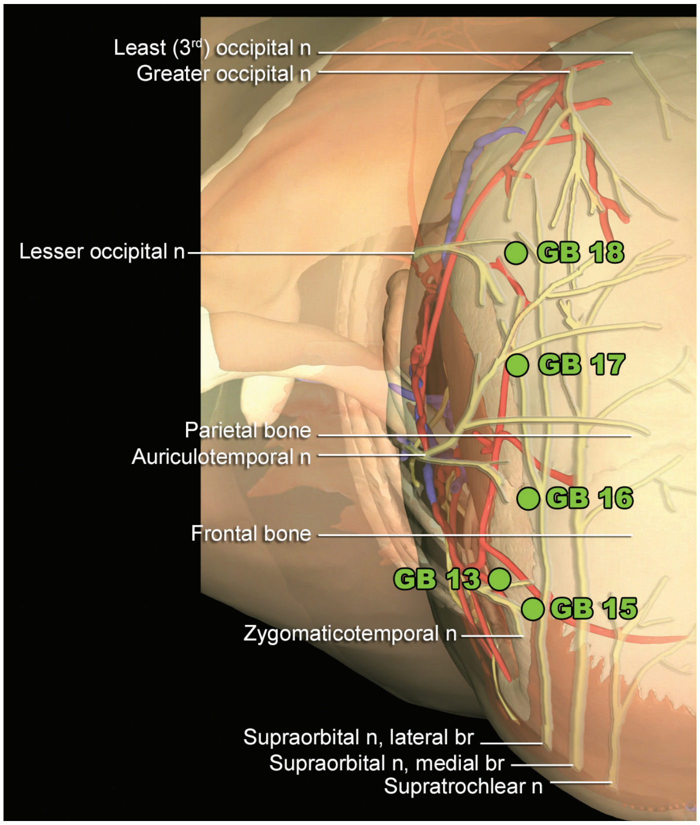

Figure 11-52. GB 18 overlies the parietal bone, which in Chinese means "Heaven Support", further accounting for its name.[17] GB 18, and to some extent GB 17, occupy a region near the vertex that receives convergent sensory input from both trigeminal and cervical nerve sources; these two sensory pathways then crosstalk with the vagal centers, providing autonomic neuromodulation.

trigeminal nerve-based (GB 13 to GB 17) to a much larger greater occipital nerve influence (GB 18 - GB 19). Thus, these points may better address cervicogenic headaches than those arising from trigeminal nerve irritation. That said, however, if one considers the convergence of upper cervical spinal nerve afferents onto the spinal nucleus of the trigeminal nerve, an anatomical basis manifests for crosstalk occurring between nerves supplying both the rostral and caudal cranium.[6] Furthermore, tension in the occipitofrontalis muscle worsens nerve irritation; relaxing both the occipitalis and frontalis with dry needling suggests treatment of rostral and caudal GB (and/or BL) loci.

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[7] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[8] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[9,10]

As a differential diagnosis for migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[11] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[12] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[13]

Functional brain imaging reveals how neuromodulation affects cerebral activation levels, whether the stimulation arrives by cranial, spinal, or peripheral neural avenues. Functional magnetic resonance imaging (fMRI) research evaluating the effects of acupuncture on the brain has compared stimulation of scalp and body loci. Findings expose unique signal activations between the two groups, most likely resulting from the different afferent endings stimulated by each approach.[14] The scalp acupuncture group (needled at left-side only TH 20, GB 18, GB 9, and Sishencong) demonstrated more activity in the contralateral somatosensory association cortex, the postcentral gyrus, and the parietal lobe as compared to the limb acupuncture group, who received treatment at right-side only LI 1, LI 10, LR 3, and ST 36. Perhaps unsurprisingly, the latter points produced activation in the right occipital lobe, lingual gyrus, visual association cortex, right parahippocampal gyrus, limbic lobe, hippocampus, left anterior lobe, culmen, and cerebellum.

Vessels

- **Occipital artery:** Arises from the external carotid artery and accompanies the occipital nerve in the occipital region. Its distribution includes the scalp at the back of the head.
- **Occipital vein:** Drains the occipital region of the scalp.

Clinical Relevance: Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and sensitizing nerves.

The occipital artery is often a main feeding artery in cases of intracranial dural arteriovenous fistulae.[15] Blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[16] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

Indications and Potential Point Combinations

- **Headache:** Check for trigger points in the occipitofrontalis, temporalis, and trapezius muscles. Add GB 18 for tenderness to palpation along the epicranial aponeurosis.
- **Fever:** GB 18, GV 20, LI 4.
- **Rhinitis:** GB 18, GV 20, Yintang, BL 10.
- **Epistaxis:** GB 18, GV 20.

GB 19

Nao Kong "Brain Hollow"

On the occipital region, 2.25 cun lateral to the midline, level with the upper border of the external occipital protuberance (i.e., level with GV 17). Directly above GB 20. First locate GV 17, which is 1.5 cun directly above GV16, in the depression superior to the external occipital protuberance. If the external occipital protuberance is difficult to find, locate GB 19 one-fourth the distance from GB 20 to GB 18. Figure 11-53 illustrates the relationship of GB 19 to GV 17 and GB 18.

Muscles

- **Occipital belly of the occipitofrontalis muscle:** Moves the scalp backward by drawing back the galea aponeurotica. The occipital belly becomes active during smiling and yawning. Ear movements can also activate the occipital belly.[4]

Clinical Relevance: Myofascial trigger point pathology at GB 19 in the occipitalis muscle radiates pain strongly toward GB 18, GB 17, and GB 16. The referred pain pattern actually extends the entire GB trajectory over the skull to GB 13 and GB 15. It then hops to the upper lid and GB 1. This trigger point pain pattern explains at least in part how a headache caused by myofascial restriction at the back of the head causes one to feel pain in the eye.

Nerves

- **Greater occipital nerve (GON) (C2, C3):** Supplies sensation to the skin from the occiput to the vertex. The dorsal roots of C1-C3 also supply sensation to the posterior cranial fossa, along with the vagus nerve. Convergent input between the greater occipital nerve and the trigeminal nerve (which supplies the anterior and middle cranial fossa may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck.[1,2]
- **Posterior auricular nerve (CN VII):** Innervates the occipital belly of the occipitofrontalis (or epicranius) muscle.

Clinical Relevance: The GON arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[5] (The occipital artery appears in Figure 11-53 deep to GB 19.) As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.

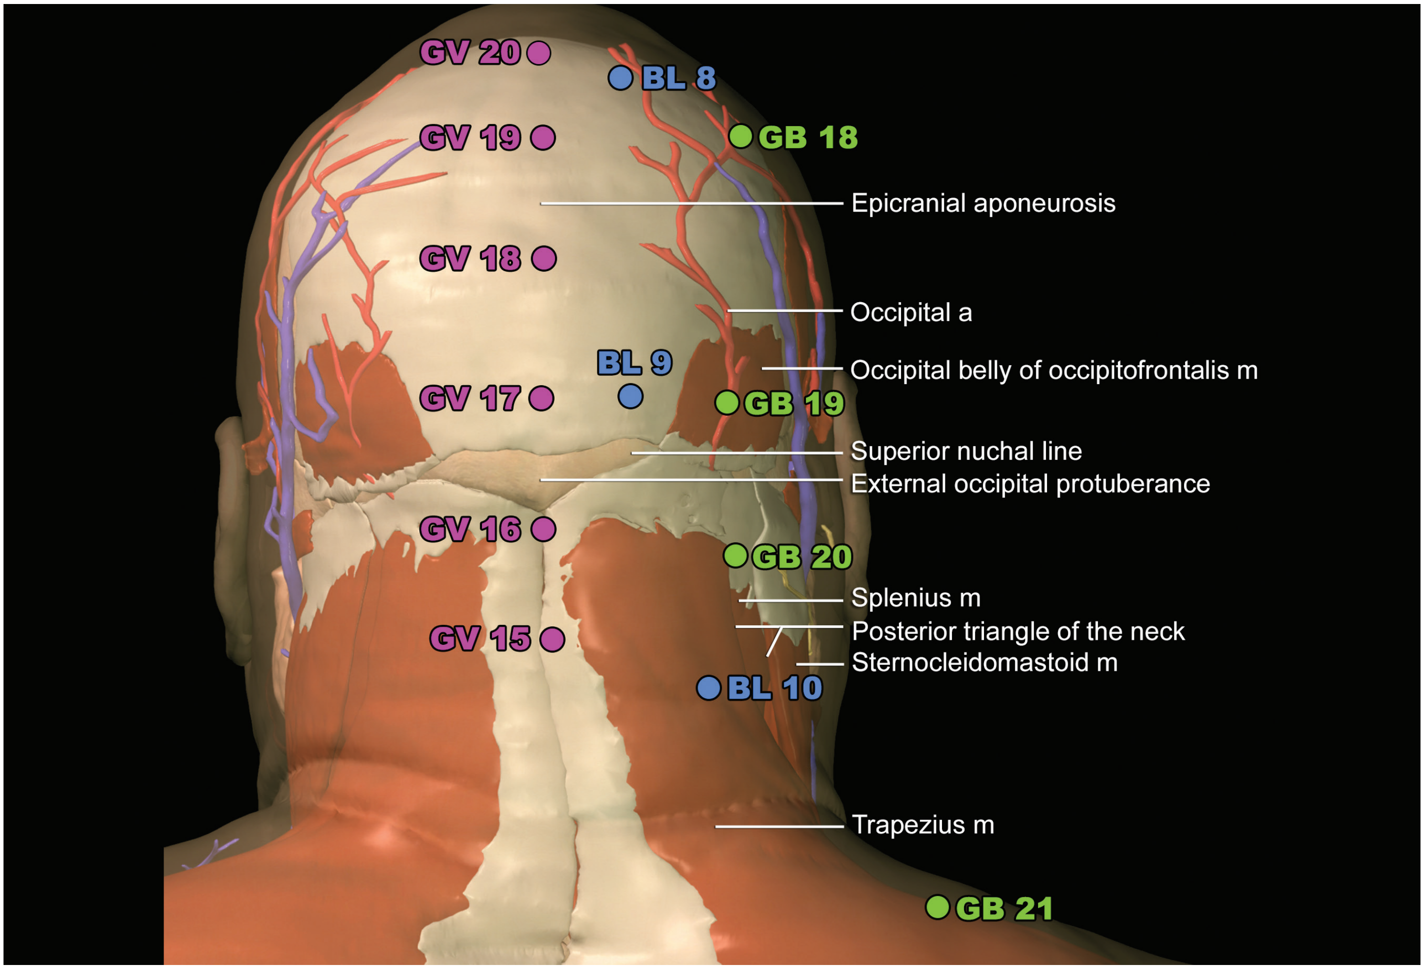

Figure 11-53. The trigger point within the occipitalis portion of the epicranius muscle lands at GB 19. It produces a referred pain pattern that arches over the skull along the GB line toward the eye between the brow and the upper lid. Patients suffering from the pain of a GB 19 trigger point may complain that they cannot bear the weight of the back of the head on a pillow at night because the pressure activates the pain.

GB 19 receives sensory nerve supply from the greater occipital nerve (GON). Crosstalk between the GON and the trigeminal nerve and windup in the trigeminocervical complex in the brainstem and cervical cord supports the inclusion of GB 19 in point protocols addressing intracranial and extracranial sources of discomfort.

Stimulation of the GON can reduce pain from headaches that arise in trigeminal nerve territory, likely through mechanisms involving trigemino-cervical convergence at the level of the trigeminal nucleus caudalis.[6]

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[7] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[8] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[9,10]

In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[11] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[12] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[13]

Extracranial nerves of the caudal portion of the head such as the posterior auricular nerve or lesser occipital undergo entrapment and compression as a result of myofascial restriction in the SCM muscle or occipitofrontalis, producing a variety of headache patterns.[14]

bution includes the scalp at the back of the head.

- **Occipital vein:** Drains the occipital region of the scalp.

Clinical Relevance: The occipital artery is often a main feeding artery in cases of intracranial dural arteriovenous fistulae.[15] Also, blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[16] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites. The spatial relationships between GB 19, the posterior auricular vein, the mastoid bone, and the sigmoid sinus appear clearly in Figure 11-54.

Indications and Potential Point Combinations

- **Headache in patients with eye disorders such as decreased visual acuity or glaucoma, causing chronic activation of the epicranius muscle:** GB 19, GB 14, Yintang, select trigger points on the face, scalp, and neck that contribute to the head pain. Also, check the posterior digastrics and semispinalis cervicis for trigger point tenderness and stimulation of the pain pattern the patient recognizes. Consider occipital neuralgia as a concomitant pain-producing problem. Add BL 10, BL 9, and GV 29.

Evidence-Based Applications

- Case series illustrates application of GB 19 for **dizziness/ vertigo, infantile convulsion, senile dementia, and urinary incontinence.**[3]

GB 20

Feng Chi "Wind Pool"

On the junction of occipital and nuchal regions, in the hollow between the origins of the trapezius and sternocleidomastoid muscles, approximately at the level of the lower margin of the external occipital protuberance, level with GV 16. Approximately midway between GV 16 and GB 12.

Caution: Some ancient texts advise angling the needle in the direction of the contralateral globe. Some have recommended aiming toward the apex of the nose.[1] While this may reduce the likelihood of entering the brainstem, deep needling at GB 20 may damage the vertebral artery or deep cervical veins, even when angled toward the nose. Review this anatomy in Figure 11-56.

Muscles

- **Splenius capitis muscle:** Working bilaterally, the splenius capitis muscles extend the head. Working unilaterally, the splenius capitis bends the head in a lateral direction. Liu et al regard GB 20 as the motor point of the splenius capitis.[2]
- **Semispinalis capitis muscle:** Working bilaterally, the semispinalis capitis muscles extend the head. Working unilaterally, the semispinalis capitis rotates the head.
- **Rectus capitis posterior major muscle:** Extends and rotates the head. However, its function as a proprioceptor may be more important than the motion it provides.
- **Obliquus capitis superior muscle:** The obliquus capitis superior muscle, along with its counterpart, the obliquus capitis inferior muscle, as well as the rectus capitis posterior major and minor muscles, are important in posture, and may function as kinesiological monitors, or organs of proprioception, for head position. The obliquus capitis superior muscle extends and laterally bends the atlanto-occipital joint.

Clinical Relevance: Myofascial trigger points in any of the muscles located near GB 20 contribute to head and neck pain. In addition, pain at the back of the head near GB 20 and BL 10 can arise from trigger points in the multifidi, levator scapulae, splenius cervicis, and infraspinatus muscles. Suboccipital trigger points send pain around the lateral cranium from the occipitotemporal region to the eye, traversing GB and TH territories rostral and caudal to the ear.

Both the rectus capitis posterior major and minor muscles help protect the spinal cord and may be implicated in causing head and neck pain. Atrophy of these muscles and inability to maintain standing balance may occur with chronic neck pain. That is, chronic somatic dysfunction in these muscles may cause muscle atrophy and reduced proprioceptive output, leading to loss of balance.[3]

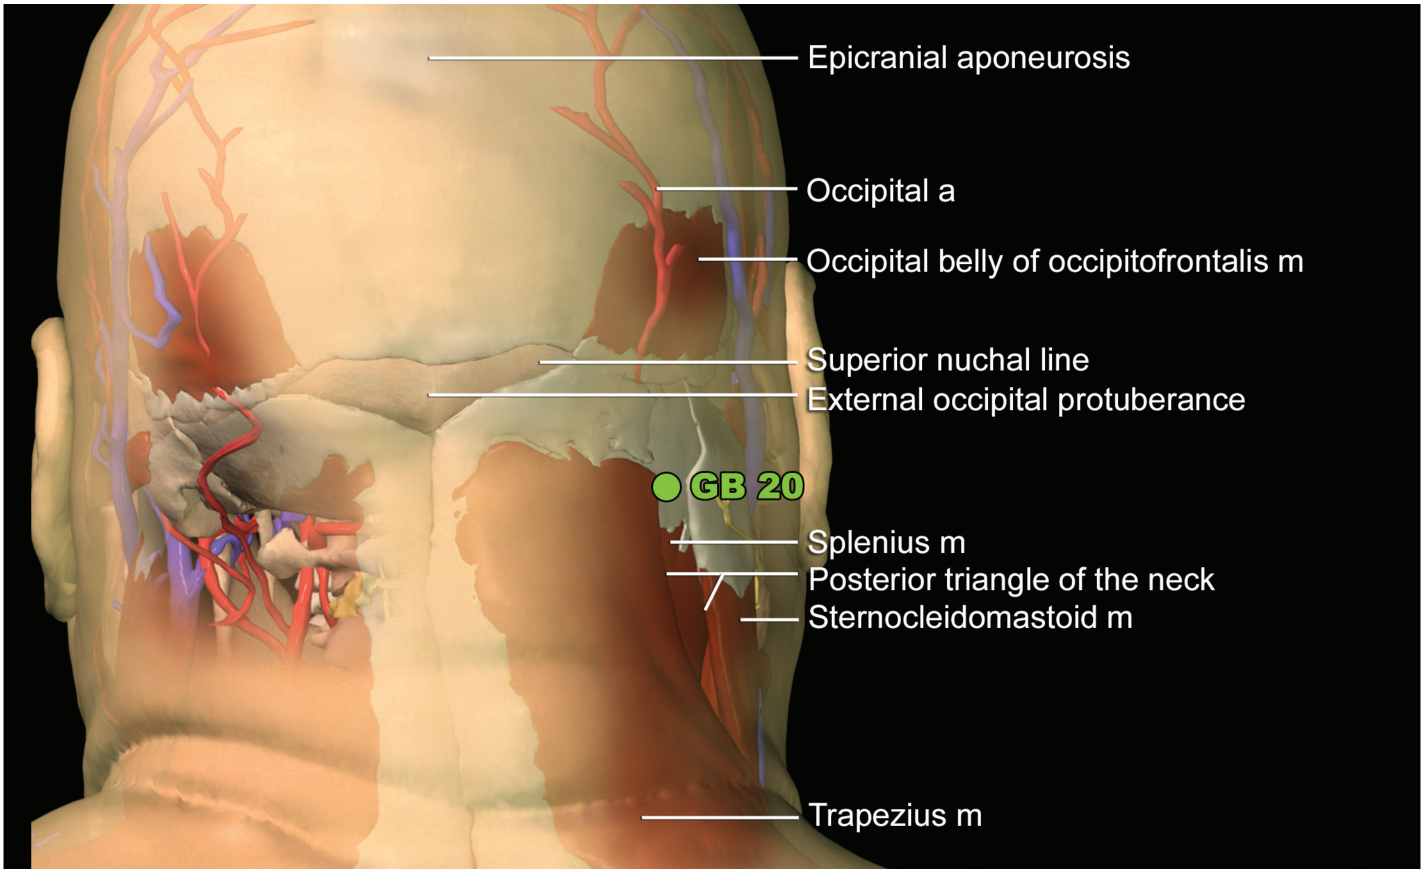

Figure 11-55. "Wind" supposedly "pools" in the depression between the trapezius and SCM at GB 20; hence its name, "Wind Pool". Many individuals exhibit tenderness to palpation at GB 20. GB 20 overlies the motor and trigger points of the splenius capitis muscle; myofascial dysfunction here radiates pain to the vertex. Trigger points in the trapezius muscle, especially from GB 21 in the upper trapezius, radiate pain to GB 20. Note on the left side the way in which the occipital artery makes its way across the superior nuchal line. The greater occipital nerve courses close to the occipital artery though not shown here. Both may incur compression by dint of compression by chronically contracted muscles at their attachment sites on the skull.

Figure 11-56. A needle entering GB 20 would course between the SCM and the trapezius muscles to impact the splenius capitis and semispinalis capitis. Splenius capitis trigger points refer pain to the zone inhabited by GB 18 to GB 15 on either side and include the vertex (GV 20). Semispinalis capitis trigger points refer pain to the temporal region in a band-like fashion, wrapping around the head.

Restriction in the soft tissues in the neck increases the likelihood of compression of neural, vascular, and glandular components in the cervicocephalic region, thereby increasing the possibility for for pain and autonomic dysfunction.

Compare the relationships of GB 20, BL 10, and the suboccipital musculature in Figures 11-56 and 7-22, respectively. Note that while deep needling in these two sites can reach a variety of problematic muscles, it may also enter one or more large vessels, such as the deep cervical veins near the right side of the spine in Figure 11-56.

Nerves

- **Greater occipital nerve (GON) (C2, C3):** Supplies sensation to the skin from the occiput to the vertex. The dorsal roots of C1-C3 also supply sensation to the posterior cranial fossa, along with the vagus nerve. Convergent input between the greater occipital nerve and the trigeminal nerve (which supplies the anterior and middle cranial fossa may help explain why patients with headache often complain of pain in both the front of the head and the back of the upper neck.[4,5] Neuromodulatory inhibition of the greater occipital nerve by inhibiting the trigemino-cervical nociceptive convergence mechanism through somatic afferent stimulation helps reduce the intensity of migraine attacks.[6]
- **Lesser occipital nerve (C2, C3):** Supplies the skin behind the ear, the superior ear, the mastoid area, and possibly a small portion of the skin of the neck.
- **Dorsal rami of upper cervical nerves:** Innervate the semispinalis capitis and splenius capitis muscles.
- **Dorsal ramus of C1 (suboccipital nerve):** Innervates the rectus capitis posterior major and obliquus capitis superior muscle.
- **Spinal nerves C2, C3, and C4:** Carry pain and proprioceptive information from the trapezius and sternocleidomastoid muscles.

Anterograde transport of horseradish peroxidase (HRP) suggested that GB 20 makes connections with the posterior auricular branch of the facial nerve (CN VII), the ventromedial division of the facial nucleus, the accessory facial nucleus, the ventral rami of C2-C3, and the ventral horn of the spinal cord segments C1-C4.[7] (Although GB 20 occurs between the SCM and the trapezius muscles, it may influence nerves supplying intervening fascia and thereby affect afferent input.)

Clinical Relevance: Any of the nerves supplying structures within reach of a needle entering GB 20 may become entrapped in the series of layers involved in cervical anatomy, apparent in Figure 11-56. Nerve entrapment leads to pain and myofascial dysfunction. The GON heads from BL 10 and GB 20 toward GV 20 and receives intensive attention based on its contribution to headaches of all sorts, including migraine (see below).

GON: The GON arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[20] This location coincides with GB 20. As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases. Thus, one of the most remarkable clinical attributes of GB 20 pertains to its proximity to the GON and occipital artery and, therefore, its ability to reduce fascial compression and recuperative neuromodulation.

Convergence between the cervical nerves and trigeminal inputs provides a strong neuroanatomic context supporting the inclusion of points within the upper cervical and trigeminal nerve distribution for head and face pain. This trigemino-cervical convergence can work in a nociceptive excitatory or inhibitory manner, depending on the nature of the stimulation entering the central nervous system. The trigemino-cervical complex forms the anatomic and physiologic basis for this convergence. The complex spans from the trigeminal nucleus caudalis to the C2 and C3 spinal cord segments. The GON provides afferent information from the posterior head to the complex, mainly through the C2 nerve root. Nociceptive input supplied by upper cervical nerves flowing into this neural intersection include afferent stimuli from blood vessels, the dura mater of the posterior cranial fossa, cervical spinal ligaments, joints, and muscles. Furthermore, a direct coupling takes place in the dorsal horn of the spinal cord between cervical afferents and input from the meninges, arguing again for targeting cervical acupuncture points (in addition to points innervated by the trigeminal nerve) in cases of head pain and dural irritation. Chronic pain states that induce neuroplastic changes and central sensitization accentuate the excitability of the synaptic meetings, leading to mutual changes and upregulation in the firing patterns of structures in the trigeminocervical distribution. Neck muscles may tense as a result of the sensorimotor integration facilitated by the central sensitization resulting from chronic nociceptive afferent aggravation of pain pathways. Heightened motor output through alpha- and gamma-motoneurons secondarily activates Ia and II muscle spindle afferents, producing even more motor tone through spinal reflex mechanisms. Irritated dural nociceptors further push the motoneurons to fire, contracting the suboccipital paraspinal muscles. Neuromodulation with acupuncture affects local and central pain modulation circuits and interrupts these reflexes. It reduces central sensitization and muscle tension and improves circulation to the local musculature, thereby reducing nociceptive afferent irritability.

Trigeminocervical neural crosstalk can cause patients to feel pain driven by nociceptive information from structures supplied by upper cervical nerve roots and trigeminal territories. This may confuse where the pain originated in cases of posterior fossa tumor, infratentorial dura mater, neuropathic cervical nerve roots, disturbances in the subcutaneous tissue supplied by the GON, and dissection of the vertebral artery.

Lesser occipital nerve: The lesser occipital nerve may receive communicating branches from the greater occipital nerve. Both occipital nerves pierce the trapezius at the base of the skull and are consequently subject to compression by cervical muscle tension, causing occipital neuralgia. When this occurs, it may worsen cervical tension and perpetuate pain in the occiput.

Cervical spinal nerves: Cervical zygopophysial joints cause chronic neck pain and headache in up to half of patients. Facet joints receive innervation from the medial branches of the spinal nerves C3 to C7; each nerve supplies the joint above and below.

Although percutaneous radiofrequency ablation (RFA) has become an accepted nonsurgical modality for chronic neck pain, serious advents may occur. RFA of the least (3rd) occipital nerve and the nerves supplying the C2-C4 facet joints has led to "dropped head syndrome" in which the patient became unable of extending her neck, inducing a debilitating complication.[21] While acupuncture and related techniques may not be able to repair nerves completely destroyed by RFA, the risk of permanent disability emphasizes the need to address pain and functional compromise with safe and effective approaches such as acupuncture and related techniques before pursuing modalities that can cause irreversible damage.

While several cervical spinal nerves supply the splenius and semispinalis muscles, the second cervical spinal nerve (C2) makes extensive direct connections with the vagus nerve. Thus, pain from hypertonic cervical muscles can provoke autonomic changes along with referred pain patterns, such as the nausea and feeling of "misery" that accompanies migraine by dint of crosstalk between C2 spinal nerve and the vagus.

Vessels

- **Occipital artery:** Arises from the external carotid artery and accompanies the occipital nerve in the occipital region. Its distribution includes the scalp at the back of the head.
- **Occipital vein:** Drains the occipital region of the scalp.
- **Deep cervical artery (from the costocervical trunk, which arises from the subclavian artery):** Supplies the deep cervical muscles.
- **Deep cervical vein:** Receives tributaries from the plexuses around the spinous processes of the cervical vertebrae, and terminates in the lower part of the vertebral vein.

Clinical Relevance: The occipital artery is often a main feeding artery in cases of intracranial dural arteriovenous fistulae.[22] Also, blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[23] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites. Figure 11-55 examines the spatial relationship between GB 20 and the occipital artery while Figure 11-56 exposes the presence of deep cervical veins along the potential course of a needle inserted at GB 20. (Not shown are the lateral internal jugular lymph nodes and the deep occipital lymph nodes that exist in the region.[24]) The deep cervical veins ascend the dorsal surface of the vertebral bodies and are vulnerable to damage with dorsal approaches to cervical spinal surgery.[25] When possible and prudent, nonsurgical approaches to neck pain should be tried before highly invasive maneuvers.

Indications and Potential Point Combinations

- **Myalgias associated with viral infection:** GB 20, GB 21, GV 20, LI 4, ST 36.
- **Headaches:** GB 20, BL 10, check for temporalis, occipitofrontalis, trapezius, and cervical muscle trigger points.
- **Cervical pain and tension:** GB 20, BL 10, additional trigger points depending on distribution of referred pain. SI 3, BL 60, GV 20.
- **Tense upper back:** GB 20, GB 21, associated trigger points. Painful or tense shoulder region: GB 20, palpate SI 11, SI 12, SI 13, TH 15 for trigger points, including LI 15, TH 14.
- **Occipital pain radiating to eye:** GB 20, TH 23, Taiyang.
- **Eye pain:** GB 20, TH 23, BL 2, GV 20.
- **Vertigo, dizziness:** GB 20, BL 10, GB 2, TH 20.
- **Hypertension:** GB 20, TH 18, TH 19, Groove Behind the Ear.
- **Seizures:** GB 20, GV 20, ST 36, Yintang.

Evidence-Based Applications

- Treatment for fever using GV 14, GB 20, and LI 11 in 57 patients with **common cold, influenza, acute tonsillitis, or acute bronchitis** helped normalize vital signs and increased T-lymphocytes.[8]
- Three out of three RCTs supported effectiveness of acupuncture for the treatment of **temporomandibular disorders**, prompting the following treatment recommendation: ST 6, ST 7, SI 18, GV 20, GB 20, BL 10, and LI 4.[9]
- A randomized, placebo-controlled trial suggested that treatment with laser acupuncture at LU 7, LI 4, GB 14, and GB 20 benefits **chronic tension headache**.[10]
- Electrical stimulation at GB 20, LI 4, and bilateral EX-HN5 provided pain relief in patients with **chronic tension headache** and did so without producing significant adverse outcomes.[26]
- Acupuncture at GV 14 and GB 20 effectively treated occipital **neuralgia** in a series of cases.[11]
- Pre-injury electroacupuncture at GB 20 or ST 36 can partly regulate the lipid peroxidation occurring as a consequence of **cerebral ischemia**.[12]
- Electroacupuncture at ST 36 or GB 20 may increase thioredoxin expression which could minimize oxidative modifications of thiol groups of surrounding proteins, thereby helping reduce oxidative damage following **brain ischemia**.[13]
- Case series reported electroacupuncture at GB 14, SI 18, ST 7, GB 20, and LI 4 was effective treatment for peripheral **facial paralysis**.[14]
- Acupuncture at LR 3, SP 6, ST 36, CV 12, LI 4, PC 6, GB 20, GB 14, Taiyang, and GV 20 provided greater effectiveness in prophylaxis of **migraine** compared to flunarizine.[15]
- Acupuncture at LR 3, SP 6, LI 4, GB 20, GV 20, and Taiyang outperformed transcutaneous electrical nerve stimulation and laser therapy in reducing the frequency of **migraine**, although all three treatments were effective.[16]
- Acupuncture applied to GB 20, GB 34, TH 5 produced better results for the treatment of **migraine** than did ST 36, LI 6, and ST 8.[27]
- Acupuncture at SI 3, SI 14, LR 3, BL 10, BL 60, GB 20, GB 34, TH 5, trapezius myofascial trigger point, and the auricular point "cervical spine" provided greater pain relief of **chronic neck pain** compared to massage, but not sham laser.[17]
- Helps **regulate blood flow** in the vertebral and basilar arteries.[18]
- Acupuncture at GB 20, GV 20, GV 14, LU 7, and ST 40 in a case series successfully treated **vertebrobasilar ischemic vertigo**.[19]
- Electroacupuncture applied to GB 20, GV 24, GV 20, and Sishencong outperformed medication for individuals with **posttraumatic stress disorder** after earthquake.[28]
- Electroacupuncture protocols, some of which include GB 20, can improve both **cell-mediated and humoral immunity during craniotomy**.[29]
- Electroacupuncture applied to GB 20, GB 21, LR 3, and LI 4, along with local tender points, reduced **myofascial pain in the upper trapezius muscle**.[30]
- Acupuncture at GB 20, GB 14, BL 2, TH 23, Ex1, ST 1, LI 4, LI 11, and GV 23 significantly benefited patients with **severe dry eye** as compared to artificial tears.[31]
- Acupuncture for **apoplectic aphasia** most often includes GB 20, PC 6, GV 20, HT 5, Yuye, Jinjin, CV 23, SP 6, GV 15, and scalp acupuncture sites called "No. 1, 2, and 3 language sections".[32]

GB 21

Jian Jing "Shoulder Well", "Shoulder Fountain"

Midway between the tip of the spinous process of C7 (near GV 14) and the tip of the acromion, at the crest of the trapezius muscle. Usually treated at the point of maximum tenderness.

Caution: One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1] Therefore, avoid deep needle insertion due to presence of underlying lung and risk of pneumothorax.

Some consider needling GB 21 to be contraindicated during pregnancy because of potential to cause abortion.

Muscles

- **Trapezius muscle, upper fibers:** Elevates the scapula.

Clinical Relevance: The trapezius trigger point at GB 21 refers pain along the GB channel to TH 23 and GB 1. A small focus of pain may also appear at SI 17. Pain occasionally extends to the pinna or lower molars. It is not uncommon for trigger point pathology in the trapezius muscle to aggravate myofascial dysfunction in neighboring muscles, causing headache, TMJ-type pain, and neck stiffness.

A variety of interventions aid in alleviating trigger point pathology in the trapezius muscle, including manual pressure,[7] extracorporeal shock wave therapy,[8] acupuncture,[9] transcutaneous electrical point stimulation,[10] and laser therapy.[11,12]

Nerves

- **Supraclavicular nerve (C3, C4), lateral branches:** Supply the skin over the shoulder.
- **Spinal accessory nerve (CN XI):** Provides motor function to the trapezius.
- **Spinal nerves C2, C3, and C4:** Carry pain and proprioceptive information from the trapezius and SCM muscles.

Clinical Relevance: Neuromodulation applied to GB 21 improves local blood flow to the tissue located at GB 21.[13] This suggests that, at least in part, acupuncture reduces local pain by increasing blood flow and reducing neuropathic pain caused by low oxygenation in the tissue.

Spinal accessory neuropathy most commonly results from iatrogenic injury of the nerve in the posterior triangle.[14] This isolated spinal accessory neuropathy manifests as weakness of the SCM and trapezius. This unsupported shoulder places traction on the brachial plexus causing pain and "shoulder syndrome". If the nerve is not completely severed, acupuncture and related techniques may aid in the recovery of spinal accessory nerve function and shoulder strength.

Thoracic limb amputation can cause both somatic pain in the shoulder rotators as well as sympathetic dysfunction in the "stump" region. Neural blockade of the supraclavicular nerve has been found effective.[15] Likely, neuromodulation by means of acupuncture and related technique could also help. Points associated with the supraclavicular nerve include GB 21 and, more precisely, ST 12 and ST 13.

In the mid-1950s, injection at GB 21 was termed the "master control thoracic splanchnics" (MCTS) point. GB 26 received the

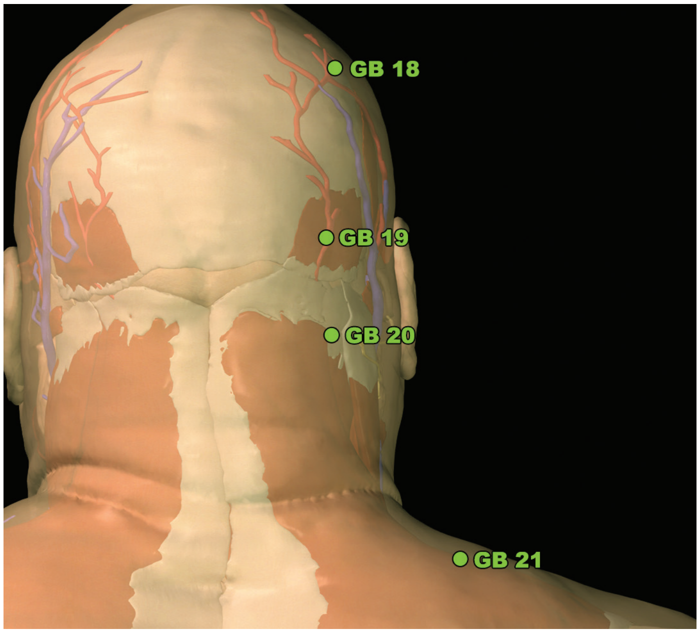

Figure 11-57A. Referred pain from trigger point pathology courses rostrad toward the eye along the GB channel.

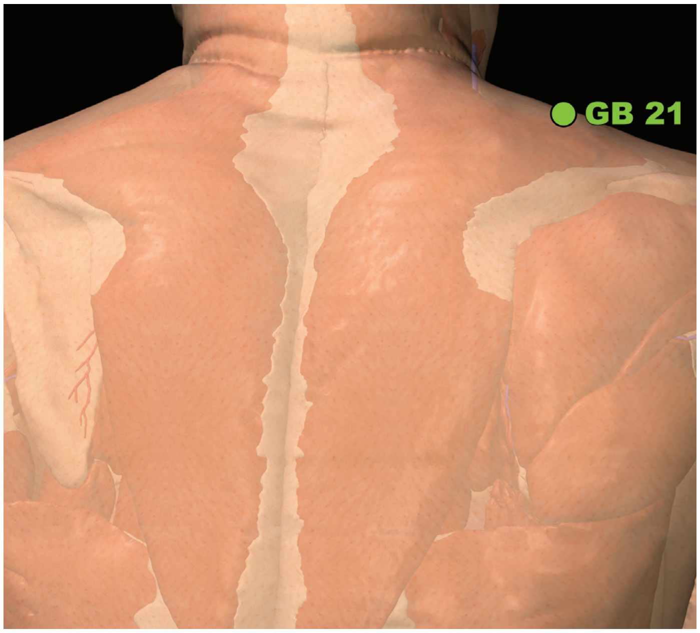

Figure 11-57B. The trapezius muscle extends from the occiput to the caudal thoracic vertebrae and out toward the clavicle, acromion process, and scapular spine bilaterally. The superior, upper, or most cranial fibers elevate the shoulders. They also work in conjunction with the serratus anterior muscle to upwardly rotate the scapulae, as when performing an overhead press exercise. When working with the middle fibers and muscles such as the rhomboids, the upper fibers of the trapezius assist with retracting or adducting the scapulae.

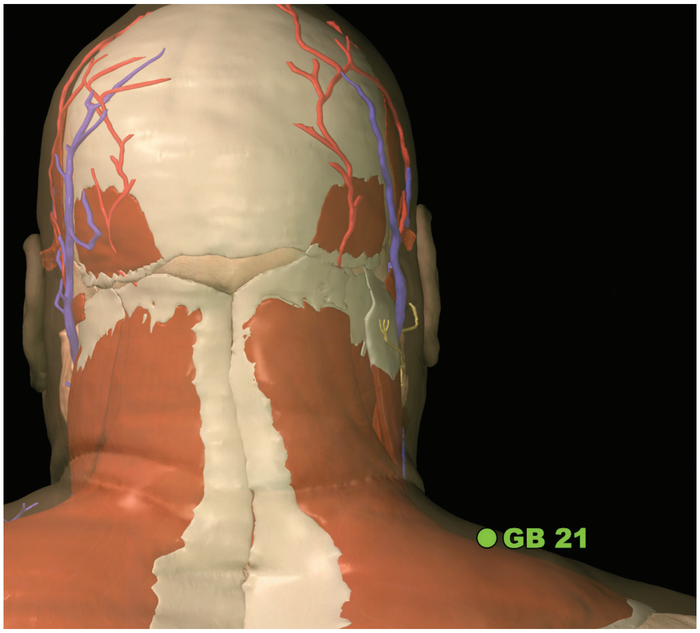

Figure 11-58A. The term "Shoulder Fountain" may refer to the mound of muscle that arises when the trapezius tenses.

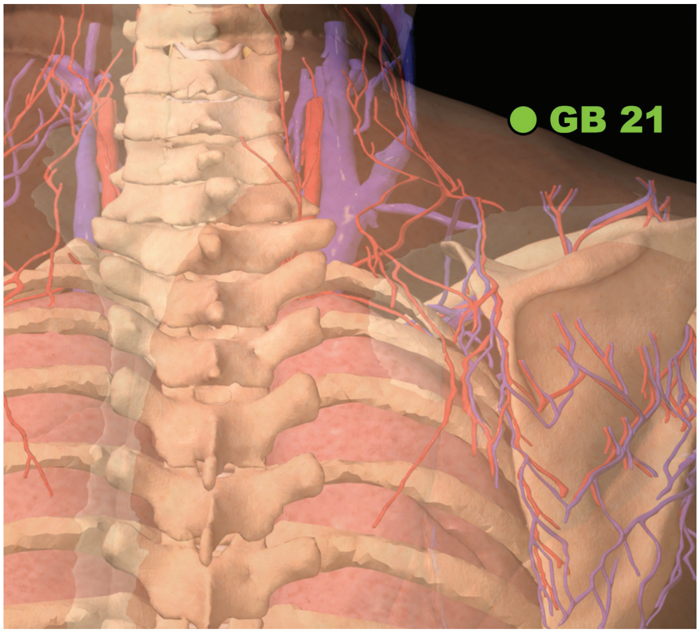

Figure 11-58B. The "basin" of bones beneath GB 21 explains the name, "Shoulder Well". Avoid needling too deeply into the well or you may puncture the lung, especially in emphysematous or thin individuals.

designation as "master control lumbar splanchnics" (MCLS) point. In his 1954 paper, "Further experiences with blocking of cutaneovisceral reflex arcs for relief of sympatheticotonic states; (II) Somatic nerve blocks performed *en passant*, Final Report", Skillern compiled an extensive account of cases he treated by interrupting reflex arcs throughout the body. Patients benefited by nerve blocks applied to GB 21 included those suffering from chronic suppurative sinusitis with accompanying headache, rhinosinusitis interfering with vision, abnormal glandular activity in the head and neck, asthma, angina pectoris, hypertension, pyloric dysfunction and constipation, and biliary colic. He attributed his results to blockade of afferent limbs of somatosympathetic reflex arcs. Nerve block at GB 26 provided relief of appendiceal pain, spastic colon, dysmenorrhea, and urinary discomfort.

The autonomic impact of neuromodulation applied to GB 21 likely arises from somatosympathetic reflexes through cranial thoracic spinal cord segments as well as somatoparasympathetic reflexes by dint of communication between the spinal accessory and vagus nerves. Cranial nerves IX, X, and IX relate to each other anatomically by all exiting the jugular foramen, as well as functionally due to the numerous intercommunicating branches they share and the anastomotic networks they form.[16]

Vessels

- **Transverse cervical artery:** A branch of the thyrocervical trunk, the transverse cervical artery supplies muscles in the posterior cervical triangle, the trapezius muscle, and the medial scapular muscles.
- **Transverse cervical vein:** Drains this region and empties into the external jugular vein.

Clinical Relevance: The transverse cervical artery crosses the phrenic nerve about 3 cm cranial to the clavicle at a right angle; hence the name "Red Cross Syndrome" when ischemic neuropraxia results from arterial compression of the nerve. While it stands anatomically apart from the well-defined prevertebral fascia, surgical, anesthetic, or chiropractic procedures applied to the neck can stretch or transect the nerve. Trauma to the fascia and nerve may result in fibrosis and scarring in the area. Loss of tissue plane separation and adhesion of normally separate anatomical layers invites nerve compression and/or dysfunction.[17] Iatrogenic or traumatic injury to the cervical fascia may similarly impact the transverse cervical artery. Changes to the course and caliber of the artery from anatomical changes, preceding trauma, and/or inflammation can induce further compression of the phrenic nerve that lies deep to it. Phrenic nerve injury in the neck from transverse cervical artery is one source of diaphragm paralysis from peripheral causes.

Needling in the vicinity of GB 21 may augment blood flow through the vertebral and transverse cervical artery.[18] This may aid patients with cerebral blood flow insufficiency.

Acupuncture and related techniques alleviate myofascial restriction in the shoulder to allow better blood flow and improve tissue impair. Points to treat include GB 21, TH 15, SI 14, SI 15, and other relevant trigger points.

Indications and Potential Point Combinations

- **Temporal and cervicogenic headaches:** GB 21, GB 20, TH 18, temporalis/trapezius/SCM trigger points, GV 20. With suspected greater occipital nerve shear stress from trapezius muscle restriction, add GB 19. Consider TH 5 or LI 11 as remote points.[2]
- **"Whiplash" injury:** GB 20, GB 21, SI 16.[19]
- **Tension headache:** GB 21, GB 20, GB 19, temporalis trigger points, GB 14, LR 3, LI 4.
- **Mastitis:** GB 21, SI 1, ST 18.
- **TMJ disorders:** GB 21, GB 2 (or TH 21, SI 19 if tender), tempo-

Figure 11-59. The thickness of the trapezius muscle in this individual would have helped protect the lung from pneumothorax during acupuncture. On the other hand, patients with atrophic musculature will not harbor this barricade to the portal of entry at GB 21 to the lung. Hyperinflated lungs increase the risk of inadvertent organ puncture.

ralis trigger points, consider ST 6.

- **Tension fatigue in singers:**[3] GB21, SCM trigger points
- **Asthma:** GB 21, BL 13, LI 10, LI 4, LU 2, GV 14. Assess the cervical accessory muscles of respiration (upper trapezius, scalenes, cervical paraspinal, and SCM muscles) and the masticatory muscles involved with mouth breathing (temporalis, masseter, pterygoid muscles) in order to reduce additional myofascial pain and stress.[4]
- **Dizziness or vertigo:** May result from a trigger point at GB 21; also consider triggers in the SCM.
- **Neck and shoulder tension:** GB 21 and local trigger points

Evidence-Based Applications

- GB 21 demonstrated higher **cutaneous and subcutaneous blood flow** compared to an adjacent asymptomatic reference point within the trapezius muscle.[5] This supports the contention that acupuncture points normally exhibit increased microcirculatory input than non-acupuncture points. It also provides a basis for noninvasively assessing blood flow to points that, when afflicted by myofascial dysfunction, experience reduced blood flow, as when trigger points coalesce the tissue at that site.
- Physicians in Germany considered GB 21, GB 20, and LR 3 to be three "basic" points for the treatment of **tension headache.** They frequently included LI 4, SP 6, and ST 36 as well.[6]
- Aquapuncture injection at GB 21, GB 20, and Taiyang using safflower seed solution significantly reduced morbidity from **chronic daily headache.**[20]
- Acupuncture at GB 21, LU 1, LI 11, LI 4, TH 3, and TH 5 **reduced postoperative pain in patients after arthroscopic shoulder surgery.** Patients receiving acupuncture also slept better.[21]
- Bee-venom injection aided in reducing **shoulder pain** when applied to GB 21.[22]
- Acupuncture at GB 21 alleviated shoulder, back pain, and abdominal pain as well as regulated gallbladder volume in patients with **chronic cholecystitis.**[23]
- Acupuncture at GB 21 regulates **gallbladder activity.**[24]
- Acupuncture at GB 21, SI 14, and SI 15 significantly influenced autonomic nervous system activity in patients with **chronic neck pain.**[25]

GB 22

Yuan Ye "Armpit Abyss"

On the mid-axillary line, at the level of the 4th intercostal space, approximately 3 cun caudal to the ventral axillary fold. Palpate for a tender point.

Some sources locate this point at the 5th intercostal space. To find the 5th intercostal space, first find the 2nd. It lands on the lateral border of the sternum, in the intercostal groove adjacent and caudal to the sternal angle. Identify the 5th intercostal space and follow it to the mid-axillary line.

Muscles

- **Serratus anterior muscle:** Protracts and rotates the scapula; holds it against the thoracic wall. Myofascial dysfunction of the serratus anterior can arise from long thoracic nerve injury.
- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.

Clinical Relevance: The serratus anterior muscle arises from the cranial eight or nine ribs and inserts on the medical scapular border. It exhibits three portions (upper, middle, and lower) that assist in controlling the scapulae during thoracic limb activities.[3] The serratus anterior stabilizes the scapula; denervation or compromise of the long thoracic nerve leads to scapular "winging". Unbeknownst to many, the serratus anterior may engender painful conditions of the neck and shoulder; this connection arises in part from the muscle's impact on posture of the upper back. Persons who experience neck pain secondary to thoracic limb movements should be examined for serratus anterior dysfunction.

Trigger points in the serratus anterior muscle at GB 22 and GB 23 cause intense local pain or local pain plus referred patterns from the chest to the palm along the PC and HT lines.

Trigger points in the intercostal muscles at GB 22 and GB 23 incite mainly local pain. When severe myofascial dysfunction exists, the pain travels toward the sternum rather than the back. Patients may complain of having a "stitch in the side", although diaphragmatic trigger points may also cause this symptom. Acupuncture of the intercostal muscles risks causing pneumothorax; acupressure, medical massage, soft tissue manipulation, and laser therapy are therefore preferred modalities to treat intercostal muscle trigger points. Stretching or yoga may also help, along with corrective deep breathing exercises.

Nerves

- **Long thoracic nerve (C5-C7):** Innervates the anterior serratus muscle.
- **4th (or 5th) intercostal nerve:** Innervates the external and internal intercostal muscles; innervates the skin via lateral cutaneous branches.

Clinical Relevance: Neuropathy of the long thoracic nerve can lead to notalgia paresthetica, a poorly understood condition characterized by pruritus and/or pain. Proposed etiologies of notalgia paresthetica include degenerative changes of the T2-T6 vertebrae, nerve entrapment of the posterior rami of the T2-T6 spinal nerves, or genetic predisposition. Serratus anterior dysfunction may also result from irritability of the long thoracic nerve.[1] The long thoracic nerve emerges through the middle

Figure 11-60. GB 22 and GB 23 sit side-by-side in the 4th intercostal space, adjacent to the lung as shown here. GB 22, with the alternate name of the "water source", was once regarded as an origin of perspiration. Intercostal nerves branch at the mid-axillary line, coincident with GB 22. Intercostal neuralgia may arise from gigantomastia secondary to chronic stretch and resultant neuropathy.

scalene muscle; myofascial dysfunction in the middle scalene may irritate the long thoracic nerve and lead to serratus anterior dysfunction and trigger points.

Intercostal nerves four through six course along the lateral pectoralis fascia and then branch into the breast parenchyma. Sensory branches separate from the intercostal nerves in the mid-axillary line,[4] which makes GB 22 and GB 23 relevant in this regard. Surgery, irradiation, or other procedures near the breast and GB 22 or GB 23 may damage local nerves and their supporting structures. This has the potential to induce chronic breast pain and neuroma formation.[5] Intercostal neuromas following breast surgery may affect one or more intercostal nerves along the lateral chest wall. Intercostal neuralgia produces pain of a burning, electrical, or stabbing type.[6] Causes include breast surgery, pregnancy, and herpes zoster infection. Intercostal neuralgia is frequently refractory to pharmaceutical and surgical interventions. While thoracic dorsal rhizotomy at multiple levels has been reported as successful, neuroablative procedures should be reserved for those cases where less invasive approaches have failed. Myofascial sources of chest wall pain have likely escaped notice by conventional practitioners who omit palpation and a search for trigger points from their patient examination.

Phantom breast pain following mastectomy causes an unpleasant sensation in the location of the removed breast. Patients may develop sympathetically medicate pain after reduction mammoplasty as well. Pathophysiology involves deafferentation of neurons with resultant evoked and spontaneous hyperexcitability.[7] Reflex sympathetic dystrophy perpetuates pain and circulatory abnormalities in the vicinity.

Acupuncture, massage, and related techniques may aid in reducing nerve-based pain and myofascial restriction contributing to the problem.

Vessels

- **Anterior intercostal artery:** Derived from the internal thoracic arteries, the 4th (or 5th) anterior intercostal arteries supply the 4th (or 5th) intercostal muscles, the pectoral muscles, the breasts, and the skin.
- **Anterior intercostal vein:** These are tributaries of the internal thoracic veins and accompany the intercostal arteries.

Clinical Relevance: Reduced blood supply from muscle tension and connective tissue fibrosis reduces arterial blood supply and venous and lymphatic drainage. This can compromise health of the regions supplied, including breast health.

Indications and Potential Point Combinations

- **Lateral costal pain:** GB 22, local trigger points. If radiating along ulnar aspect of the thoracic limb, examine serratus anterior for trigger points in the GB 23 and GB 22 region; add HT 3, HT 7, and SI 3. This type of pain my co-occur with myocardial infarction.
- **A feeling of fullness or weakness in the chest:** GB 22, CV 17, LU 2.
- **Mastalgia (abnormally sensitive breast):** Consider serratus anterior trigger point at GB 22, GB 23. Also examine pectoralis major muscle for trigger points near LU 1, LU 2.

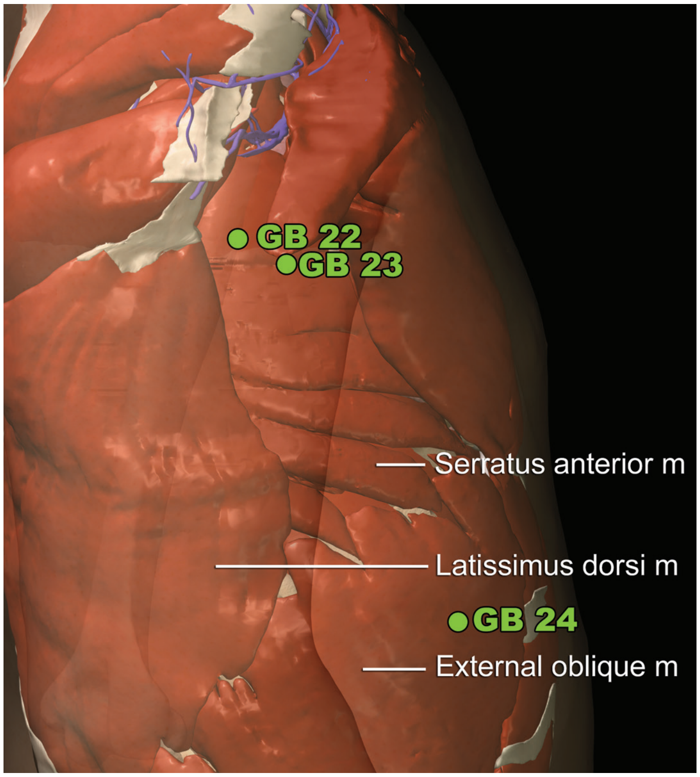

Figure 11-61. A tender spot in the serratus anterior muscle designates the location of GB 22, about a hand's breadth caudal to the axillary fold.

- **Pleuritic pain:** GB 22 or GB 23, LR 14, LU 2.
- **Intercostal neuralgia:** GB 22, trigger points along the involved intercostal level.
- **Feeling of air hunger, difficulty expressed concerning inability to fully inhale and expand the chest; worse when holding telephone up to the ear:** Consider serratus anterior trigger point at GB 22, GB 23. Examine pectoralis major muscle for trigger points at LU 1, LU 2. Add BL 16, BL 17 or BL 45 and BL 46.
- **Inability to fully adduct the scapula:** Consider serratus anterior trigger point at GB 22, GB 23.
- **Interscapular pain, potentially worsened by upper body exercise including fast running, push-ups, lifting heavy weights overhead, loading baggage into the overhead compartment on an airplane, or severe coughing from respiratory ailments:** Consider serratus anterior trigger point at GB 22, GB 23.
- **Notalgia paresthetica:** GB 22, GB 23, BL 12 through BL 16, BL 41 through BL 45. Examine middle scalene muscle for myofascial trigger points. Consider LI 18 or LI 19 if palpably tender.
- **Round-shouldered posture with prominence of the spine and superior border of the scapula:** Examine for serratus anterior trigger points at GB 22, GB 23. Recommend full body massage and stretching to restore proper alignment of the spine and more healthful posture. Consider yoga.

Evidence-Based Applications

- Electrical stimulation of the serratus anterior muscle in the vicinity of GB 22 and GB 23 provided relief of the pruritus and pain of **notalgia paresthetica.**[2]

GB 23

Zhe Jin "Sinew Seat"

On the lateral chest wall, in the 4th intercostal space, 1 cun ventral to GB 22. Refer to Figure 11-62 for its relationship to other structures in cross section.

Some sources locate GB 23, like GB 22, in the 5th intercostal space.

Muscles

- **Serratus anterior muscle:** Protracts and rotates the scapula; holds it against the thoracic wall. Myofascial dysfunction of the serratus anterior can arise from long thoracic nerve injury.
- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.

Clinical Relevance: The serratus anterior muscle arises from the cranial eight or nine ribs and inserts on the medical scapular border. It exhibits three portions (upper, middle, and lower) that assist in controlling the scapulae during thoracic limb activities.[3] The serratus anterior stabilizes the scapula; denervation or compromise of the long thoracic nerve leads to scapular "winging". Unbeknownst to many, the serratus anterior may engender painful conditions of the neck and shoulder; this connection arises in part from the muscle's impact on posture of the upper back. Persons who experience neck pain secondary to thoracic limb movements should be examined for serratus anterior dysfunction.

Trigger points in the serratus anterior muscle at GB 22 and GB 23 cause intense local pain or local pain plus referred patterns from the chest to the palm and fingers along the PC and HT lines.

Trigger points in the intercostal muscles at GB 22 and GB 23 incite mainly local pain. When severe myofascial dysfunction exists, the pain travels toward the sternum rather than the back. Patients may complain of having a "stitch in the side", although diaphragmatic trigger points may also cause this symptom. Acupuncture of the intercostal muscles risks causing pneumothorax; acupressure, medical massage, soft tissue manipulation, and laser therapy are therefore preferred modalities to treat intercostal muscle trigger points. Stretching or yoga may also help, along with corrective deep breathing exercises.

Nerves

- **Long thoracic nerve (C5-C7):** Innervates the anterior serratus muscle. Neuropathy of the long thoracic nerve can lead to notalgia paresthetica, a poorly understood condition characterized by pruritus and/or pain. Proposed etiologies of notalgia paresthetica include degenerative changes of the T2-T6 vertebrae, nerve entrapment of the posterior rami of the T2-T6 spinal nerves, or genetic predisposition. Serratus anterior dysfunction may also result from irritability of the long thoracic nerve.[1] The long thoracic nerve emerges through the middle scalene muscle; myofascial dysfunction in the middle scalene may irritate the long thoracic nerve and lead to serratus anterior dysfunction and trigger points.
- **Fourth (or 5th) intercostal nerve:** Innervates the external and internal intercostal muscles; innervates the skin via lateral cutaneous branches.

Clinical Relevance: Neuropathy of the long thoracic nerve can lead to notalgia paresthetica, a poorly understood condition characterized by pruritus and/or pain. Proposed etiologies of notalgia paresthetica include degenerative changes of the T2-T6 vertebrae, nerve entrapment of the posterior rami of the T2-T6 spinal nerves, or genetic predisposition. Serratus anterior dysfunction may also result from irritability of the long thoracic nerve.[1] The long thoracic nerve emerges through the middle scalene muscle; myofascial dysfunction in the middle scalene may irritate the long thoracic nerve and lead to serratus anterior dysfunction and trigger points.

Intercostal nerves four through six course along the lateral pectoralis fascia and then branch into the breast parenchyma. Sensory branches separate from the intercostal nerves in the mid-axillary line,[4] which makes GB 22 and GB 23 relevant in this regard. Surgery, irradiation, or other procedures near the breast and GB 22 or GB 23 may damage local nerves and their supporting structures. This has the potential to induce chronic breast pain and neuroma formation.[5] Intercostal neuromas following breast surgery may affect one or more intercostal nerves along the lateral chest wall. Intercostal neuralgia produces pain of a burning, electrical, or stabbing type.[6] Causes include breast surgery, pregnancy, and herpes zoster infection. Intercostal neuralgia is frequently refractory to pharmaceutical and surgical interventions. While thoracic dorsal rhizotomy at multiple levels has been reported as successful, neuroablative procedures should be reserved for those cases where less invasive approaches have failed. Myofascial sources of chest wall pain have likely escaped notice by conventional practitioners who

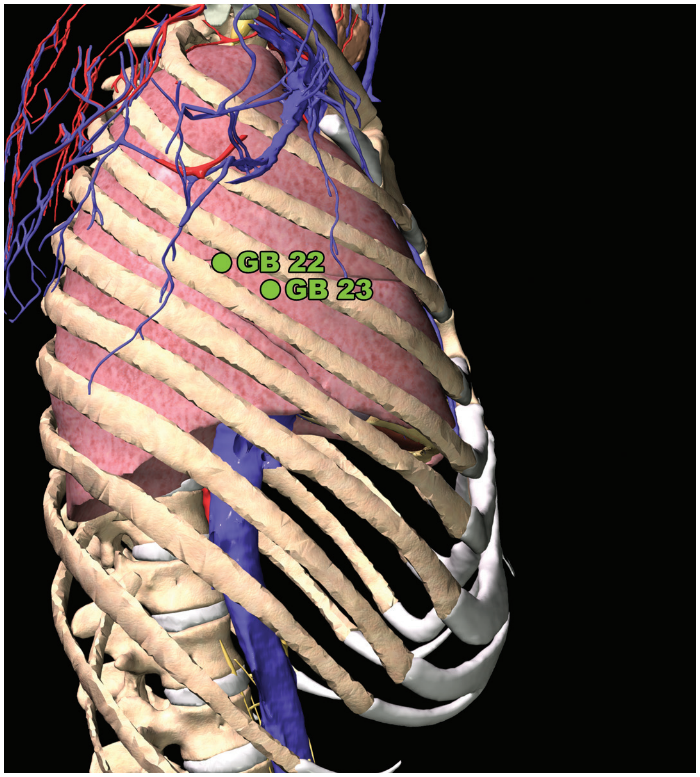

Figure 11-63. The name for GB 23 of "Sinew Seat" refers to the intercostal muscles riding between the ribs, as if in the seat of a chariot. To the ancient Chinese acupuncturists, the shape of the rib cage resembled that of a chariot as it rests on its wheels.

omit palpation and a search for trigger points from their patient examination.

Phantom breast pain following mastectomy causes an unpleasant sensation in the location of the removed breast. Patients may develop sympathetically medicate pain after reduction mammoplasty as well. Pathophysiology involves deafferentation of neurons with resultant evoked and spontaneous hyperexcitability.[7] Reflex sympathetic dystrophy perpetuates pain and circulatory abnormalities in the vicinity.

Acupuncture, massage, and related techniques may aid in reducing nerve-based pain and myofascial restriction contributing to the problem.

Vessels

- **Anterior intercostal artery:** Derived from the internal thoracic arteries, the 4th (or 5th) anterior intercostal arteries supply the 4th (or 5th) intercostal muscles, the pectoral muscles, the breasts, and the skin.
- **Anterior intercostal vein:** These are tributaries of the internal thoracic veins and accompany the intercostal arteries.

Clinical Relevance: Reduced blood supply from muscle tension and connective tissue fibrosis reduces arterial blood supply and venous and lymphatic drainage. This can compromise health of the regions supplied, including breast health.

Indications and Potential Point Combinations

- **Lateral costal pain:** GB 23, local trigger points. If radiating along ulnar aspect of the thoracic limb, examine serratus anterior for trigger points in the GB 23 and GB 22 region; add HT 3, HT 7, and SI 3.This type of pain my co-occur with myocardial infarction.
- **A feeling of fullness or weakness in the chest:** GB 23, CV 17, LU 2.
- **Mastalgia (abnormally sensitive breast):** Consider serratus anterior trigger point at GB 22, GB 23. Also examine pectoralis major muscle for trigger points near LU 1, LU 2.
- **Pleuritic pain:** GB 23, LR 14, LU 2.
- **Intercostal neuralgia:** GB 23, trigger points along the involved intercostal level.
- **Feeling of air hunger, difficulty expressed concerning inability to fully inhale and expand the chest; worse when holding telephone up to the ear:** Consider serratus anterior trigger point at GB 22, GB 23. Examine pectoralis major muscle for trigger points at LU 1, LU 2. Add BL 16, BL 17 or BL 45 and BL 46.
- **Axillary adenitis:** GB 23, HT 2, ST 36.
- **Inability to fully adduct the scapula:** Consider serratus anterior trigger point at GB 22, GB 23.
- **Interscapular pain, potentially worsened by upper body exercise including fast running, push-ups, lifting heavy weights overhead, loading baggage into the overhead compartment on an airplane, or severe coughing from respiratory ailments:** Consider serratus anterior trigger point at GB 22, GB 23.
- **Notalgia paresthetica:** GB 22, GB 23, BL 12 through BL 16, BL 41 through BL 45. Examine middle scalene muscle for myofascial trigger points. Consider LI 18 or LI 19 if palpably tender.
- **Round-shouldered posture with prominence of the spine and superior border of the scapula:** Examine for serratus anterior trigger points at GB 22, GB 23. Recommend full body massage and stretching to restore proper alignment of the spine and more healthful posture. Consider yoga.

Evidence-Based Application

- Electrical stimulation of the serratus anterior muscle in the vicinity **of GB 22 and GB 23 provided relief of the pruritus and pain of notalgia paresthetica.**[2]

GB 24

Ri Yue "Sun and Moon"

Inferior to the nipple, on the mid-clavicular line, in the 7th intercostal space, 1 intercostal space caudal to and slightly lateral to LR 14.

Alternate location (GB 24′): Immediately caudal to the costal margin, on the mid-clavicular line. Compare the placement of GB 24 and "GB 24′ " in Figure 11-64.

Muscles

- **External oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.
- **Transversus abdominis muscle:** Compresses and supports the abdominal viscera. Since this is the deepest layer of the muscles of the abdominal wall, needling through this muscle may damage internal organs.

Clinical Relevance: Referred pain patterns from trigger points in the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress.

Trigger point pathology in the abdominal oblique muscles may send referred pain in various directions across the abdomen, including toward the ipsilateral or contralateral subcostal margin, the umbilicus, the groin, and/or the genitalia, leading to a variety of diagnostic enigmas and confusion. Attachment trigger points arise along the hypochondrial region as in GB 24, as well as along the iliac crest (GB 26 and GB 27). Trigger points near the subchondral region refer pain to the mid-epigastrium toward the opposite wing of the ilium.

Trigger points in the cranial portion of the transverses abdominis muscle refer pain across the epigastrium around the xyphoid process between the anterior costal margins. Some evidence exists that the transversus abdominis and pelvic floor muscles contract together. Activating the transversus abdominis may increase urethral pressure and aid women with urinary incontinence that have difficulty exercising the pelvic floor muscles.[6] Stimulation of local afferents with acupuncture and related techniques may aid in recovery of continence.

Trigger points in the intercostal muscles at GB 24, when the point is treated within the 7th intercostal space, incite mainly local pain. When severe myofascial dysfunction exists, the pain travels toward the sternum rather than the back. Patients may complain of having a "stitch in the side", although diaphragmatic trigger points may also cause this symptom. The external intercostal muscles contain more muscle spindles than the internal intercostal muscles; those in the first seven intercostal spaces exhibit a greater density of muscle spindles than do the muscles in the lower intercostal spaces.

Acupuncture of the intercostal muscles risks causing pneumothorax; acupressure, medical massage, soft tissue manipulation, and laser therapy are therefore preferred modalities to treat intercostal muscle trigger points. Stretching or yoga may also help, along with corrective deep breathing exercises.

Nerves

- **Thoracoabdominal nerves (T7-T11):** Innervate the external and internal oblique muscles and the transverse abdominal muscle.

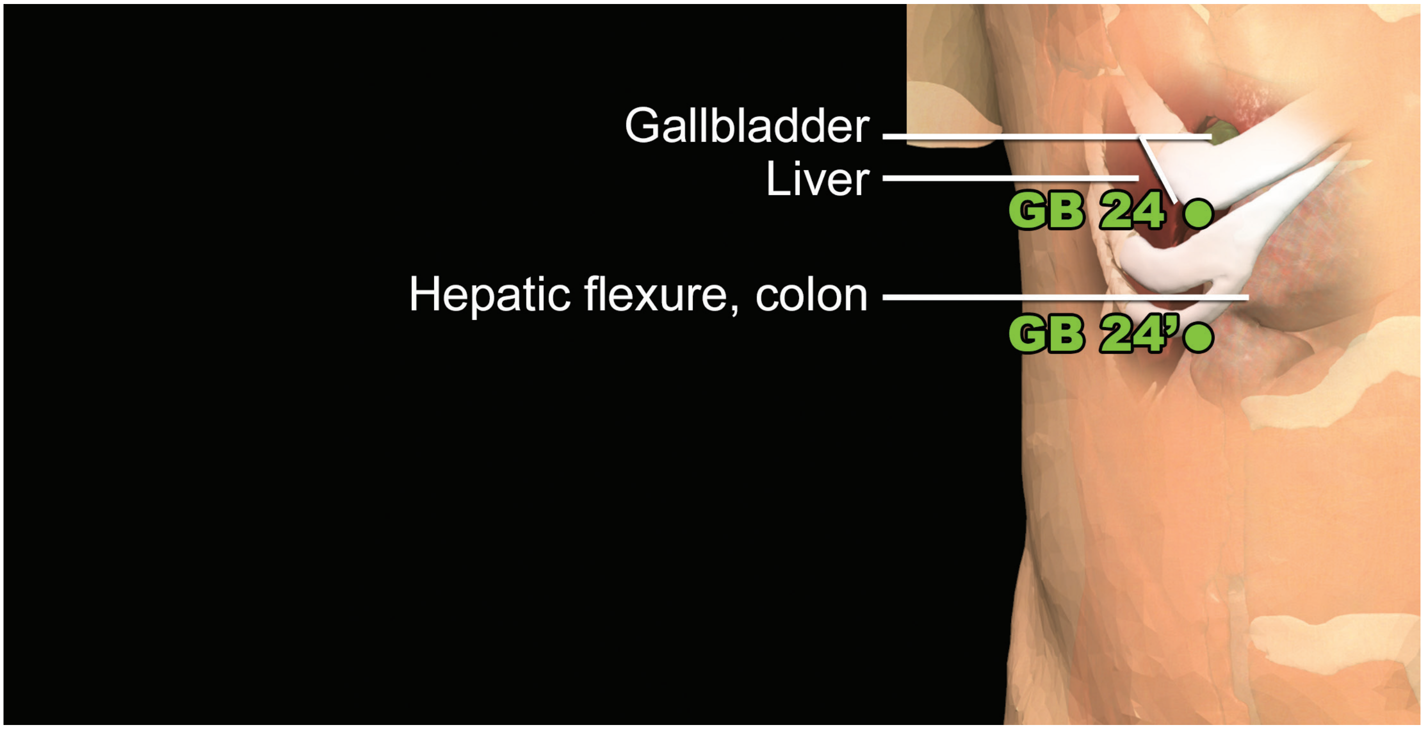

Figure 11-64. GB 24, the "Sun and Moon", lives either within the last full intercostal space on the mid-clavicular line (which may be the 7th intercostal space) or at the intersection of the mid-clavicular line and the subchondral border. Note in this image how the placement of the point affects the organ it overlies. Here, GB 24 lands directly over the gallbladder when located within the most caudal yet complete intercostal space. Subchondral placement puts it over the hepatic (right) colonic flexure, denoted by GB 24′.

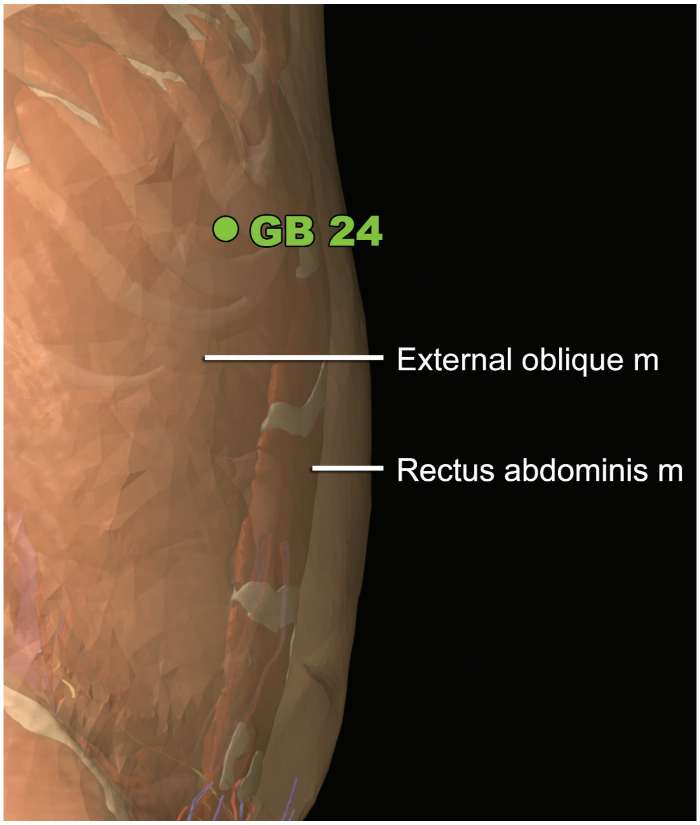

Figure 11-65. GB 24, whether below the ribs or within the 7th intercostal space, targets trigger points along the anterior abdominal wall.

- **Subcostal nerve:** Innervates the external oblique muscle.
- **7th intercostal nerve:** Innervates the external and internal intercostal nerves.
- **7th intercostal nerve:** Innervates the skin via lateral cutaneous branches.

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[7] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from these plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively.

Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu points such as GB 24 or others actually cause changes in several spinal cord segments rather than only one level, which works toward the acupuncturist's advantage by distributing the neuromodulation to a broader territory.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[8] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[9] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[10] Paresis of the abdominal wall may cause large swelling and mechanical complaints.

Intercostal neuralgia produces pain of a burning, electrical, or stabbing type.[11,12] When the 7th intercostal location is selected for GB 24, intercostal nerve pain may be the source of abdominal wall discomfort here.

Vessels

- **Anterior intercostal artery:** Derived from the musculophrenic arteries (branches of the internal thoracic arteries), the 7th anterior intercostal arteries supply the 7th intercostal muscles, the pectoral muscles, the breasts, and the skin.
- **Anterior intercostal vein:** These are tributaries of the internal thoracic veins and accompany the intercostal arteries.

Clinical Relevance: Reduced blood supply from muscle tension and connective tissue fibrosis reduces arterial blood supply and venous and lymphatic drainage.

Indications and Potential Point Combinations

- **Hepatobiliary problems such as cholecystitis, hepatitis:** GB 24, LR 14, ST 36, BL 18, BL 19.
- **Hiccup (Hiccough):** GB 24 and other points along the diaphragmatic attachment sites around the trunk that may be signaling or perpetuating hiccup. PC 6. Consider adding points in the concha of the ear to neuromodulate the auricular branch of the vagus nerve. For hiccup that is further provoked by trigeminal nerve afferents over the skin, add M-CP-18, or Jiachenjiang over the mental foramen.[1] Additional nerve pathways to explore include the phrenic nerve (originating from C2-C5 spinal nerves) and the recurrent laryngeal nerve. Given that the hiccup-reflex arc consists of several neural pathways, pinpointing the etiology and definitive neuromodulatory treatment can be challenging, especially in patients with advanced cancer. In those situations, the multifaceted contributions can include electrolyte disturbances, chemotherapy, esophagitis, or neoplastic involvement of the thoracoabdominal cavities and the nervous system.[2] The vagus nerve, phrenic nerve (C2-C4), and the sympathetic chain (T6-T12) all carry afferent signals to the central hiccup center. The vagus nerve could become irritated anywhere along its course from the abdomen to the brain; as such, trigger points in the anterior cervical region should be examined to determine whether they are compressing the vagus nerve on its way into the jugular foramen.

The auricular branch of the vagus nerve (i.e., Arnold's nerve) could also cause hiccups due to irritation within the auditory canal caused by excessive cerumen, foreign body, or hair.[3]

- **Intercostal neuralgia:** Locate source of pain through palpation; possibly GB 24.
- **Fullness under the ribs:** GB 24, CV 12.
- **Digestive discomfort:** GB 24, ST 36, ST 25, appropriate trigger points or autonomic points based on specific problem.
- **Vomiting:** GB 24, PC 6, GV 20.
- **Gastritis:** GB 24, CV 12, ST 36.

Evidence-Based Applications

- Aquapuncture with water as the fluid into the most sensitive location in a zone outlined by LR 14, GB 24, and CV 14 produced pain relief in a significant number of patients suffering from **biliary colic.**[4]
- A Chinese study compared electroacupuncture at GB 24, GB 34, LR 15, ST 21, BL 18, and Dannang (EX-LE 6) to a control intervention consisting of the Chinese herb Paishi Decoction, magnesium sulfate, hydrochloric acid, and a fat-laden diet for the treatment of **cholelithiasis** in the biliary tract. The study reported a significant difference between the two groups, with the electroacupuncture group showing better results.[5]

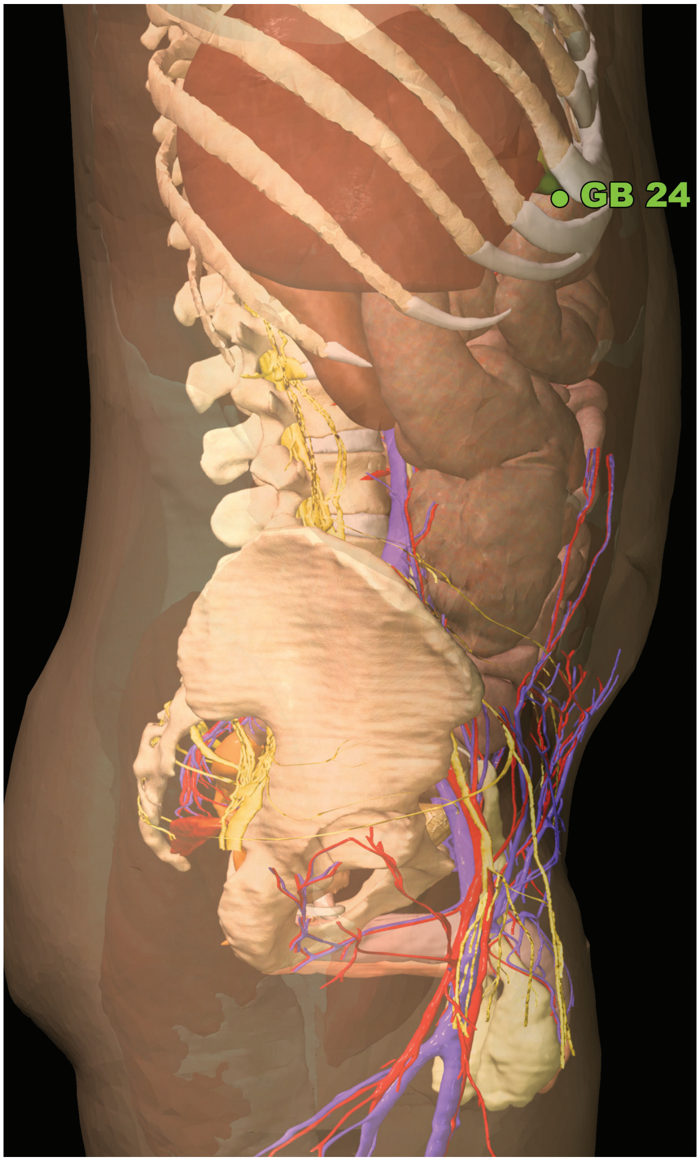

Figure 11-66. GB 24, the Front Mu or "Alarm" point of the gallbladder, resides near the actual gallbladder in the same way that LR 14, the Front Mu point of the liver, lands adjacent to its organ affiliate. With respect to the point's name, the gallbladder represents the "sun" and the liver the "moon" in this Yang-Yin pair.

Figure 11-67. The safe depth of needling for GB 24 depends on the thickness of the muscle and fat over the abdominal wall. As shown in this cross section, overzealous needling through the 7th intercostal space could enter the abdomen and cause damage to the liver or colon. Needling too deeply at a higher level could conceivably enter the gallbladder. On the other hand, cross sections such as this expose several opportunities to introduce laser therapy for organ benefit. Consider, too, the value of carefully applied manipulative therapy for visceral relief from restrictive adhesions and sluggish function.

GB 25

Jing Men "Capital Gate"

Near the mid-axillary line, ventral and caudal to the tip of the 12th (last) rib.

Muscles

- **External oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **Internal oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **Transverse abdominal muscle:** Compresses and supports the abdominal viscera. Since this is the deepest layer of the muscles of the abdominal wall, needling through this muscle may damage internal organs.

Clinical Relevance: Referred pain from trigger points in the abdominal oblique and transversus muscles can lead to visceral symptoms such as "heartburn" and epigastric distress.

Or, referred pain may course in various directions across the abdomen. It may travel toward the ipsilateral or contralateral subcostal margin, the umbilicus, the groin, and/or the genitalia, leading to a variety of diagnostic enigmas and confusion.

Some evidence exists that the transversus abdominis and pelvic floor muscles contract together. Activating the transversus abdominis may increase urethral pressure and aid women with urinary incontinence that have difficulty exercising the pelvic floor muscles.[6] Stimulation of local afferents with acupuncture and related techniques may aid in recovery of continence. Points to consider include GB 25, BL 23, sacral nerve points (BL 31-34) and tibial nerve sites (SP 6, KI 3).

Nerves

- **Thoracoabdominal nerves (T7-T11):** Innervate the external and internal oblique muscles and the transverses abdominal.
- **Subcostal nerve (T12):** Innervates the external oblique muscle.
- **Iliohypogastric nerve (L1):** Supplies the skin over the iliac crest and in the hypogastric region. Supplies the internal oblique and transverse abdominal muscles.
- **Ilioinguinal nerve (L1):** Supplies the skin of the scrotum or labia majora, mons pubis, and that region of the medial thigh that is immediately adjacent. Penile nerves enter the Ilioinguinal nerves as well as the perineal, the dorsal penile, and pudendal nerves, terminating in the cord from T12 to S4.[2] Also innervates the internal oblique and transverse abdominal muscles. See also the iliohypogastric nerve.
- **11th intercostal nerve:** Innervates the skin and subcutaneous tissue.

Clinical Relevance: Patients with chronic low back pain exhibit a variety of neurophysiologic changes that includes autonomic nervous system imbalances. Neuromodulation by means of acupuncture and related techniques improves autonomic status as well as relieves the pain of myofascial dysfunction, thereby aiding back pain patients in a multi-mechanism fashion. GB and BL points aid in achieving this goal.[7]

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[8] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[9] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves. Note the anatomy of the body wall musculature at GB 25 in Figure 11-70. Nerves coursing from the spinal cord to the ventral midline make their way through several fascial layers that could potentially place excess pressure upon them.

When abdominal surgery injures nerves traveling through one or more of these planes, paresis of the rectus abdominis muscle may result, followed by bulging of the abdominal wall.[10] Paresis of the abdominal wall can cause large swelling and digestive or mechanical complaints.

About 10% of patients experience chronic inguinal pain following hernia repair; this pain ordinarily begins right after surgery.[1] While most post-hernia inguinal discomfort results from nociceptive pain arising from somatic or visceral sources, the second most frequent pain originates from surgical injury to the Ilioinguinal, iliohypogastric, or genitofemoral nerve. Acupuncture and related techniques may provide relief through

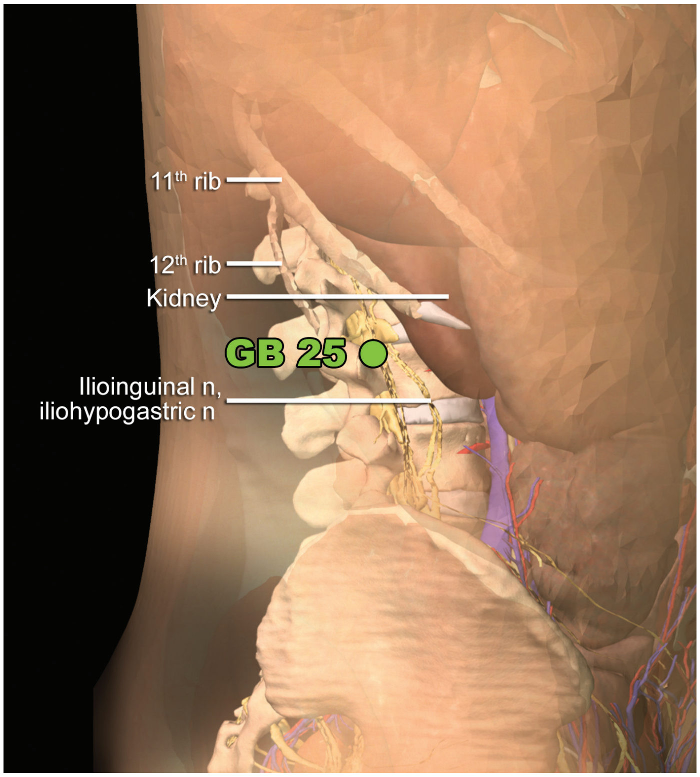

Figure 11-68. GB 25, "Capital Gate", refers to the position of GB 25 in relation to the kidney, considered one of the most important organs in Chinese medicine. This "door to the capital" (i.e., the kidney) sits on the abdominal wall as the Front Mu, or Alarm point for the organ. Front Mu points, like their Back Shu partners, occur on the thorax, abdomen, and pelvis. Ancient Chinese acupuncturists employed them to determine which organs may be impaired; they provide treatment sites as well. Neuroanatomic connections connect input from the body wall to the viscera.

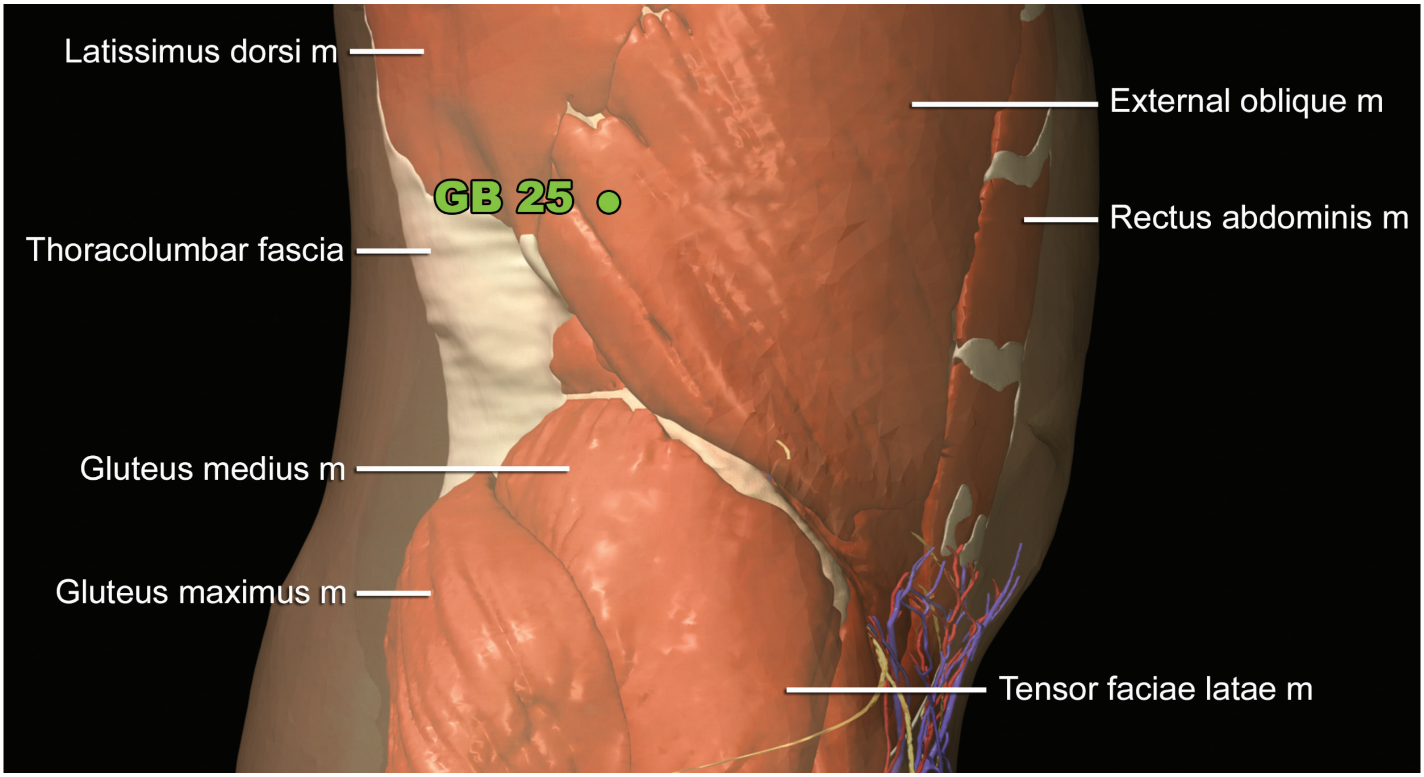

Figure 11-69. GB 25 may overlap with a myofascial trigger points in the external oblique and/or the latissimus dorsi muscle. Myofascial dysfunction in this region, when beset by trigger point pathology, may initiate somatovisceral responses that include spontaneous belching or in some cases projectile vomiting.[14] The muscles in this region, i.e., the latissimus dorsi and the external oblique together form an "unbroken sheet of muscle" as shown in this muscle layer and in the cross section of Figure 11-70.

neuromodulation and relaxation of compressive soft tissues.

Coupled with BL 23 and BL 52, GB 25 provides a dorsal and lateral input around the trunk to influence those spinal segments feeding the kidney. Its influence on genitourinary conditions springs from the proximity of GB 25 to intercostal, subcostal, ilioinguinal, and iliohypogastric nerves via spinal segmental overlap. This justifies the inclusion of GB 25 and neighboring points for the treatment of renal colic, as well as for postoperative pain following kidney surgery, and chronic pelvic pain.[11]

Expanding neuromodulation of the ilioinguinal and iliohypogastric nerves to include the genitofemoral, hypogastric, sacral, and tibial nerves as well as trigger points provides a comprehensive neuroanatomic intervention for both pelvic pain and coccygodynia.

Front Mu points such as GB 25 (along with Back Shu points such as BL 23) links the soma to the viscera by means of reflexes. These have been described to include viscerocutaneous and cutaneovisceral reflexes, though a myofascial contribution most certainly participates as well. Afferent information from the body wall (soma) converges with that from internal organs (viscera) in the dorsal horn of the spinal cord. From here, some neural signals ascend to the brain while others reflex to the viscera or soma, respectively, thereby adjoining neural activity from the body wall to that of internal structures.

GB 25 activates afferents along the T12 dermatome.[12] The kidney receives its sympathetic innervation from the T10 to L2 spinal cord segments. BL 23, the Back Shu point for the kidney, is situated along the L2 dermatome.[13] Chronic nociceptive bombardment of spinal cord segments by dint of afferent input from a dysfunctional organ such as the kidney may provoke myofascial dysfunction and cutaneous hypersensitivity at GB 25 and BL 23. Interneurons within the spinal cord mediate neuronal crosstalk from the visceral to the somatic neural pathways. Thus, tenderness to palpation discovered at the Front Mu and Back Shu points indicates associated organ disruption, soft tissue pathology, or both.

Vessels

- **Subcostal artery:** Derived from the internal thoracic arteries, the subcostal artery supplies the muscles of the anterolateral abdominal wall.
- **Subcostal vein:** Empties into the azygous venous system that drains into the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Kidney problems:** renal colic, postoperative pain relief in kidney recipients,[3] other kidney related pain: GB 25, BL 23, BL 52, GV 4, KI 3, KI 7.
- **Constipation:** GB 25, ST 25, SP 14, ST 36.
- **Lumbar and lateral costal pain:** GB 25, GB 22, and GB 23 (affecting trigger points in the latissimus dorsi muscle).

Figure 11-70. This cross section depicts the structures influenced by GB 25 needling. Direct effects include deactivation of trigger points in the external oblique or latissimus dorsi muscles. Spinal segmental influences impact the kidneys as well as intestinal function, inseparable due to overlapping spinal segmental nerve supply. Note the presence of intestines at this level, alongside the kidneys.

GB 26

Dai Mai "Belt Vessel", "Girdling Vessel"

On the mid-axillary line, cranial to the iliac crest, level with the umbilicus. Directly distal and caudal to the free end of the 11th rib and LR 13. The free end of the 11th rib typically lands at or near the mid-axillary line.

Muscles

- **External oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **Internal oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **Transverse abdominal muscle:** Compresses and supports the abdominal viscera. Since this is the deepest layer of the muscles of the abdominal wall, needling through this muscle may damage internal organs.

Clinical Relevance: Trigger point pathology in the lateral abdominal wall musculature at or near GB 26 and GB 27 may cause pain that focuses strongly in the ipsilateral groin and testis, up and over the abdomen toward the ipsilateral and even the contralateral subcostal margin, umbilicus, and lower abdomen, producing diagnostic enigmas and confusion.

Myofascial dysfunction in this zone can also upset neural regulation of the intestines through somatovisceral disturbances, producing diarrhea or colonic cramping.

Nerves

- **Thoracoabdominal nerves (T7-T11):** Innervate the external and internal oblique muscles and the transverses abdominal.
- **Iliohypogastric nerve (L1):** Supplies the skin over the iliac crest and in the hypogastric region. Supplies the internal oblique and transverse abdominal muscles. The iliohypogastric nerve begins at L1, though it may receive some fibers from T12.
- **Ilioinguinal nerve (L1):** Supplies the skin of the scrotum or labia majora, mons pubis, and that region of the medial thigh that is immediately adjacent. Also innervates the internal oblique and transverse abdominal muscles. See also the iliohypogastric nerve.
- **Subcostal (12th intercostal) nerve:** This large ventral ramus of the T12 nerve runs along the inferior border of the 12th rib and supplies the lowest slip of the external oblique muscle as well as the skin over the anterior superior iliac spine (ASIS) and hip. It sends a branch to the pyrimidalis muscle.

Clinical Relevance: The iliohypogastric nerve, along with the Ilioinguinal, lateral femoral cutaneous, and femoral nerves all emerge from the lateral border of the psoas major muscle; the obturator nerves proceeds from the medial border, and the genitofemoral nerve actually passes through the center of the belly of the psoas. Occasionally, the iliohypogastric and Ilioinguinal nerves will accompany the genitofemoral nerve through the belly of the muscle. As such, all three nerves are vulnerable to entrapment by the psoas. Taut bands in this muscle could lead to pain and paresthesias felt in the regions of their influence. See Figures 11-73B and 11-73C.

For all of the intercostal nerves along with this subcostal finale, fibers from the ipsilateral sympathetic trunk join the ventral ramus of each spinal nerve and proceed along the intercostal space,

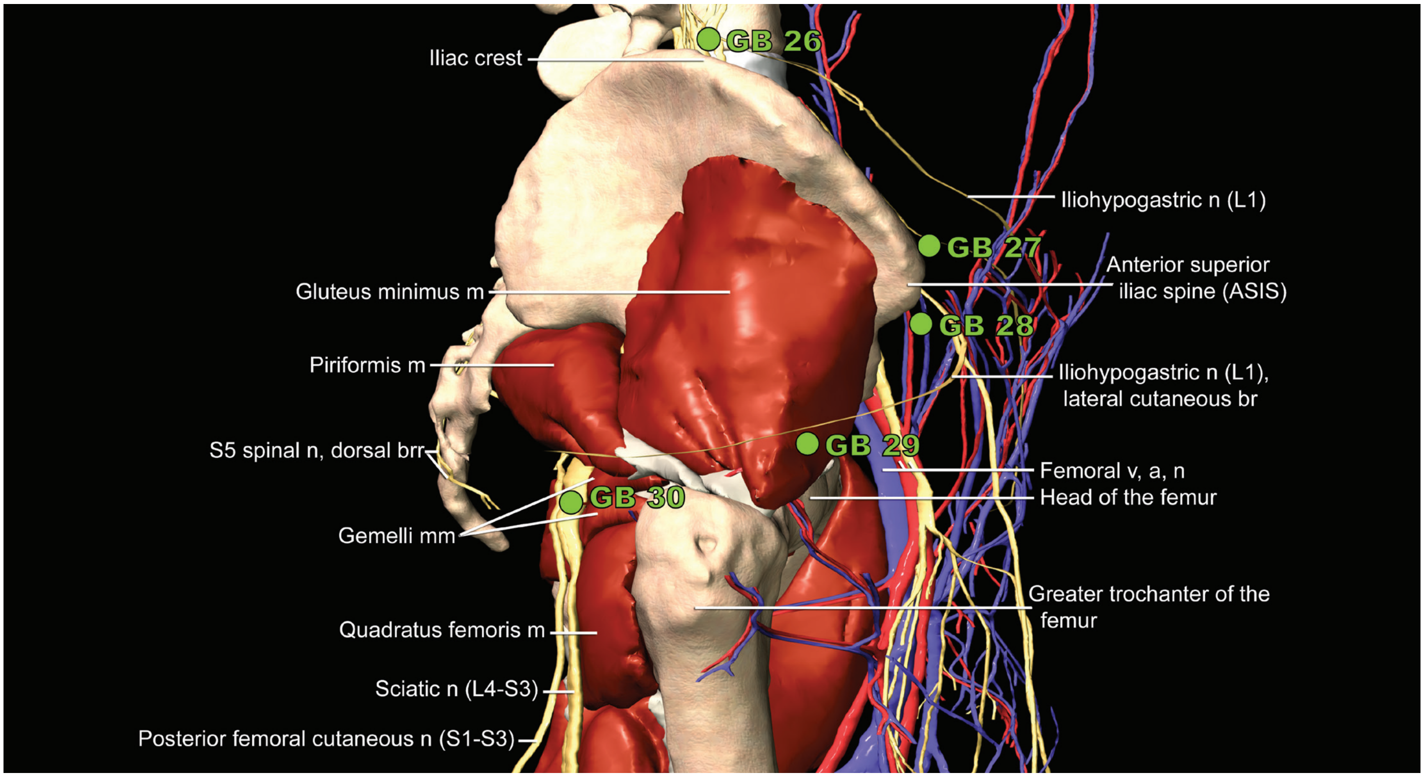

Figure 11-71. GB 26, named "Dai Mai", describes its intersection between the GB channel and the Dai Mai, or "Belt Meridian", or "Girdling Vessel". The anatomic basis for this singular vessel or "extra" channel is the iliohypogastric nerve and the subchondral neurovascular elements.

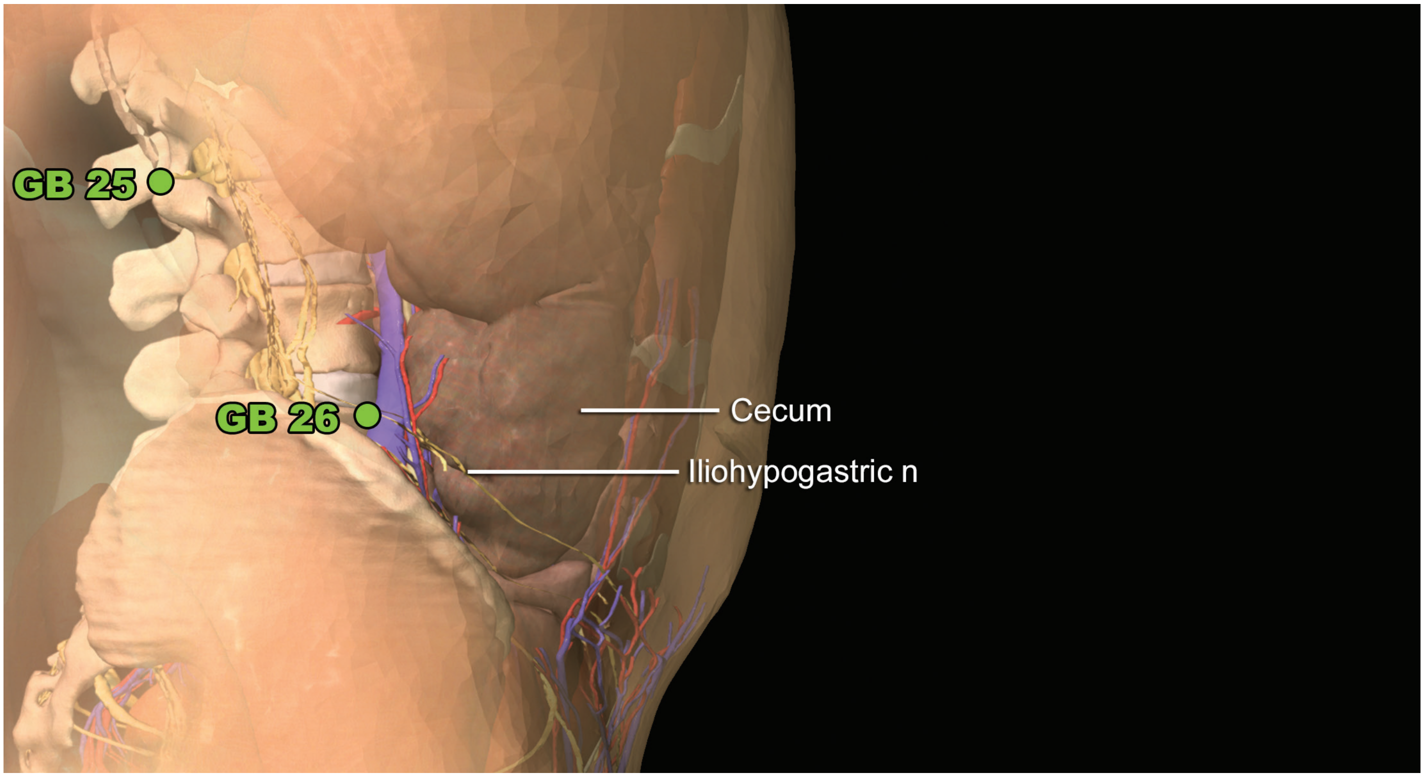
Figure 11-72. Myofascial trigger points in the lateral abdominal wall muscles (the internal and external obliques and the transversus abdominis) can lead to diarrhea, urinary irritability, pelvic pain, or groin pain. In addition to the inguinal and genital pain from these trigger points, extensions of the referred pain pattern reach upward across the abdomen to the ipsilateral and contralateral ribs, the umbilicus, and the contralateral lower abdomen. Tension in the abdominal wall musculature may entrap the ventral branches of spinal nerves; specifically, entrapment here would likely involve the ilioinguinal or iliohypogastric nerve.



GB 25
GB 26
Cecum
Iliohypogastric n

Figure 11-73A. The course of the trajectory of the GB channel follows the Iliohypogastric nerve from its origin at the thoracolumbar junction to the iliac crest. The GB line will continue this pattern as it heads toward the anterior superior iliac spine (ASIS) where at that point it associates with the lateral cutaneous branch of the iliohypogastric nerve.

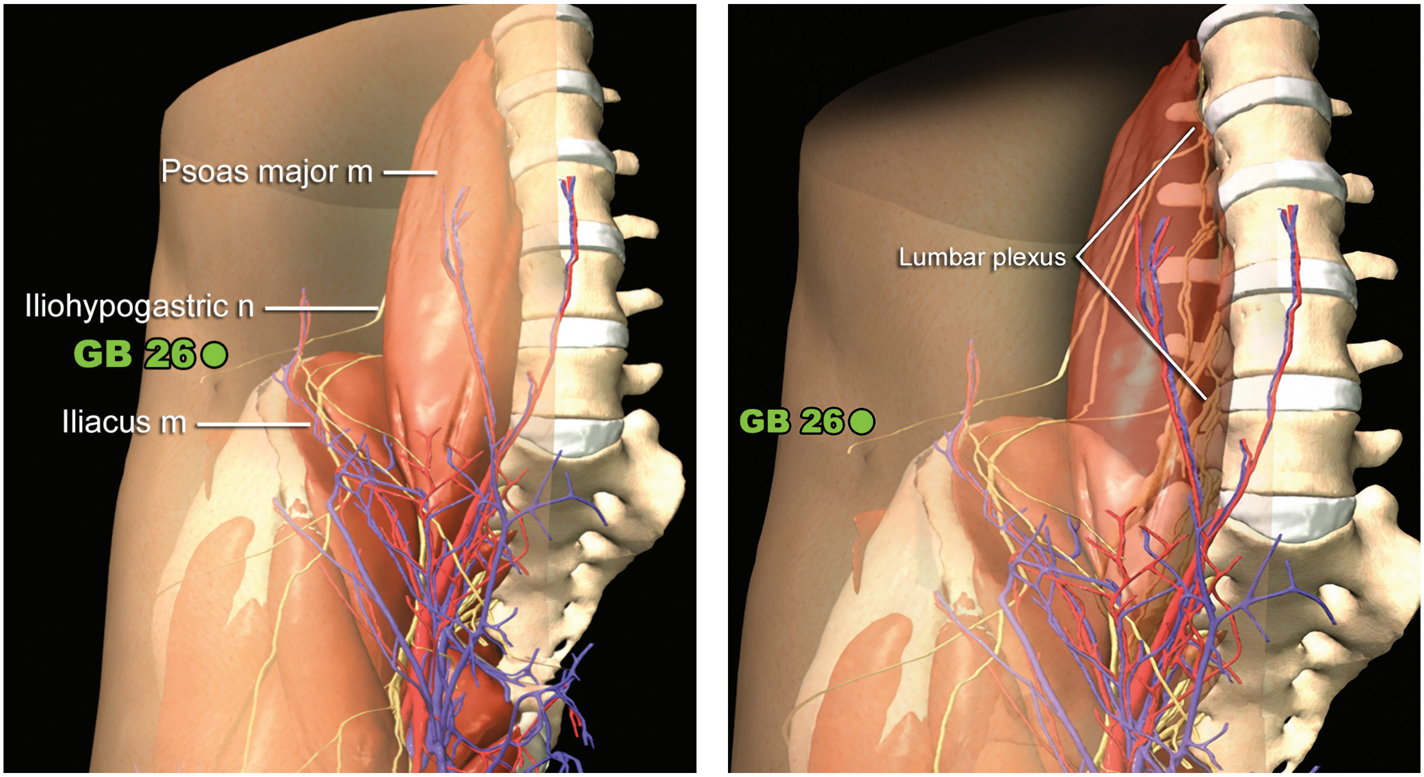


Figure 11-73B and C. The lumbar plexus, seen in 11-73C, arises from the L1 through L4 spinal nerves, with communicating branches from T12. The lumbar plexus may either reside within the posterior abdominal wall or wander through fascicles of the psoas major muscle ventral to the transverse processes of the lumbar vertebrae. The lumbar plexus gives off seven nerves, the iliohypogastric ((T12), L1), Ilioinguinal (L1), genitofemoral (L1, L2), lateral femoral cutaneous (L2, L3), obturator (L2, L3, L4), accessory obturator (L3, L4), and femoral (L2, L3, L4).

carried by the intercostal nerves, to supply blood vessels, sweat glands, and smooth muscle. The subcostal nerve communicates with the iliohypogastric nerve; together they form the neural substrate for the Dai Mai vessel, one of the eight singular vessels or "curious meridians". The subcostal nerve differs from its thoracoabdominal intercostal nerve counterparts (T7-T11 spinal nerve derivations) in terms of its larger size and the fact that its lateral cutaneous branch does not divide into anterior and posterior branches as do its compatriots. Instead, this branch, skims across the iliac crest accompanying the iliohypogastric nerve as it distributes offshoots to the skin of the groin and hip.

When it reaches the pelvis, the GB channel follows the iliac crest. It partners with the iliohypogastric nerve to the anterior superior iliac spine (ASIS) where it changes direction to backtrack to the buttocks. The Dai Mai channel, from which this point derives its name, constitutes one of the eight singular distribution vessels, otherwise defined as the "extraordinary channels" or "curious meridians". In addition to Dai Mai, the eight singular vessels include Du Mai (Governing Vessel), Ren Mai (Conception Vessel), Chong Mai (Thoroughfare Vessel), Yang Wei Mai (Yang Linking Vessel), Yin Wei Mai (Yin Linking Vessel), Yang Qiao Mai (Yang Heel Vessel) and Yin Qiao Mai (Yin Heel Vessel). Although many mistakenly view these vessels as having metaphorical, mysterious energy-based origins and difficult-to-identify trajectories, the eight singular vessels actually embody tangible neurovascular passageways. They differ from the twelve main, or principal, channels in that they have unique, or singular, aspects. Sometimes these vessels exist as a sole structure (e.g., the aorta, vena cava, or venous sinus network) which qualifies them as a "singular" vessel. Or, if they exist in a bilateral pair, their nature differs from others like them, as in the case of the subchondral vessels and nerves being set apart anatomically and functionally from their intercostal neighbors. That is, The subcostal nerve is "singular" or unique, in that it does not live between the ribs as its intercostal partners do; it is also larger and often communicates with the L1 nerve.

The term "Belt Vessel" or "Girdling Vessel" connotes a belt or sash draped loosely around the waist and hips. Figure 11-71 shows the iliohypogastric nerve and how it defines this portion of the GB channel and relates to the Dai Mai vessel. The region supplied by the T12-L1 nerves extends to the inguinal, genital, and buttock region, overlapping tightly with sphere of influence attributed to the Dai Mai vessel.[3]

In the 1940s and 1950s, Penn-Gaskell Skillern published papers on the treatment of a spectrum of autonomic and visceral dysfunctions by means of neuromodulating cutaneosympathetic and cutaneovisceral reflexes by stimulating points in the skin or blocking nerves with local anesthetic. Although his terminology differed, the sites he stimulated coincide with acupuncture points. Treatments performed at GB 26 alleviated the following conditions: "lumbar plexus neuralgia; spasm of appendix and colon with constipation; tympanites (with subsequent belching or passage of flatus); spasm of internal vesical sphincter and prostatism; spasm of internal rectal sphincter; dysmenorrhea and vasospastic menopausal disturbances; nervous fatigue."[4]

Skillern's description of the etiopathogenesis of these disturbances proceeds as follows: "Obscuring of the parasympathetic by stimulation of the sympathetic system so alters the physiology as to give rise to pathologic symptoms and signs from whatever part of the autonomic nervous system that may be involved…

Figure 11-74. The three-ply construction of the abdominal wall appears clearly in this cross section, deep and adjacent to GB 26.

It seems as though, once inaugurated, proprioceptive muscular stimuli are liable to set up a vicious circle in maintaining episodes of pain in these various neuralgias until the somatic afferent limb of the reflex arc is blocked or the muscle infiltrated with procaine directly. At the same time nociceptive bombardment of the sensorium via the spinothalamic tract is held in check.…The goal is to shrink the perimeter of these "echo" pains, etc., from intersegmental to segmental to the central focus point, leaving stranded either pain alone or a definite pathologic lesion (e.g., antral polyp) which is causing the pain."

Vessels

- **Subcostal artery:** Derived from the internal thoracic arteries, the subcostal artery supplies the muscles of the anterolateral abdominal wall.
- **Subcostal vein:** Empties into the azygous venous system that drains into the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Pain that radiates in a belt-like pattern from the lumbar region to the front of the body:** GB 26, CV 2, BL 25.
- **Gynecologic and menstrual disorders:** GB 26, SP 6, SP 10, BL 23, LI 4.
- **Low lumbar or abdominal pain:** GB 26, GB 25, BL 23, BL 26, palpate for trigger point involvement and treat accordingly.
- **Sense of heaviness deep in pelvis with cold buttocks:** GB 26, GB 28, LR 13, CV 4, GB 41, TH 5.
- **Pain or nerve injury after autologous bone harvesting:**[1] GB 26, GB 27, GB 29, BL 21-BL 23. For neuropathic pain after bone harvesting from the iliac crest, consider the possible mechanism(s) of pain (i.e., entrapment neuropathy by suture ligature strangulation or injury from intraoperative electrocautery, dissection, stretch, laceration, crush, or secondary trauma from high-speed bone saws). If neuropathic pain seems likely, the injury could involve one or more nerves because several lie in close proximity to the site of iliac crest harvesting. Potentially affected nerves include: the lateral cutaneous branch of the subcostal nerve, the lateral cutaneous branch of the iliohypogastric nerve, the lateral femoral cutaneous nerve, and the cluneal nerves.

Evidence-Based Applications

- Acupuncture at GB 26, ST 36, SP 6, and bilateral auricular Shen-Men with 40 minutes of electrostimulation added produced an **analgesic effect** equivalent to 30 mg pentazocine, as well as a net **increase of vital capacity** that pentazocine did not provide.[2]

GB 27

Wu Shu “Fifth Pivot”

On the abdomen, just medial to the anterior superior iliac spine, in a depression approximately 3 cun caudal to the umbilicus.

Muscles

- **External oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **Internal oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **Transverse abdominal muscle:** Compresses and supports the abdominal viscera. Since this is the deepest layer of the muscles of the abdominal wall, needling through this muscle may damage internal organs.
- **Iliacus muscle:** Lies lateral to the inferior part of the psoas major muscle; it then joins with the psoas to become the iliopsoas muscle, the main flexor of the thigh. It also assists the standing individual maintain an erect posture.

Clinical Relevance: Trigger point pathology in the lateral abdominal wall musculature at or near GB 26 and GB 27 may cause pain that focuses strongly in the ipsilateral groin and testis, up and over the abdomen toward the ipsilateral and even the contralateral subcostal margin, umbilicus, and lower abdomen, producing diagnostic enigmas and confusion.

Myofascial dysfunction in this zone can also upset neural regulation of the intestines through somatovisceral disturbances, producing diarrhea or colonic cramping.

Myofascial pathology in the iliacus muscle (at GB 27 and GB 28) refers pain to the proximal cranial thigh and ipsilateral paraspinal lumbar region and buttock. Note the depth at which the iliacus sits in the pelvis as seen in cross section, Figure 11-77. Safe treatment argues for non-needling techniques for iliacus trigger points.

Nerves

- **Thoracoabdominal nerves (T7-T11):** Innervate the external and internal oblique muscles and the transverses abdominal.
- **Iliohypogastric nerve (L1):** Supplies the skin over the iliac crest and in the hypogastric region. Supplies the internal oblique and transverse abdominal muscles. The iliohypogastric nerve begins at L1, though it may receive some fibers from T12.
- **Ilioinguinal nerve (L1):** This mixed nerve supplies the skin of the scrotum or labia majora, mons pubis, and that region of the medial thigh that is immediately adjacent. Also innervates the internal oblique and transverse abdominal muscles. See also the iliohypogastric nerve.
- **Subcostal (12th intercostal) nerve:** This large ventral ramus of the T12 nerve runs along the inferior border of the 12th rib and supplies the lowest slip of the external oblique muscle as well as the skin over the anterior superior iliac spine (ASIS) and hip. It sends a branch to the pyrimidalis muscle.
- **Spinal nerves (L2, L3):** Supply the iliacus muscle.

Clinical Relevance: The iliohypogastric nerve, along with the Ilioinguinal, lateral femoral cutaneous, and femoral nerves all emerge from the lateral border of the psoas major muscle; the obturator nerves proceeds from the medial border, and the genitofemoral nerve actually passes through the center of the belly of the psoas. Occasionally, the iliohypogastric and Ilioinguinal nerves will accompany the genitofemoral nerve through the belly of the muscle. As such, all three nerves are vulnerable to entrapment by the psoas. Taut bands in this muscle could lead to pain and paresthesias felt in the regions of their influence. Review Figures 11-73B and 11-73C.

At the pelvis, the GB channel follows the iliac crest. It follows the iliohypogastric nerve to the anterior superior iliac spine (ASIS) where it changes direction to backtrack to the buttocks. GB 27 and GB 28 land along this ventral arc.

For the subcostal nerve as well as the eleven intercostals, nerve fibers from the ipsilateral sympathetic trunk join the ventral ramus of each spinal nerve. These autonomic fibers supply blood vessels, sweat glands, and smooth muscle. The subcostal nerve communicates with the iliohypogastric nerve; together they form the neural substrate for the Dai Mai vessel, more fully described in the previous point section for GB 26. The subcostal nerve differs from its thoracoabdominal intercostal nerve partners (from T7-T11) in terms of its larger size and the fact that its lateral cutaneous branch does not divide into anterior and

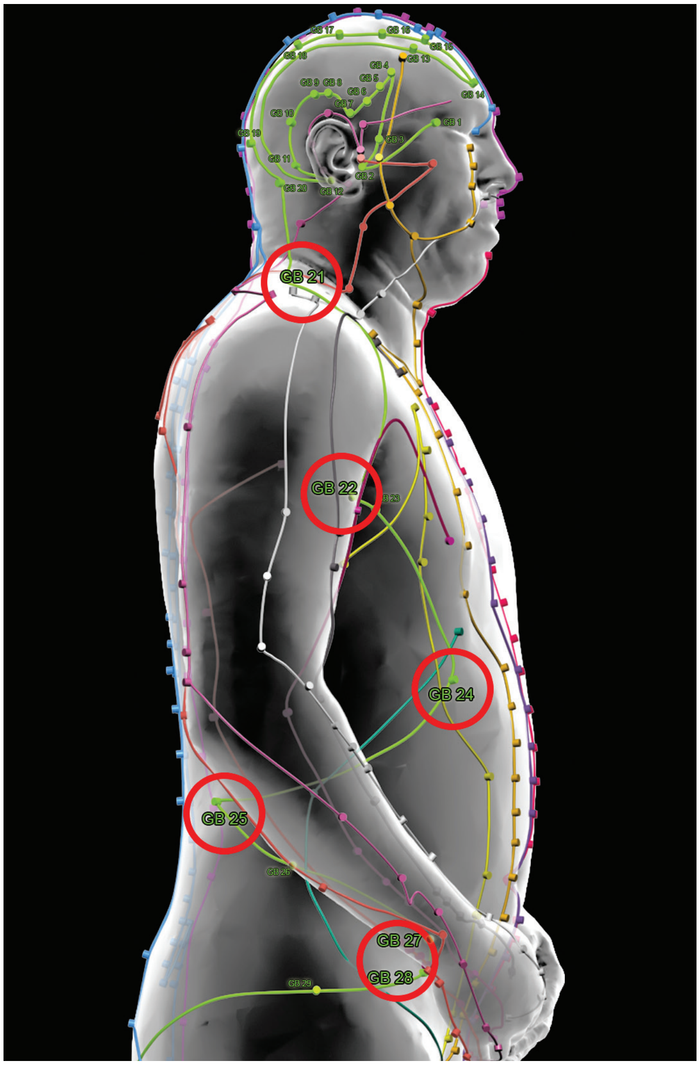

Figure 11-75. The nature of the GB line is to switch direction. From shoulder to hip, it does so five times. As the “Fifth Pivot”, GB 27 signals the final trajectory change before the channel embarks onto the pelvic limb.

posterior branches as do its compatriots. Instead, this branch, larger in size than the lateral cutaneous branches of the other lower intercostal nerves, instead passes over the iliac crest alongside the iliohypogastric nerve to distribute to the skin of the groin and hip.

The iliohypogastric nerve, one of the more caudal thoracoabdominal nerves, is susceptible to injury from surgical procedures to the lower abdomen or inguinal canal. Surgeries with such incisions may include hysterectomy, inguinal herniorrhaphy, and appendectomy. The nerves can be damaged when a suture passes around the nerve and it becomes bundled into the fascial repair. Scar tissue or neuroma formation can entrap the nerves postoperatively. Athletic injuries that traumatize or tear the lower abdominal muscles and fascia may similarly place traction on the nerve. Pregnancy can stretch the nerve as well. Figure 11-77. In addition to the effects of GB 27 on the iliohypogastric nerve, GB 27 addresses attachment trigger points on the abdominal wall. Myofascial pathology in this multilayer structure may refer pain to the groin, bladder, or pelvis as a whole. It may also invoke autonomic dysregulation in digestive and genitourinary organs. Note the location of the iliacus muscle compared to those of the abdominal wall. Trigger points in the iliacus or psoas lie largely out of reach of dry needling. Instead, opt for massage, soft tissue manual therapy, laser therapy, and/or stretching to address restriction and pain.

and GB 28 may improve nerve function, reduce pain, relieve tenderness to palpation, and benefit sensation.

Procedures that may injure the ilioinguinal nerve include Pfannenstiel incisions, incisions for iliac crest harvesting, appendectomy, inguinal herniorrhaphy, inguinal lymph node biopsy, femoral catheter placement, orchiectomy, total abdominal hysterectomy, and abdominoplasty.[4] Hockey players may tear the lower external oblique aponeurosis and injure the ilioinguinal nerve. Again, physical medicine approaches such as acupuncture may improve and normalize nerve function, which includes pain and tenderness with pressure where the nerve exits the inguinal canal as well as loss of sensation.

The variability in spinal nerve origin for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy. Conversely, issues related to pain or dysfunction of somatic or visceral tissues served by the T12-L2 spinal segments may benefit from neuromodulation applied to GB 26, GB 27, and GB 28.

The multiplicity of nerves supplying this region speaks to the multifaceted effects of GB 27 and GB 28. Many of the nerves reflex to pelvic organs and genitourinary function through spinal segmental overlap of somatic and sympathetic pathways. The lumbar plexus, comprised of the ventral rami of L1 through L4 spinal nerves and accompanied by a branch of the T12 spinal nerve ventral ramus, forms several of the nerves that supply both GB 27 and GB 28. These include the: iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.[5] The jobs these nerves do in terms of communicating between the soma and viscera along with supplying sensation, motor function, and proprioception to muscles of the pelvis and lower limb, make GB 27, like its neighbor GB 28, a neural traffic highway ferrying signals up and down, in and out.

Vessels

- **Superficial circumflex iliac artery:** Arises from the femoral artery and courses along the inguinal ligament. Supplies the skin and subcutaneous tissue over the inferior portion of the anterolateral abdominal wall.
- **Deep circumflex iliac artery:** Arises from the external iliac artery, runs parallel to the inguinal ligament along the deep part of the anterior abdominal wall. Supplies the iliacus muscle and the inferior portion of the anterolateral abdominal wall.

Clinical Relevance: Entrapment of abdominal wall nerves after surgery or trauma likely injures vessels as well. Acupuncture, massage, and laser therapy can restore circulatory health and thereby facilitate recovery.

Indications and Potential Point Combinations

- **Reproductive system or pelvic problems:** Pain, leukorrhea, endometritis, epididymitis, orchitis, pain in groin or thigh, hernia pain: GB 27, GB 26, ST 29, ST 30, CV 2, SP 6.
- **Pain that radiates in a belt-like pattern from the lumbar region to the front of the body:** GB 27, GB 26, CV 2, BL 25.
- **Failed back syndrome from iliopsoas myofascial dysfunction:**[1] GB 27, GB 28, other trigger points as found that participate in the pain problem and functional restrictions.
- **Gynecologic and menstrual disorders:** GB 27, SP 6, SP 10, BL 23, LI 4.
- **Lower abdominal pain:** GB 27, GB 25, BL 23, BL 26, palpate for trigger point involvement and treat accordingly.
- **Inguinal neuralgia involving the iliohypogastric nerve:**[2] GB 27, GB 28, SP 13, ST 29, KI 11, CV 2.
- **Sense of heaviness deep in pelvis with cold buttocks:** GB 27, GB 26, GB 28, LR 13, CV 4, GB 41, TH 5.
- **Paraspinal lumbar pain and/or cranial midline proximal thigh pain:** GB 27, GB 28, ST 31, KI 16.
- **Pain or nerve injury after autologous bone harvesting:**[3] GB 27, GB 26, GB 29, BL 21-BL 23. For neuropathic pain after bone harvesting from the iliac crest, consider mechanism of pain (i.e., entrapment neuropathy by suture ligature strangulation or injury from intraoperative electrocautery, dissection, stretch, laceration, crush, or secondary trauma from high-speed bone saws). If neuropathic pain seems likely, the injury could involve one or more nerves because several lie in close proximity to the site of iliac crest harvesting. Potentially affected nerves include: the lateral cutaneous branch of the subcostal nerve, the lateral cutaneous branch of the iliohypogastric nerve, the lateral femoral cutaneous nerve, and the cluneal nerves.

Muscles

- **External oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **Internal oblique muscle:** Supports and compresses the abdominal viscera. Flexes and rotates the trunk.
- **Transverse abdominal muscle:** Compresses and supports the abdominal viscera. Since this is the deepest layer of the muscles of the abdominal wall, needling through this muscle may damage internal organs.
- **Iliacus/Iliopsoas muscle:** Lies lateral to the inferior part of the psoas major muscle; it then joins with the psoas to become the iliopsoas muscle, the main flexor of the thigh. It also assists the standing individual maintain an erect posture.
- **Sartorius muscle:** Attaches to the ASIS and the notch below it. It flexus, abducts, and laterally rotates the thigh at the hip. It also flexes the knee, allowing the individual to sit cross-legged.

Clinical Relevance: Trigger point pathology in the lateral abdominal wall musculature at or near GB 26 through GB 28 may cause pain that focuses strongly in the ipsilateral groin and testis, up and over the abdomen toward the ipsilateral and even the contralateral subcostal margin, umbilicus, and lower abdomen, producing diagnostic enigmas and confusion. Myofascial dysfunction in this zone can also upset neural regulation of the intestines through somatovisceral disturbances, producing diarrhea or colonic cramping.

An iliopsoas myofascial trigger point in the vicinity of GB 27 and GB 28 typically refers pain to the proximal cranial thigh and ipsilateral paraspinal lumbar region and buttock. Travell and Simons’ dubbed the iliopsoas combined muscle “the hidden prankster” in that this strong hip and lumbar flexor can upset upright posture. In so doing, it cultivates trigger points in the hamstring and gluteal groups, erector spinae, and caudal cervical musculature.

The sartorius muscle, known in trigger point terms as the “surreptitious accomplice”, earned its nickname due to the finding that trigger points rarely exist in this muscle alone. Rather, they develop as a consequence of myofascial dysfunction in other muscles comprising its functional unit.

Nerves

- **Thoracoabdominal nerves (T7-T11):** Innervate the external and internal oblique muscles and the transverses abdominal.
- **Iliohypogastric nerve (L1):** Supplies the skin over the iliac crest and in the hypogastric region. Supplies the internal oblique and transverse abdominal muscles. The iliohypogastric nerve begins at L1, though it may receive some fibers from T12.
- **Ilioinguinal nerve (L1):** Supplies the skin of the scrotum or labia majora, mons pubis, and that region of the medial thigh that is immediately adjacent. Also innervates the internal oblique and transverse abdominal muscles. See also the iliohypogastric nerve.
- **Subcostal (12th intercostal) nerve:** This large ventral ramus of the T12 nerve runs along the inferior border of the 12th rib and supplies the lowest slip of the external oblique muscle as well as the skin over the anterior superior iliac spine (ASIS) and hip. It sends a branch to the pyrimidalis muscle.

Figure 11-78. The ASIS, a “pivot point” for the GB line (see description for GB 27, itself named “Fifth Point”), connects the lower abdomen to the pelvis. In this way, GB 28 provides a “Linking Path” between the trunk and limb.

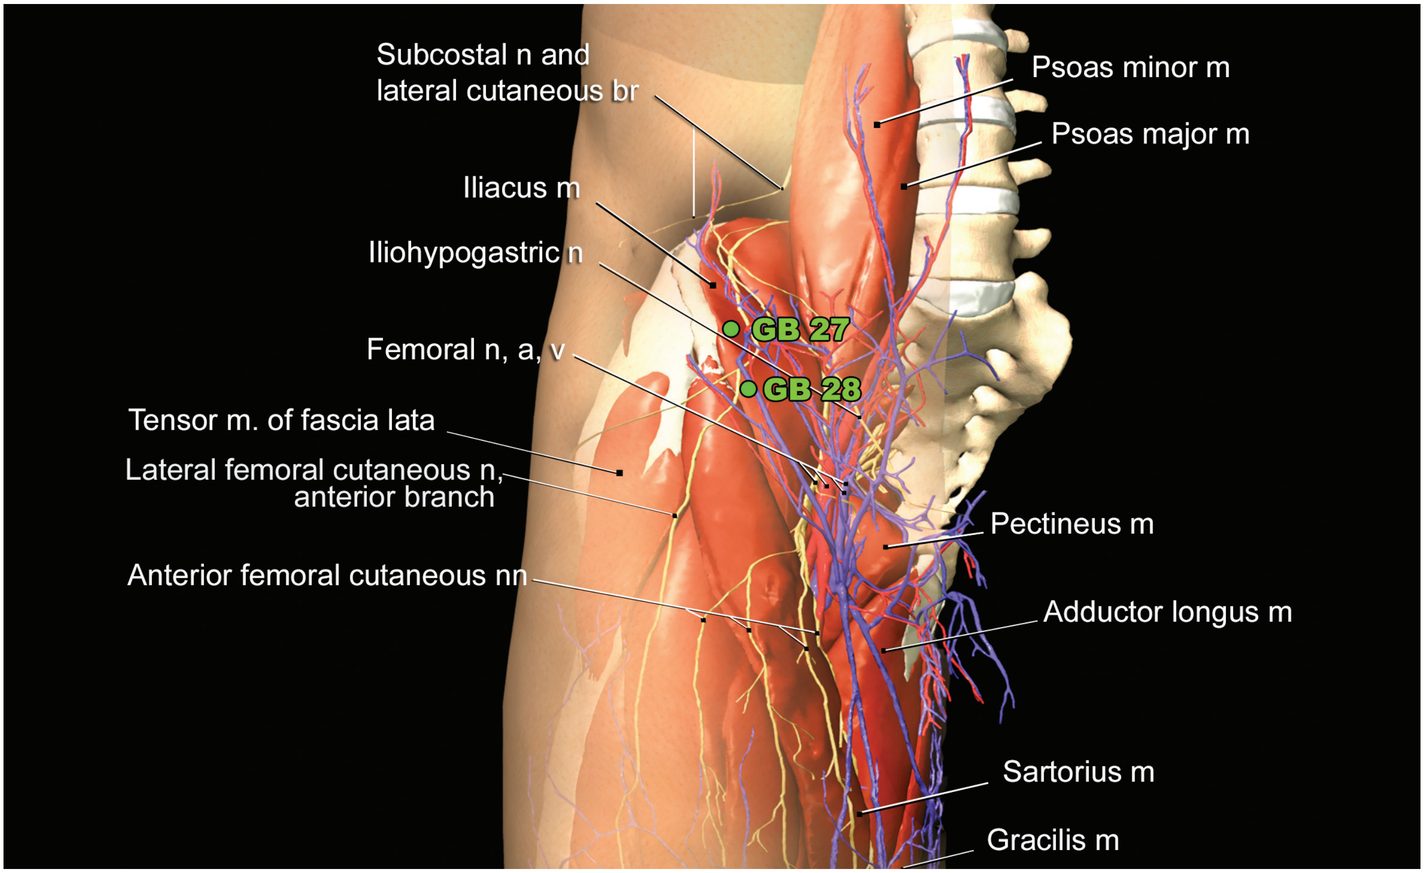

Figure 11-79. The sartorius and iliacus muscles near GB 28 can harbor attachment trigger points. Myofascial pathology in the iliacus muscle (at GB 27 and GB 28) refers pain to the proximal cranial (anterior) thigh and ipsilateral paraspinal lumbar region and buttock. Sartorius trigger points produce pain and paresthesias in the cranial (anterior) thigh along the muscle's course. See also Figure 11-76 to view the entire length of the cranial thigh. Note the branching of the lateral femoral cutaneous nerve into anterior (cranial) and posterior (caudal) components at GB 28 in this image.

- **Spinal nerves (L2, L3):** Supply the iliacus muscle.
- **Femoral nerve (L2-L3):** Innervates the sartorius muscle.
- **Lateral femoral cutaneous nerve (L2-L3):** Supplies the skin on the lateral thigh. (See Figures 11-79 and 11-76).

Clinical Relevance: The iliohypogastric nerve, along with the Ilioinguinal, lateral femoral cutaneous, and femoral nerves all emerge from the lateral border of the psoas major muscle; the obturator nerves proceeds from the medial border, and the genitofemoral nerve actually passes through the center of the belly of the psoas. Occasionally, the iliohypogastric and Ilioinguinal nerves will accompany the genitofemoral nerve through the belly of the muscle. As such, all three nerves are vulnerable to entrapment by the psoas. Taut bands in this muscle could lead to pain and paresthesias felt in the regions of their influence.

At the pelvis, the GB channel follows the iliac crest. The GB line then courses with the iliohypogastric nerve to the anterior superior iliac spine (ASIS) where it changes direction to backtrack to the buttocks. GB 27 and GB 28 land along this ventral arc.

For the subcostal nerve as well as the eleven intercostal nerves, fibers from the ipsilateral sympathetic trunk join the ventral ramus of each spinal nerve. These autonomic fibers supply blood vessels, sweat glands, and smooth muscle. The subcostal nerve communicates with the iliohypogastric nerve; together they form the neural substrate for the Dai Mai vessel, more fully described in the point section for GB 26. The subcostal nerve differs from its thoracoabdominal intercostal nerve partners (from T7-T11) in terms of its larger size and the fact that its lateral cutaneous branch does not divide into anterior and posterior branches as do its compatriots. Instead, this branch, larger in size than the lateral cutaneous branches of the other lower intercostal nerves, passes over the iliac crest alongside the iliohypogastric nerve to distribute to the skin of the groin and hip.

The iliohypogastric nerve, as one of the more caudal thoracoabdominal nerves, is susceptible to injury from surgical procedures to the lower abdomen or inguinal canal. Surgeries with such incisions may include hysterectomy, inguinal herniorrhaphy, and appendectomy. The nerves can be damaged when a suture passes around the nerve and it becomes bundled into the fascial repair. Scar tissue or neuroma formation can entrap the nerves postoperatively. Athletic injuries that traumatize or tear the lower abdominal muscles and fascia may similarly place traction on the nerve. Pregnancy can stretch the nerve as well. Acupuncture and related techniques in the vicinity of GB 27 and GB 28 may improve nerve function, reduce pain, relieve tenderness to palpation, and benefit sensation.

Procedures that may injure the ilioinguinal nerve include Pfannenstiel incisions, incisions for iliac crest harvesting, appendectomy, inguinal herniorrhaphy, inguinal lymph node biopsy, femoral catheter placement, orchiectomy, total abdominal hysterectomy, and abdominoplasty.[4]

Hockey players may tear the lower external oblique aponeurosis and injure the ilioinguinal nerve. Again, physical medicine approaches such as acupuncture may improve and normalize nerve function, which includes pain and tenderness with pressure where the nerve exits the inguinal canal as well as loss of sensation.

The variability in spinal nerve origin for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy. From a neuromodulation standpoint, pain or dysfunction in regions supplied by the T12-L2 spinal segments, whether somatic or visceral, may benefit from neuromodulation applied to GB 26, GB 27, and GB 28.

The multiplicity of nerves coursing throughout section of the GB channel introduces a variety of indications for points GB 26 through GB 28. Several nerves reflex to pelvic organs and influence genitourinary function by means of convergent somatic and sympathetic pathways in the spinal cord. The lumbar plexus, comprised of the ventral rami of L1 through L4 spinal nerves and accompanied by a branch of the T12 spinal nerve ventral ramus, gives off several of the nerves that supply both GB 27 and GB 28. These include the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.[5] The jobs these nerves do in terms of communicating between the soma and viscera along with supplying sensation, motor function, and proprioception to muscles of the pelvis and lower limb make GB 28 into a neural corridor or "Linking Path" for afferent and efferent information.

"Iliacus syndrome" pertains to the set of symptoms and signs arising from entrapment of the femoral nerve at in the GB 27/GB 28 region of the groin and pelvis.[6]

The lateral femoral cutaneous nerve emerges from the lumbar plexus at the lateral border of the psoas muscle, crosses the iliacus in an oblique fashion, and travels toward the ASIS. On its way to the thigh, it migrates deep to the inguinal ligament and across the sartorius muscle, whereupon it divides into anterior and posterior branches. Communications exist between the anterior branch of the lateral femoral cutaneous nerve and the anterior cutaneous branches of the femoral nerve itself. Communicating branches may also join from the lateral femoral to the infrapatellar branch of the saphenous nerve. When this occurs, the two create what is known as the "peripatellar plexus". This anatomical adjoining justifies inclusion of ST points as well as SP points for cranial knee pain. It also suggests considering GB 27 and GB 28 as proximal points to neuromodulate contribution from the lateral femoral cutaneous nerve to knee dysfunction.

Lateral femoral cutaneous neuropathy is also known as "meralgia paresthetica", or painful thigh. Causes include avulsion fracture of the ASIS, tumor in the pelvic cavity or retroperitoneal space, traction on the nerve due to prolonged hip and trunk hyperextension, leg length discrepancy, iatrogenic procedures, prolonged standing, weight gain, and external compression by heavy belts or tight clothing. Patients experience the burning pain and paresthesias associated with neuropathy. Pressure applied to GB 27, GB 28, and/or the ASIS may worsen the problems. Hip flexion alleviates the discomfort by providing more room for the nerve. Corrective actions include education on proper body mechanics, therapeutic exercise, elimination of heavy belts and avoidance of tight clothing, weight loss, and neuromodulation that allows the iliopsoas to relax and removes myofascial restriction compressing the nerve.

The posterior branch of the lateral femoral cutaneous nerve enters the fascia lata and divides into filaments that course laterad and caudad along the thigh. Figure 11-79 illustrates the caudal course that the posterior, or caudal, branch of the lateral femoral cutaneous nerve takes. At GB 28, this branch turns toward the hip and GB 29. These caudal branch fibers supply sensation to the skin from the greater trochanter to mid-thigh, following the GB line. Observe the location of the femoral nerve within the iliacus muscle shown by Figure 11-80. While the femoral nerve may also experience entrapment where it exists the abdomen deep to the inguinal ligament in a tunnel called the "lacuna musculorum", iliacus syndrome involves compression of the nerve by dint of myofascial restriction and/or scarring. A variety of etiologies cause this problem, including iatrogenic injury during surgery, trauma to the pelvis and hip, tension or abnormal enlargement of the iliopsoas muscle following tear, hematoma, or mass, distension of the iliopsoas bursa, and pseudoaneurysm of the iliac vessels.[7]

Vessels

- **Superficial circumflex iliac artery:** Arises from the femoral artery and courses along the inguinal ligament. Supplies the skin and subcutaneous tissue over the inferior portion of the anterolateral abdominal wall.

- **Deep circumflex iliac artery:** Arises from the external iliac artery, runs parallel to the inguinal ligament along the deep part of the anterior abdominal wall. Supplies the iliacus muscle and the inferior portion of the anterolateral abdominal wall.

Clinical Relevance: Entrapment of abdominal wall nerves after surgery or trauma likely injures vessels as well. Acupuncture, massage, and laser therapy can restore circulatory health and thereby facilitate recovery.

Indications and Potential Point Combinations

- **Gynecologic and menstrual disorders:** GB 28, ST 30, SP 6, SP 10, BL 23, LI 4.

- **Reproductive system or pelvic problems:** Pain, leukorrhea, endometritis, epididymitis, orchitis, pain in groin or thigh, hernia pain: GB 28, GB 26, ST 29, ST 30, CV 2, SP 6.

- **Lower abdominal pain:** GB 28, GB 25, BL 23, BL 26, palpate for trigger point involvement and treat accordingly.

- **Pain that radiates in a belt-like pattern from the lumbar region to the front of the body:** GB 28, GB 26, CV 2, BL 25.

- **Sense of heaviness deep in pelvis with cold buttocks:** GB 28, GB 26, GB 28, LR 13, CV 4, GB 41, TH 5.

- **Pain or nerve injury after autologous bone harvesting:**[1] GB 28, GB 27, GB 26, GB 29, BL 21-BL 23. For neuropathic pain after bone harvesting from the iliac crest, consider mechanism of pain (i.e., entrapment neuropathy by suture ligature strangulation or injury from intraoperative electrocautery, dissection, stretch, laceration, crush, or secondary trauma from high-speed bone saws). If neuropathic pain seems likely, the injury could involve one or more nerves because several lie in close proximity to the site of iliac crest harvesting. Potentially affected nerves include: the lateral

GB 29

Ju Liao "Squatting Bone-Hole"

On the lateral hip, midway between the anterior superior iliac spine (ASIS) and the most prominent part of the greater trochanter. Locate with the patient in lateral recumbency with the hip slightly flexed.

Note: The Chinese term "Ju Liao" for GB 29 is the same name given to ST 3. Both refer to large palpable depressions.

Fascia

- **Fascia lata:** The strong and deep fascia of the lower limb envelops the muscles it contains like an elastic stocking. By preventing the muscles of the limb from bulging during contraction, blood returns from the limb to the heart more efficiently.
- **Iliotibial band:** The iliotibial band (ITB) constitutes a thickening of the fascia lata on the lateral aspect of the limb, originating from fibers of the gluteus maximus, gluteus medius, and tensor fasciae latae muscles. It functions in part as a tendon for these structures. The ITB attaches proximal to the knee joint into the lateral femoral condyle as well as distal to the knee into the infracondylar tubercle of the tibia. Where it attaches below the knee, it inserts onto the tibial and fibula. There, it trifurcates into three separate bands. One attaches to the lateral aspect of the patella, one to Gerdy's tubercle, and one to the fibular head and biceps femoris tendon and aponeurosis. View the extensive size of the iliotibial band in Figure 11-82. Considering its femoral and tibial mechanical connections, atypical or abnormal hip and lower limb movements could strain the ITB.

Clinical Relevance: At the knee, the ITB functions primarily as a lateral stabilizing ligament to the lateral hip and knee.[1] The ITB performs a complex series of functions that aid in knee stabilization through both flexion and extension. Iliotibial band syndrome (ITBS) is considered the second leading cause of pain in runners. It has become the most common source of lateral knee pain.[3] Female runners who develop this syndrome exhibit limb kinematics suggestive of increased stress placed on the iliotibial band. While making adjustments in posture and limb motions during exercise would aid ITBS, acupuncture, massage, and laser therapy applied to the hip, ITB, and knee insertions supports recovery as well.

Muscles

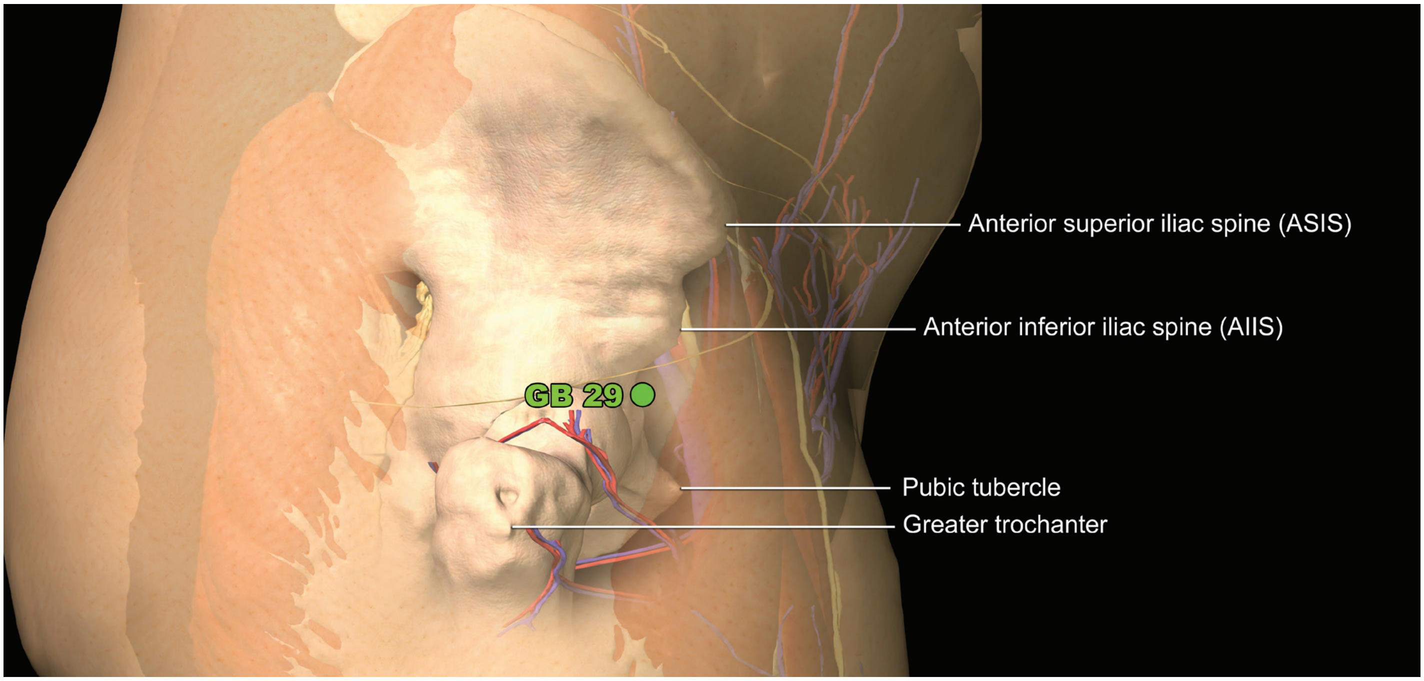
- **Tensor fasciae latae muscle:** Acts on the thigh to abduct, medially rotate, and flex it. Helps keep the knee extended and steadies the pelvis on the femur. Mainly serves to control movement of the hip by assisting the gluteus medius and minimus muscles in stabilizing the pelvis onto the femur bones.

The most posterolateral fibers, in the vicinity of GB 29, also assist in stabilizing the knee.

- **Gluteus medius muscle:** Abducts the thigh and medially rotates it. Maintains the pelvis in a level position when the individual raises the contralateral leg.
- **Gluteus minimus muscle:** Abducts the thigh and medially rotates it. Maintains the pelvis in a level position when the individual raises the contralateral leg.

Clinical Relevance: Myofascial trigger points in the tensor fasciae latae at or near GB 29 lead to a condition known as "pseudotrochanteric bursitis" which produces pain in the hip that radiates down the anterolateral thigh, occasionally reaching the knee. Differential diagnoses include true trochanteric bursitis, L4 neuropathy caused by lumbar spondylosis, iliotibial tract friction syndrome, sacroiliac arthritis, or a peripheral nerve entrapment known as meralgia paresthetica.

Dubbed the "lumbago muscle", trigger points in the gluteus



Anterior superior iliac spine (ASIS)
Anterior inferior iliac spine (AIIS)
GB 29
Pubic tubercle
Greater trochanter

Figure 11-81. GB 29, the "Squatting Bone-Hole", forms a clearly-defined cleft in the lateral aspect of the hip when the individual adopts a crouching position. With the gluteus medius and minimus removed in this image, this "scoop" appears more prominently.

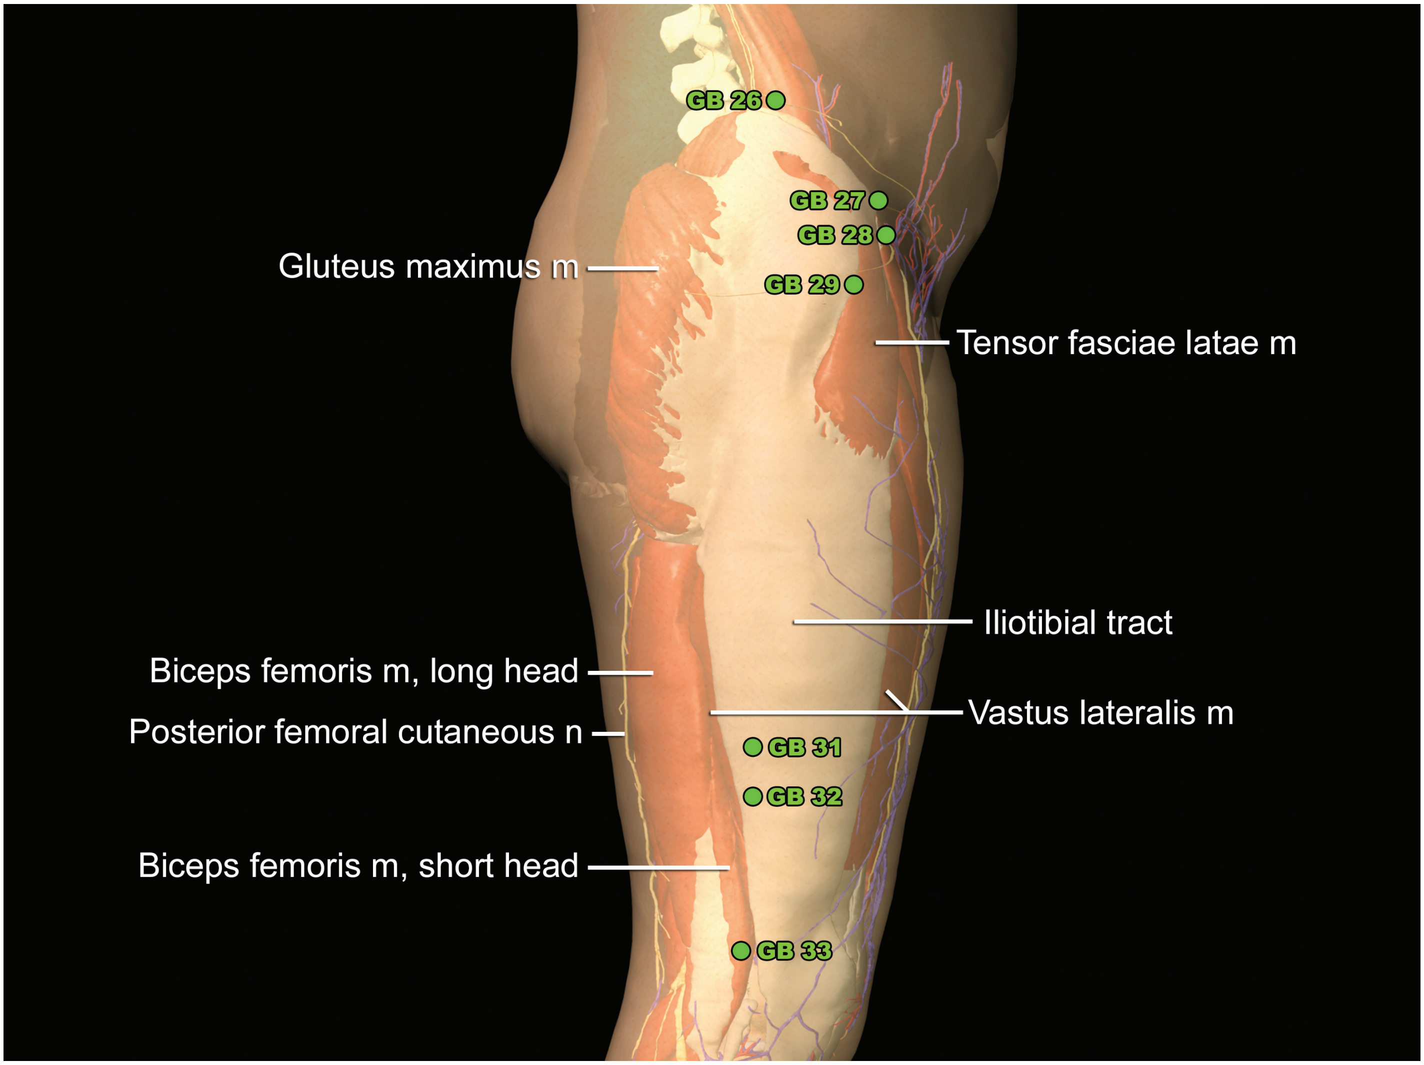


Figure 11-82. The iliotibial tract, or band, extends from the ilium to the tibia and fibula. This image depicts the relationship that several GB points share with this fascial band. This snapshot of the proximal GB channel on the limb highlights the close relationship the GB channel maintains with fascia and stabilizing yet often pain-producing connective tissue.

medius muscle refer pain to the low back.

Trigger points in the gluteus minimus muscle cause pain to radiate toward the buttock and down the leg along the GB and BL channels. This composite of pain resembles sciatic neuropathy and has earned this muscle the reputation of causing "pseudo-sciatica".

The hip abductor muscles (gluteus medius and minimus, as well as the tensor fasciae latae muscles) stabilize the pelvis during gait; they also abduct and rotate the hip joint.[4] Their close association with the ITB and mechanics of the hip joint make them vulnerable to strain and overuse. Note their size and bulk in Figure 11-84. Their appearance suggests a likelihood to harbor multiple myofascial trigger points.

Nerves

- **Superior gluteal nerve (L4, L5, S1):** Innervates the gluteus medius, gluteus minimus, and tensor fasciae latae muscles.
- **Lateral femoral cutaneous nerve (L2-L3):** Supplies the skin on the lateral thigh. (See Figures 11-79 and 11-76).

Clinical Relevance: The superior gluteal nerve exits the pelvis by way of the greater sciatic foramen, cranial to the piriformis muscle. It courses between the gluteus medius and minimus muscles.[5] It travels with the superior gluteal vessels to supply the gluteus medius, gluteus minimus, and tensor fasciae latae muscles along with the hip joint itself. Total hip arthroplasty along with other types of pelvic surgeries risk damaging the superior gluteal nerve. Up to 8% of patients undergoing total hip replacement incur injury to the superior and inferior gluteal nerves.[6] Problems resulting from this damage can severely affect patients' use of the limb and comfort; the injury can last a year or longer following hip replacement surgery. When damage to the nerve does occur, neuromodulation with laser therapy, acupuncture, and massage should follow soon thereafter. Due to the risk of infection with a recent joint implant, however, laser therapy may be preferable in this instance, in order to avoid introducing bacteria at the implant site. Following the acute postoperative period, however, local acupuncture can follow. Non-local acupuncture and carefully performed medical massage should not be a problem in the acute period, as long as good hygiene practices are maintained (hand washing, sterile needles, etc.).

The lateral femoral cutaneous nerve emerges from the lumbar

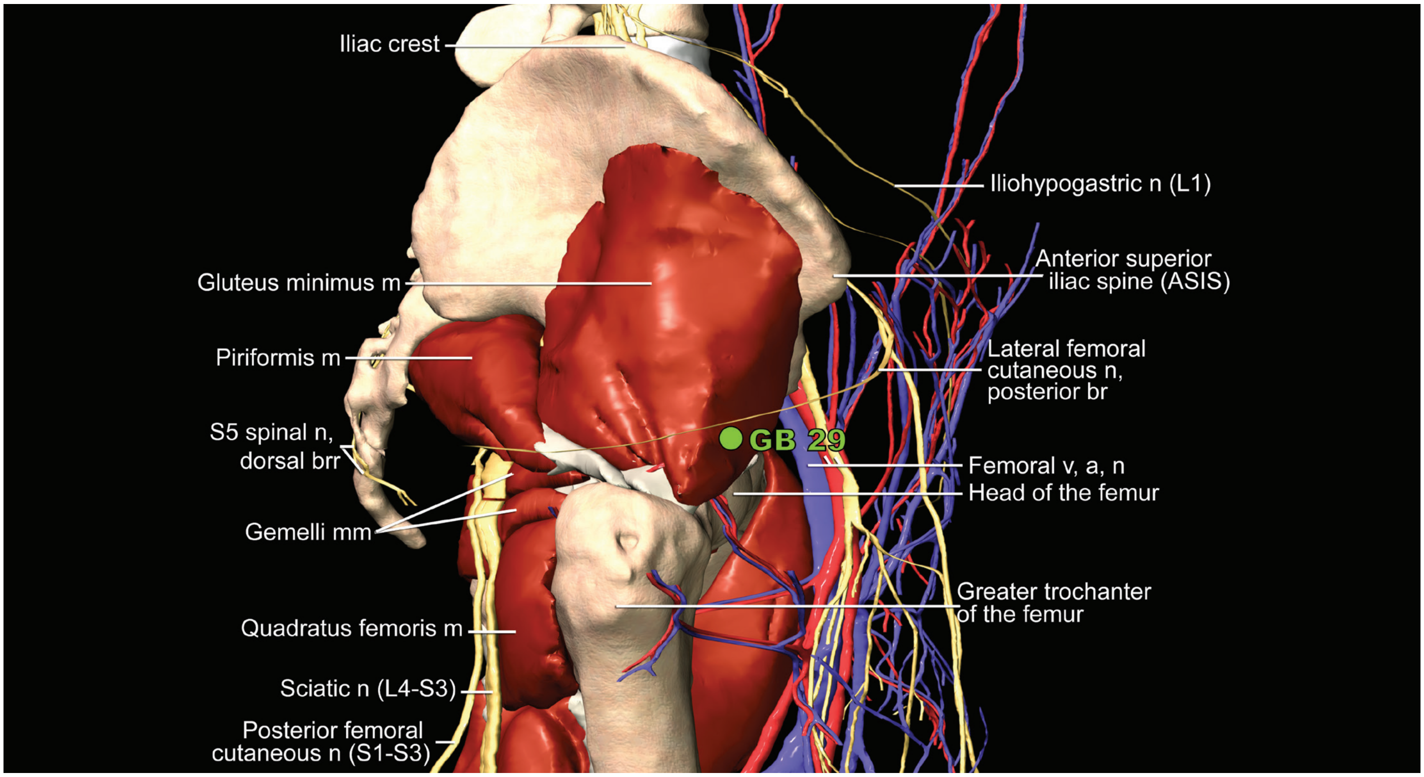

Figure 11-83. Trigger points in the gluteus minimus muscle radiate severe pain to the buttock and down the pelvic limb. Tenderness to palpation occurs at GB 30 and BL 54 as well as the lineup of points from GB 31 to GB 39 as well as BL 59. Because the intensity of discomfort mimics sciatica but does not involve the sciatic nerve, pain from gluteus minimus trigger points has been called "pseudo-sciatica". This image illustrates the depth of the gluteus minimus muscle. Locating it and its trigger points requires concerted focus on the local anatomy and deeper palpation than most other sites.

plexus at the lateral border of the psoas muscle, crosses the iliacus in an oblique fashion, and travels toward the ASIS. On its way to the thigh, it migrates deep to the inguinal ligament and across the sartorius muscle, whereupon it divides into anterior and posterior branches. Communications exist between the anterior branch of the lateral femoral cutaneous nerve and the anterior cutaneous branches of the femoral nerve itself. Communicating branches may also join from the lateral femoral to the infrapatellar branch of the saphenous nerve. When this occurs, the two create what is known as the "peripatellar plexus". This anatomical adjoining justifies inclusion of ST points as well as SP points for cranial knee pain. It also suggests considering GB 27 and GB 28 as proximal points to neuromodulate contribution from the lateral femoral cutaneous nerve to knee dysfunction.

Lateral femoral cutaneous neuropathy is also known as "meralgia paresthetica", or painful thigh. Causes include avulsion fracture of the ASIS, tumor in the pelvic cavity or retroperitoneal space, traction on the nerve due to prolonged hip and trunk hyperextension, leg length discrepancy, iatrogenic procedures, prolonged standing, weight gain, and external compression by heavy belts or tight clothing. Patients experience the burning pain and paresthesias associated with neuropathy. Pressure applied to GB 27, GB 28, and/or the ASIS may worsen the problems. Hip flexion alleviates the discomfort by providing more room for the nerve. Corrective actions include education on proper body mechanics, therapeutic exercise, elimination of heavy belts and avoidance of tight clothing, weight loss, and neuromodulation that allows the iliopsoas to relax and removes myofascial restriction compressing the nerve.

The posterior branch of the lateral femoral cutaneous nerve enters the fascia lata and divides into filaments that course laterad and caudad along the thigh. Figure 11-79 illustrates the caudal course that the posterior, or caudal, branch of the lateral femoral cutaneous nerve takes. At GB 28, this branch turns toward the hip and GB 29. These caudal branch fibers supply sensation to the skin from the greater trochanter to mid-thigh, following the GB line.

Vessels

- **Superior gluteal artery:** Deep branch runs between the gluteus medius and gluteus minimus muscles to supply these muscles and the tensor fasciae latae muscle.
- **Superior gluteal vein:** Accompanies the superior gluteal artery, draining blood from the gluteal region. A tributary of the internal iliac vein.

Clinical Relevance: The superior gluteal vessels, like the superior gluteal nerve, may undergo damage during total hip arthroplasty as well as other pelvic orthopedic and soft tissue surgeries. As with neurotrauma, laser therapy will aid in regenerating tissue and restoring function to damaged tissues.

The superior gluteal artery contributes indirectly to femoral head circulation by participating in a "periacetabular vascular ring".[7] Vessels forming this ring include the gluteal vessels proximally and circumflex femoral vessels distally. A supra-acetabular branch of the superior gluteal artery frequently forms an anastomosis with the ascending branch of the lateral femoral circumflex artery. It may also connect to the proximal deep branch of the inferior gluteal artery on the dorsal acetabulum. Thus, even when one artery loses function if injured during

surgery or trauma, others may aid in providing circulation to the joint, fostered and encouraged with laser therapy, acupuncture, and massage.

Indications and Potential Point Combinations

- **Pain in the low back, pelvis, or hip:** GB 29, GB 30, BL 54, BL 40, GB 34, BL 62, BL 23, and trigger points involved in the generation and maintenance of the pain problem.
- **Problems with hip mobility or leg strength:** GB 29, GB 30, BL 54, BL 40, other pertinent trigger points.
- **Iliotibial band syndrome:** GB 29, GB 30. Palpate for trigger points in the hip abductors and along the iliotibial band and its attachment sites. Include massage or soft tissue manipulative therapy. Osteopathic manipulative treatment for iliotibial band friction syndrome has been shown to improve with counterstrain technique.[8] Conservative measures should be investigated and given an opportunity to work before any surgical treatment attempted.

Evidence-Based Applications

- Needling GB 30, GB 34, and BL 62 for **piriformis injury syndrome** outperformed needling at GB 30, GB 29, BL 36, and GB 34 in a reportedly randomized controlled trial.[2]

GB 30

Huan Tiao "Jumping Round"

One-third the distance from the most prominent part of the greater trochanter to the sacral (sacrococcygeal) hiatus, at GV 2. Locate with the patient in lateral recumbency and with the hip slightly flexed. Review Figure 11-86 for the relationship of GB 30 to GV 2 and the greater trochanter.

Muscles

- **Gluteus maximus muscle:** Assists the thigh in lateral rotation and extends it when the thigh is flexed. Steadies the thigh and assists in standing after rising from a sitting position.
- **Short hip lateral rotator muscles: (piriformis, superior gemellus, obturator internus, inferior gemellus, and quadratus femoris):** All of the aforementioned muscles laterally rotate the thigh and steady the femoral head within the acetabulum. All except the quadratus femoris abduct the flexed thigh.

Clinical Relevance: Gait disturbances, trauma, hematoma, and trigger point pathology may precipitate piriformis syndrome by causing muscle spasm, contracture, scarring, and/or inflammation. While acupuncture at GB 30 can impact trigger points in the gluteus maximus muscle, its stronger clinical impact relates to its impact on the piriformis muscle and other short lateral rotators of the hip – the gemelli, quadratus femoris, and obturator internus muscles.

Specifically, pain emanating from myofascial dysfunction in this region arises both from the referred pain from trigger points as well as nerve entrapment from the shortened muscles shown in Figure 11-86.

Nerves

- **Inferior clunial nerves (S2, S3):** Supply the skin of the gluteal region as far as the greater trochanter.
- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.
- **Sciatic nerve (L4-S3):** Supplies all posterior thigh, leg and foot muscles, as well as the skin of the foot and most of the leg.
- **Nerve to obturator internus (L5, S1):** Supplies the superior gemellus and obturator internus muscles.
- **Nerve to quadratus femoris (L5, S1):** Supplies the quadratus femoris and inferior gemellus muscles.
- **Branches of ventral rami of S1 and S2:** Supply the piriformis muscle.

Clinical Relevance: The piriformis in particular can act as a "double devil" in its generation of pain, both because of trigger points at GB 30 and BL 30 as well as its tendency to place pressure on the sciatic nerve when the muscle enters a state of chronic contraction. Piriformis entrapment syndromes can compress nerves traveling through the greater sciatic foramen, including the superior gluteal nerve and blood vessels, the sciatic nerve, the pudendal nerve and associated vessels, the inferior gluteal nerve, the posterior femoral cutaneous nerve, and the nerves to the gemelli, obturator internus, and quadratus femoris muscles. Ongoing compression of nerves and vessels exiting the greater sciatic foramen would thus compromise sensation, motor function, and blood flow to and from the gluteal muscles, perineum, and posterior thigh and calf. Neuropathy of the aforementioned nerves would lead to pain in the buttock, inguinal region, posterior thigh, and lower limb. Sexual dysfunction may accompany the somatic complaints. Female patients may experience dyspareunia and males may complain of impotence. Constipation may worsen trigger point pain from the piriformis muscle, when hard feces press against the muscle causing a perception of rectal pain.

Entrapment neuropathy goes either un-recognized or under-recognized in both human and veterinary medicine. This cause of pain and functional impairment produces either acute or chronic injury to peripheral nerves. Symptoms and signs may overlap with other neurogenic problems, posing further challenges to accurate diagnosis. Compression, entrapment, and stretching injure nerves most commonly where space becomes constrained anatomically or functionally (e.g., secondary to myofascial restriction).

Sciatic entrapment neuropathy more commonly damages the fibular division. The fibular component of the sciatic nerve, in contrast to its tibial partner, occupies a more superficial position with less supportive connective tissue to protect it from compression. In addition, while the positions of both are fixed at the sciatic foramen, the fibular portion is also tethered at the fibular head. Thus, the fibular nerve has less opportunity for mobility. Sciatic neuropathy mimics distal common fibular neuropathy in that both may manifest as foot drop secondary to loss of nerve supply to the anterior (cranial) tibialis muscle.

The most common cause of sciatic neuropathy occurs when the surgeon either overstretches or directly traumatizes the nerve during total hip arthroplasty. Piriformis muscle syndrome, described above, entraps the sciatic as well.

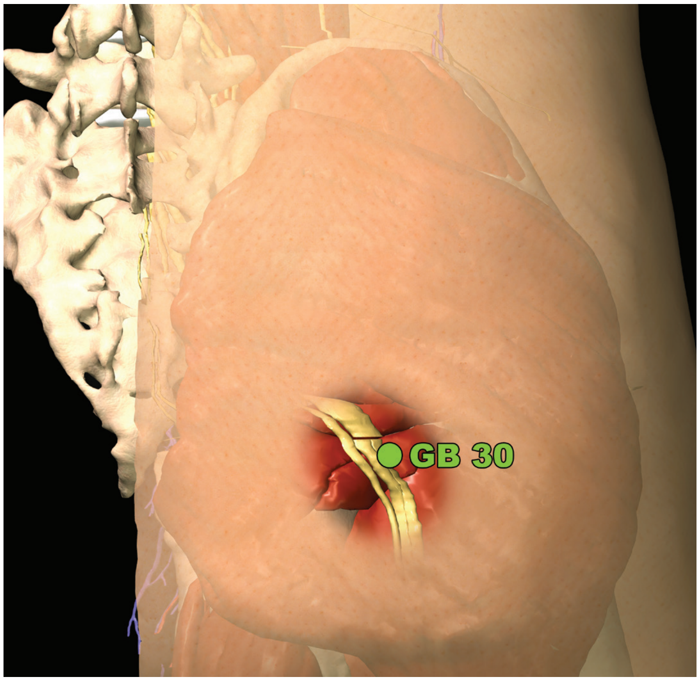

Figure 11-85. The gluteus maximus muscle spreads across nearly the entire buttock. This window through the skin and muscle exposes the nearby sciatic nerve at GB 30. The point's name, "Jumping Round", speaks to both the action of the gluteus maximus muscle, active when jumping and its rounded appearance.

Figures 11-86 and 11-87. Depending on point placement and needling angle, one may target any of the short lateral rotators depicted in these image, including the piriformis, gemellus superior, gemellus inferior, obturator internus, and quadratus femoris.

The piriformis muscle divides the greater sciatic foramen into the suprapiriformis and infrapiriformis foramina. The superior gluteal nerve exits the former while the inferior gluteal and sciatic nerves exit the latter.[7] Inferior gluteal entrapment neuropathy can arise as a complication of a dorsal, or posterior, approach to hip arthroplasty. Normally, the nerve exits the pelvis next to the sciatic nerve. Diagnosis of inferior gluteal entrapment neuropathy by MRI can be difficult due to the small size of the nerve. Astute myofascial palpation may localize the problem more quickly and less costly.

Vessels

- **Inferior gluteal artery:** Participates in the cruciate anastomosis of the thigh and anastomoses with the superior gluteal artery. Supplies the gluteus maximus, quadratus femoris, and the obturator internus muscles, as well as the proximal portions of the hamstring muscles. A major source of blood for the sciatic nerve.
- **Inferior gluteal vein:** Accompanies the inferior gluteal artery through the greater sciatic foramen, inferior to the piriformis muscle. Communicates with the femoral vein.

Clinical Relevance: Gluteal pain that radiates to the caudal thigh and calf makes many clinicians think first of lumbar disk disease or sciatica from piriformis syndrome and related myofascial dysfunction. However, patients with varicose veins may develop gluteal varicosities that compress the sciatic nerve.[8] Other reported sources of neurovascular compression syndromes in the vicinity of GB 30 include post-operative aneurysm of the gluteal artery and aberrant arterial loops. Although surgery or medication may be necessary for some severe patients, physical medicine measures should be considered whether or not more invasive or pharmacologic treatments are instituted. Laser therapy may ease the pain and inflammation and acupuncture may alleviate myofascial restriction and neuropathic pain.

In that the inferior gluteal artery provides the sciatic nerve with its primary blood supply, myofascial compression of the artery may deprive the nerve of adequate nourishment and oxygen, predisposing it to incur a neuropathic state. Treatment of the soft tissues with acupuncture and related techniques may be indicated.

Indications and Potential Point Combinations

- **Pain in the low back, pelvis, or hip:** GB 30, GB 39, BL 54, BL 40, GB 34, BL 62, BL 23, and trigger points involved in the generation and maintenance of the pain problem.
- **Problems with hip mobility or leg strength:** GB 30, GB 29, BL 54, BL 40, other pertinent trigger points.
- **Piriformis syndrome:** Consider GB 30, GB 31, GB 34, GB 39, BL 40, BL 60, ST 36;[9] add relevant trigger points, massage, laser therapy.
- **Sciatic nerve injury:**[10] GB 30, GB 34, BL 40, KI 3, other points along the sciatic nerve course. Target affected branches and muscles impacted. Include laser therapy for nerve regeneration and massage to remove myofascial compression.
- **Calcifying tendonitis of the gluteus medius:** GB 30, BL 23, BL 25, BL 28, and BL 30.[11]

Evidence-Based Applications

- Acupuncture at BL 23, BL 25, GB 30, BL 40, BL 60, and GB 34, plus BL 31, BL 32, and BL 54 (as needed) improved the orthopedic management of **chronic low back pain**.[1]
- Needling GB 30, GB 34, and BL 62 for **piriformis injury syndrome** outperformed needling at GB 30, GB 29, BL 36, and GB 34 in a reportedly randomized controlled trial.[2]
- Electroacupuncture at GB 30 and GB 34 significantly suppressed experimentally induced hyperalgesia, markedly inhibiting experimentally provoked cytokine increases; combining electroacupuncture with celecoxib resulted in a synergistic **analgesic** effect.[3]
- Daily electroacupuncture at GB 30 significantly alleviated experimentally induced hyperalgesia from **bone cancer pain** in rats, at least in part by suppressing dynorphin expression.[4]
- Electroacupuncture at GB 30 ever day for 30 minutes alleviated experimentally induced **bone cancer pain** at least in part by suppressing interleukin-1-beta expression.[5]
- Electroacupuncture at GB 30 and GB 34 appears to suppress spinal glial activation and behavioral hypersensitivity in experimentally induced **inflammatory pain states**.[6]

GB 31

Feng Shi "Wind Market"

On the lateral thigh, directly below the greater trochanter, 7 cun proximal to the transverse popliteal crease. With the patient standing with arms hanging freely and the hands close to the thighs, one finds the point where the tip of the middle finger touches the lateral thigh. Since the distance between the greater trochanter and the popliteal crease measures 19 cun, GB 31 lies at the tender spot approximately 1 cun proximal to the junction of the middle and lower thirds of this line.

Fascia

- **Fascia lata:** The strong and deep fascia of the lower limb envelops the muscles it contains like an elastic stocking. By preventing the muscles of the limb from bulging during contraction, blood returns from the limb to the heart more efficiently.
- **Iliotibial band:** The iliotibial band (ITB) constitutes a thickening of the fascia lata on the lateral aspect of the limb, originating from fibers of the gluteus maximus, gluteus medius, and tensor fasciae latae muscles. It functions in part as a tendon for these structures. The ITB attaches proximal to the knee joint into the lateral femoral condyle as well as distal to the knee into the infracondylar tubercle of the tibia. Where it attaches below the knee, it inserts onto the tibial and fibula. There, it trifurcates into three separate bands. One attaches to the lateral aspect of the patella, one to Gerdy's tubercle, and one to the fibular head and biceps femoris tendon and aponeurosis. View the extensive size of the iliotibial band in Figure 11-88. Considering its femoral and tibial mechanical connections, atypical or abnormal hip and lower limb movements could strain the ITB.

Clinical Relevance: At the knee, the ITB functions primarily as a lateral stabilizing ligament to the lateral hip and knee. The ITB performs a complex series of functions that aid in knee stabilization through both flexion and extension. Iliotibial band syndrome (ITBS) is considered the second leading cause of pain in runners. It has become the most common source of lateral

Figure 11-88. The GB line follows the caudal, or posterior, aspect of the iliotibial tract to the knee. Its intermediary position "between the two sinews" of the hamstrings and "quads" allows it to impact both extensors and flexors of the hip. Referred pain emanating from trigger points in the vastus lateralis muscle adheres closely to the trajectory outlined by the GB channel, extending from the hip to GB 34. The impact of GB 31 on tension, pain, and restricted mobility of the pelvic limb accounts for the point's name of "Wind Market". Wind and cold from the external environment further restricts movement by tightening (or shortening) the fascial band of the iliotibial tract and the veritable stocking formed by the fascia lata. "Wind Market" implies a concentration of this metaphorical wind at GB 31. It identifies a locus of pain and tension that manifests as a product of climatic factors affecting the thigh. Internal wind disorders in Chinese medicine indicate, in contrast, dysfunction caused by neurologic impairment. Paresis and paralysis of the lower limb due to peripheral or central nervous system lesions impair movement and induce contractures; GB 31 may assist in the recovery of lower limb function by attending to myofascial restrictions in this region.

knee pain.[3] Female runners who develop this syndrome exhibit limb kinematics suggestive of increased stress placed on the iliotibial band. While making adjustments in posture and limb motions during exercise would aid ITBS, acupuncture, massage, and laser therapy applied to the hip, ITB, and knee insertions supports recovery as well.

Muscles

- **Vastus lateralis muscle:** Extends the knee.
- **Vastus intermedius muscle:** Extends the knee.
- **Biceps femoris muscle:** Flexes the leg and, when the knee flexes, rotates the leg in a lateral direction. Extends the thigh at the hip when walking begins, keeping the trunk erect. Controls flexion at the hip during standing and forward bending. The short head of the bicep femoris, in particular, flexes the knee to allow the toes to clear the ground during ambulation.

Clinical Relevance: Pain in the hamstrings may cause patients to overload the quadriceps. Shortened hamstrings disrupt the biomechanical balance of walking and standing, promoting the spread and recurrence of trigger points in other muscles as weight is redistributed to compensate for unloading the painful muscle.

Travell and Simons call the quadriceps femoris group the "four-faced trouble maker". Individually, the rectus femoris is called "the two-jointed puzzler"; the vastus medialis is "the buckling knee muscle", the vastus intermedius is "the frustrator", and the vastus lateralis is "the stuck patella muscle" and exhibits the largest bulk of the four.

Five trigger point locations in the vastus lateralis have the potential to issue pain patterns along the entire thigh to the knee along the GB pathway. Superficial trigger points refer pain locally whereas deeper pathology produces deep pain that "explodes" in proximal and caudal directions. Pain typically worsens when lying on that side at night, interrupting sleep. The sense of having a "stuck patella" erupts from trigger points in the GB 32/GB 33 portion of the GB trajectory. These sites send pain toward the knee that may seem to enter into and through the knee. In fact, trigger points in and around GB 31 through GB 33 may refer pain as far proximad as GB 29 (almost to GB 26) and as far distad as GB 34. Travell and Simons refer to this cluster of myofascial consolidation as a "hornet's nest" of trigger points. About one-third of children with myofascial pain harbor trigger points in the vastus lateralis muscle.

In particular, trigger points in the vastus lateralis that abut the fascia lata can issue a pain sensation described as akin to a "bolt of lightning". Muscles affected by needling GB 31 depend on the depth of needle insertion, as Figure 11-90 displays.

Dubbed the "frustrator" muscle, the vastus intermedius develops difficult-to-find trigger points, hidden beneath the rectus femoris muscle. Pain from these trigger points extends over the front of the thigh and focus at mid-thigh.

Trigger points in the gluteus minimus muscle ("pseudo-sciatica" muscle) cause the patient to perceive pain in the buttock at GB 30 and the entire GB trajectory from the greater trochanter to GB 39 and on to the lateral malleolus.

Tensor fasciae latae muscle trigger points from GB 28 refer along the GB channel toward GB 31, GB 32, and almost reach GB 33.

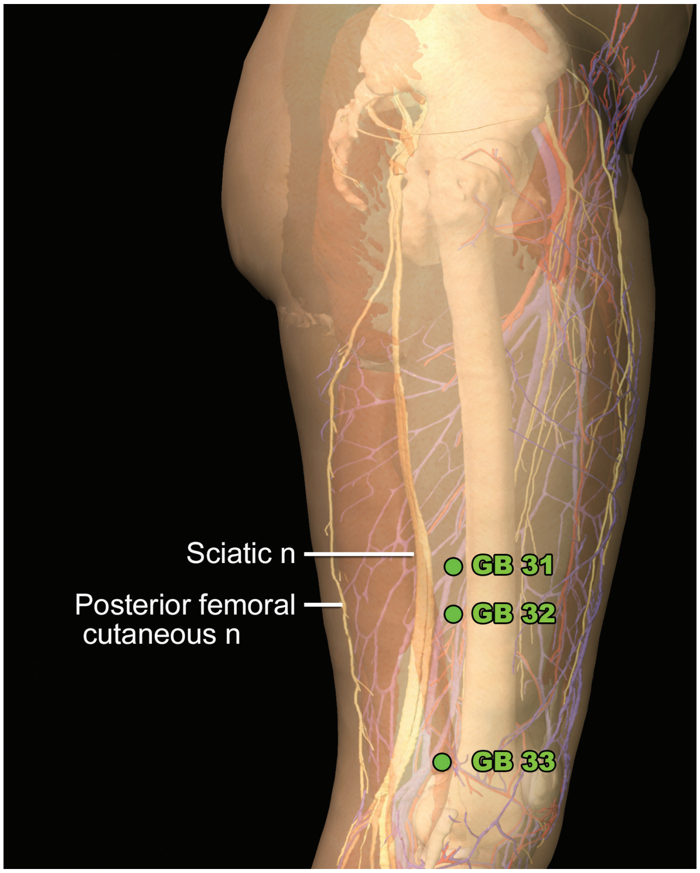

Figure 11-89. The "Internal Wind" alluded to in the name "Wind Market" for GB 31 metaphorically represents neurologic dysfunction in Chinese medicine. This image depicts two of the nerves potentially responsible for that dysfunction, including 1) the posterior femoral cutaneous nerve, supplying sensation to the buttock, perineum, posterior thigh, popliteal fossa, and proximal leg, and 2) the sciatic nerve, supplying motor function to the hamstrings and articular branches to the hip and knee joints. The posterior femoral cutaneous nerve supplies more skin than does any other cutaneous nerve. Although it does not lie directly in sight of the GB channel, this nerve is vulnerable to tension caused by restriction in the fascia affiliated with the GB line. That is, the posterior femoral cutaneous nerve lies deep to the fascia lata (the "deep fascia") and sends its sprigs to the skin. Excessive tension in the fascial stocking hinted at here could disrupt sensation due to nerve compression. The sciatic nerve provides motor supply to the hamstrings and the leg as well as sensation to most of the leg and all of the foot. The lateral femoral cutaneous nerve, while not visible in this image, supplies sensation to the lateral aspect of the thigh along the GB trajectory.

Trigger points in the biceps femoris, as with other hamstring muscles, can cause the patient to limp; the pain of placing a load on these muscles may also inhibit muscle function and reduce hip stability. Trigger points in the vicinity of GB 31 could arise in either the short or long head of the biceps femoris muscle; pain refers strongly to the popliteal fossa and may extend down the entire caudolateral thigh.

Nerves

- **Lateral femoral cutaneous nerve (L2, L3):** Innervates the skin the anterior thigh and the lateral aspect, from the greater trochanter to the knee.
- **Femoral nerve (L2-L4):** Innervates the muscles of the anterior

Figure 11-90. The robust muscles and formidable fascia within reach of GB 31 highlight why early Chinese acupuncturists named this point the "Wind Market". Cold and wind constrict the tissue; acupuncture frees fascia and treats triggers incited by wind, cold, and neurologic compromise.

thigh, hip, and knee, as well as the skin on the anteromedial thigh.

- **Sciatic nerve (L4-S3):** The sciatic nerve supplies the biceps femoris as well as the other hamstring muscles, the semitendinosus and semimembranosus muscles. It divides into the tibial and common fibular (common peroneal) nerves to supply the flexor muscles and extensor/abductor muscles of the leg, respectively. Supplies sensation to the leg below the knee and all of the foot, except for the medial calf and ankle (see LR line) that receives sensory supply by the saphenous branch of the femoral nerve. The sciatic nerve sends a small branch to the hip joint, as well as an articular branch to the knee joint. It fully supplies the ankle joint.

Clinical Relevance: Entrapment mononeuropathy of the lateral femoral cutaneous nerve has been implicated in meralgia paresthetica, a clinical syndrome involving burning pain and/or dysesthesia in the anterolateral thigh. Contributing factors to meralgia paresthetica include 1) Repetitive or continuous contraction or pathological shortening of the iliopsoas and sartorius muscles, 2) Pelvic tilt and limb length discrepancy that place heightened tension on the inguinal ligament, and 3) Anatomic variations that make the lateral femoral cutaneous nerve more vulnerable to compression.[4]

Input from Group III- and Group IV-mediated afferent feedback through the femoral nerve influences the voluntary termination of exercise. This suggests that somatic afferent stimulation in the quadriceps muscle group may reduce peripheral fatigue and improve muscular adaptation to exercise.[5]

Vessels

- **Lateral circumflex femoral artery, descending branch:** Descends to the knee to join the genicular anastomosis. May arise from either the deep artery of the thigh or the femoral artery.
- **Lateral circumflex femoral vein:** Often terminates in the femoral vein, but may drain into the deep femoral vein.
- **Inferior gluteal artery:** Supplies the sciatic nerve.

Clinical Relevance: Muscular compression and/or myofascial restriction in the anterolateral thigh may impede blood supply and drainage, facilitating the development and maintenance of myofascial trigger points in the region.

Indications and Potential Point Combinations

- **Pain in hip, thigh, or knee:** GB 31; analyze which components of the myofascial structures of the lower body are participating in causing this pain. Investigate both hamstring and quadriceps muscle groups.
- **Restricted hip mobility or hip instability:** GB 31, GB 29, GB 30, and targeted trigger points.
- **Weakness in the pelvic limbs:** GB 31, trigger points responsible for inhibiting motor function, neuroanatomically applicable points to address sciatic or femoral nerve dysfunction.
- **Generalized pruritus:** GB 31, LI 11.

Evidence-Based Applications

- Acupuncture at BL 23, BL 25, BL 26, BL 36, BL 40, BL 62, GB 31, and GB 34 for patients with **lumbar disc protrusion** resulted in significant pain reduction.[1]
- Warm needle acupuncture at GB 31 (a.k.a. moxibustion combined with needling) provided better **analgesia** compared to dry needling or moxibustion without needling in formalin-induced pain in rats.[2]
- In elderly patients following **total hip arthroplasty,** those who received transcutaneous electrical nerve stimulation (TENS) applied to ipsilateral GB 31 and bilateral LI 4, ST 36, and PC 6 required less fentanyl and reported less pain post-operatively for two days.[6]

Figure 11-91. GB 32, the "Middle Ditch", "Central Channel", or "Central River" exists in a deep groove between the flexor and extensor compartments of the thigh, demarcated by the lateral femoral intermuscular septum and the caudal border of the iliotibial tract. Figure 11-93 exposes the lateral intermuscular septum well.

Clinical Relevance: Pain in the hamstrings may cause patients to overload the quadriceps. Shortened hamstrings disrupt the biomechanical balance of walking and standing, promoting the spread and recurrence of trigger points in other muscles as weight is redistributed to compensate for unloading the painful muscle.

Travell and Simons call the quadriceps femoris group the "four-faced trouble maker". Individually, the rectus femoris is called "the two-jointed puzzler"; the vastus medialis is "the buckling knee muscle", the vastus intermedius is "the frustrator", and the vastus lateralis is "the stuck patella muscle" and exhibits the largest bulk of the four.

Five trigger point locations in the vastus lateralis have the potential to issue pain patterns along the entire thigh to the knee along the GB pathway. Superficial trigger points refer pain locally whereas deeper pathology produces deep pain that "explodes" in proximal and caudal directions. Pain typically worsens when lying on that side at night, interrupting sleep. The sense of having a "stuck patella" erupts from trigger points in the GB 32/GB 33 portion of the GB trajectory. These sites send pain toward the knee that may seem to enter into and through the knee. In fact, trigger points in and around GB 31 through GB 33 may refer pain as far proximad as GB 29 (almost to GB 26) and as far distad as GB 34. Travell and Simons refer to this cluster of myofascial consolidation as a "hornet's nest" of trigger points. About one-third of children with myofascial pain harbor trigger points in the vastus lateralis muscle.

In particular, trigger points in the vastus lateralis that abut the fascia lata can issue a pain sensation described as akin to a "bolt of lightning". Muscles affected by needling GB 32 depend on the depth of needle insertion, as Figure 11-93 shows.

Dubbed the "frustrator" muscle, the vastus intermedius develops difficult-to-find trigger points, hidden beneath the rectus femoris muscle. Pain from these trigger points extends over the front of the thigh and focus at mid-thigh.

Trigger points in the gluteus minimus muscle ("pseudo-sciatica" muscle) cause the patient to perceive pain in the buttock at GB 30 and the entire GB trajectory from the greater trochanter to GB 39 and on to the lateral malleolus.

Tensor fasciae latae muscle trigger points from GB 28 refer along the GB channel toward GB 31, GB 32, and almost reach GB 33.

Trigger points in the biceps femoris, as with other hamstring muscles, can cause the patient to limp; the pain of placing a load on these muscles may also inhibit muscle function and reduce hip stability. Trigger points in the vicinity of GB 32 could arise in either the short or long head of the biceps femoris muscle as revealed by Figure 11-93; pain from these sites refers strongly to the popliteal fossa and may extend down the entire caudolateral thigh.

Nerves

- **Lateral femoral cutaneous nerve (L2, L3):** Innervates the skin the anterior and lateral parts of the thigh.
- **Femoral nerve (L2-L4):** Innervates the muscles of the anterior thigh, hip, and knee, as well as the skin on the anteromedial thigh.
- **Sciatic nerve (L4-S3):** The sciatic nerve supplies the biceps femoris as well as the other hamstring muscles, the semitendinosus and semimembranosus muscles. It divides into the tibial and common fibular (common peroneal) nerves to supply the flexor muscles and extensor/abductor muscles of the leg, respectively. Supplies sensation to the leg below the knee and all of the foot, except for the medial calf and ankle (see LR line) that receives sensory supply by the saphenous branch of the femoral nerve. The sciatic nerve sends a small branch to the hip joint, as well as an articular branch to the knee joint. It fully supplies the ankle joint.

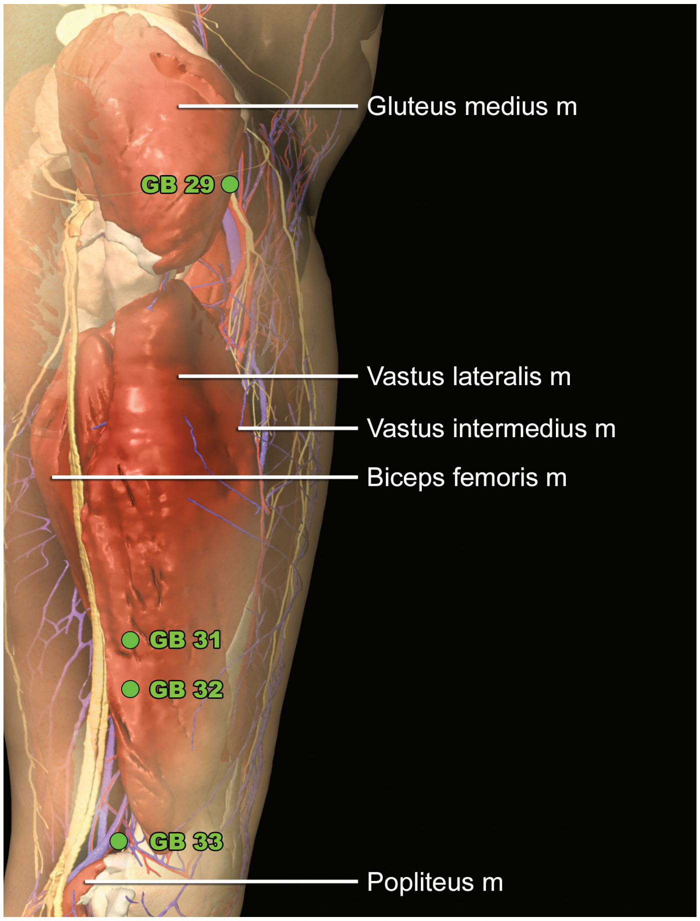

Figure 11-92. This image explores the relationship between the deep muscles of the hip and thigh to GB 29, GB 31, GB 32, and GB 33. Each location designates a region rich with trigger points.

Clinical Relevance: Entrapment mononeuropathy of the lateral femoral cutaneous nerve has been implicated in meralgia paresthetica, a clinical syndrome involving burning pain and/or dysesthesia in the anterolateral thigh. Contributing factors to meralgia paresthetica include 1) Repetitive or continuous contraction or pathological shortening of the iliopsoas and sartorius muscles, 2) Pelvic tilt and limb length discrepancy that place heightened tension on the inguinal ligament, and 3) Anatomic variations that make the lateral femoral cutaneous nerve more vulnerable to compression.

Input from Group III- and Group IV-mediated afferent feedback through the femoral nerve influences the voluntary termination of exercise. This suggests that somatic afferent stimulation in the quadriceps muscle group may reduce peripheral fatigue and improve muscular adaptation to exercise.

The posterior femoral cutaneous nerve supplies more skin than does any other cutaneous nerve. Although it does not lie directly

Figure 11-93. GB 32 provides access to the short and long heads of the biceps femoris muscle along with the vastus lateralis and vastus intermedius, depending on angle and depth of needle insertion. As a cautionary note, examine the relationship of the sciatic nerve to GB 32, i.e., it lies well within reach of a deeply placed needle.

in sight of the GB channel, this nerve is vulnerable to tension caused by restriction in the fascia affiliated with the GB line. That is, the posterior femoral cutaneous nerve lies deep to the fascia lata (the "deep fascia") and sends its sprigs to the skin. Excessive tension in the fascial stocking hinted at here could disrupt sensation due to nerve compression. The sciatic nerve provides motor supply to the hamstrings and the leg as well as sensation to most of the leg and all of the foot. The lateral femoral cutaneous nerve, while not visible in this image, supplies sensation to the lateral aspect of the thigh along the GB trajectory.

Vessels

- **Lateral circumflex femoral artery, descending branch:** Descends to the knee to join the genicular anastomosis. May arise from either the deep artery of the thigh or the femoral artery.
- **Lateral circumflex femoral vein:** Often terminates in the femoral vein, but may drain into the deep femoral vein.

Clinical Relevance: Muscular compression and/or myofascial restriction in the anterolateral thigh may impede blood supply and drainage, facilitating the development and maintenance of myofascial trigger points in the region.

Indications and Potential Point Combinations

- **Pain in hip, thigh, or knee:** GB 32 or GB 31; analyze which components of the myofascial structures of the lower body are participating in causing this pain. Investigate both hamstring and quadriceps muscle groups. Pain in the hamstrings may cause patients to overload the quadriceps. Shortened hamstrings disrupt the biomechanical balance of walking and standing, promoting the spread and reappearance of trigger points in other muscles as weight is redistributed to compensate for unloading the painful muscle. Trigger points in the vastus lateralis muscle, a member of the quadriceps femoris pack, erupt at GB 31, GB 32, and GB 33, and pain refers to GB 34 and/or the popliteal fossa region, at BL 38, BL 39, and BL 40.
- **Restricted hip mobility or hip instability:** GB 32, GB 31, GB 29, GB 30, and targeted trigger points.
- **Weakness in the pelvic limbs:** GB 32, trigger points responsible for inhibiting motor function, neuroanatomically applicable points to address sciatic or femoral nerve dysfunction.

GB 33

Xi Yang Guan "Knee Yang Joint"

On the lateral aspect of the knee, proximal to the joint line, in a depression between the biceps femoris muscle and the iliotibial tract, approximately 3 cun proximal to GB 34. Can be found by palpating along the groove between the femur and the biceps femoris and locating the site where the finger enters a depression just proximal to the lateral epicondyle of the femur.

Fascia

- **Fascia lata:** The strong and deep fascia of the lower limb envelops the muscles it contains like an elastic stocking. By preventing the muscles of the limb from bulging during contraction, blood returns from the limb to the heart more efficiently.
- **Iliotibial band:** The iliotibial band (ITB) constitutes a thickening of the fascia lata on the lateral aspect of the limb, originating from fibers of the gluteus maximus, gluteus medius, and tensor fasciae latae muscles. It functions in part as a tendon for these structures. The ITB attaches proximal to the knee joint into the lateral femoral condyle as well as distal to the knee into the infracondylar tubercle of the tibia. Where it attaches below the knee, it inserts onto the tibial and fibula. There, it trifurcates into three separate bands. One attaches to the lateral aspect of the patella, one to Gerdy's tubercle, and one to the fibular head and biceps femoris tendon and aponeurosis. View the extensive size of the iliotibial band in Figure 11-88. Considering its femoral and tibial mechanical connections, atypical or abnormal hip and lower limb movements could strain the ITB.

Clinical Relevance: At the knee, the ITB functions primarily as a lateral stabilizing ligament to the lateral hip and knee. The ITB performs a complex series of functions that aid in knee stabilization through both flexion and extension. Iliotibial band syndrome (ITBS) is considered the second leading cause of pain in runners. It has become the most common source of lateral knee pain.[2] Female runners who develop this syndrome exhibit limb kinematics suggestive of increased stress placed on the iliotibial band. While making adjustments in posture and limb motions during exercise would aid ITBS, acupuncture, massage, and laser therapy applied to the hip, ITB, and knee insertions supports recovery as well.

Muscles

- **Biceps femoris muscle and tendon:** Flexes the leg and, when the knee flexes, rotates the leg in a lateral direction. Extends the thigh at the hip when walking begins, keeping the trunk erect. Controls flexion at the hip during standing and forward bending. The short head of the bicep femoris, in particular, flexes the knee to allow the toes to clear the ground during ambulation.

Clinical Relevance: Pain in the hamstrings may cause patients to overload the quadriceps. Shortened hamstrings disrupt the biomechanical balance of walking and standing, promoting the spread and recurrence of trigger points in other muscles as weight is redistributed to compensate for unloading the painful muscle. Trigger points in the biceps femoris, as with other hamstring muscles, can cause the patient to limp; the pain of placing a load on these muscles may also inhibit muscle function and reduce hip stability. Trigger points in the vicinity of GB 33 could arise in either the short or long head of the biceps femoris muscle; pain refers strongly to the popliteal fossa and may extend down the entire caudolateral thigh.

Trigger points in the gluteus minimus muscle ("pseudo-sciatica" muscle) cause the patient to perceive pain in the buttock at GB 30 and the entire GB trajectory from the greater trochanter to GB 39 and on to the lateral malleolus.

Tensor fasciae latae muscle trigger points from GB 28 refer along the GB channel toward GB 31, GB 32, and almost reach GB 33.

Nerves

- **Lateral femoral cutaneous nerve (L2, L3):** Innervates the skin the anterior and lateral parts of the thigh.
- **Sciatic nerve (L4-S3):** The sciatic nerve supplies the biceps femoris as well as the other hamstring muscles, the semitendinosus and semimembranosus muscles. It divides into the tibial and common fibular (common peroneal) nerves to supply the flexor muscles and extensor/abductor muscles of the leg, respectively. Supplies sensation to the leg below the knee and all of the foot, except for the medial calf and ankle (see LR line) that receives sensory supply by the saphenous branch of the femoral nerve. The sciatic nerve sends a small branch to the hip joint, as well as an articular branch to the knee joint. It fully supplies the ankle joint.

Clinical Relevance: Entrapment mononeuropathy of the lateral femoral cutaneous nerve has been implicated in meralgia paresthetica, a clinical syndrome involving burning pain and/

Figure 11-95. “Knee Yang Joint”, the descriptive name for GB 33, lives proximal to the knee joint. In Chinese medicine, “superior” locations are Yang relative to “inferior”, which are Yin; similarly, “lateral” is Yang compared to “medial, which is Yin. Thus, a point located proximal and lateral to the joint itself qualifies as the “Knee Yang Joint” point. This image depicts the right knee, lateral aspect.

or dysesthesia in the anterolateral thigh. Contributing factors to meralgia paresthetica include 1) Repetitive or continuous contraction or pathological shortening of the iliopsoas and sartorius muscles, 2) Pelvic tilt and limb length discrepancy that place heightened tension on the inguinal ligament, and 3) Anatomic variations that make the lateral femoral cutaneous nerve more vulnerable to compression.[3]

Input from Group III- and Group IV-mediated afferent feedback through the femoral nerve influences the voluntary termination of exercise. This suggests that somatic afferent stimulation in the quadriceps muscle group may reduce peripheral fatigue and improve muscular adaptation to exercise.[4]

The posterior femoral cutaneous nerve supplies more skin than does any other cutaneous nerve. Although it does not lie directly in sight of the GB channel, this nerve is vulnerable to tension caused by restriction in the fascia affiliated with the GB line. That is, the posterior femoral cutaneous nerve lies deep to the fascia lata (the “deep fascia”) and sends its sprigs to the skin. Excessive tension in the fascial stocking hinted at here could disrupt sensation due to nerve compression. The sciatic nerve provides motor supply to the hamstrings and the leg as well as sensation to most of the leg and all of the foot. The lateral femoral cutaneous nerve, while not visible in this image, supplies sensation to the lateral aspect of the thigh along the GB trajectory.

Vessels

- **Lateral circumflex femoral artery, descending branch:** Descends to the knee to join the genicular anastomosis. May arise from either the deep artery of the thigh or the femoral artery.
- **Lateral circumflex femoral vein:** Often terminates in the femoral vein, but may drain into the deep femoral vein.

Clinical Relevance: Muscular compression and/or myofascial restriction in the anterolateral thigh may impede blood supply and drainage, facilitating the development and maintenance of myofascial trigger points in the region.

Indications and Potential Point Combinations

- **Knee pain:** Determine source and location of knee pain. For lateral knee pain affiliated with the lateral collateral ligament, the insertion of the biceps femoris muscle or iliotibial tract onto the tibia, or the lateral meniscus, GB 33 may be appropriate, along with GB 32 and ST 44. Pain in the popliteal fossa referred from trigger points in the biceps femoris may warrant stimulation of GB 33, BL 40, and other pertinent myofascial problems.
- **Knee osteoarthritis:** GB 33, GB 34, ST 34, SP 10, ST 35, ST, 36, CV 12, CV 4, ST 26, and SP 15.[5]
- **TMJ dysfunction:** GB 33, GB 2, GB 7, GB 8, GB 20, GB 21.

Evidence-Based Applications

- Supramaximal percutaneous electrical stimulation applied to the peroneal nerve through a surface electrode near GB 33 transiently disturbed stabilization of the postural stance; voluntary teeth clenching restored this stabilization. This study demonstrated the relationship between **1) activation of the motor portion of the trigeminal nerve as it contracts masseter muscle and 2) rapid postural adaptation to anterior-posterior perturbation of the upright position.**[1] These findings reinforce growing evidence linking lower limb function with reflexes affecting the trigeminal nerve. Further, it supports the contention that patients should rest after acupuncture and not engage in strenuous or athletic activity immediately after treatment in order to allow the body to adapt to the proprioceptive changes caused by some types of somatic afferent stimulation.
- Acupuncture applied to GB 33 affects **oxygen saturation** in the tissue to a depth of 2-4 cm.[6]

GB 34

Yang Ling Quan "Yang Mound Spring"

In a depression approximately 1 cun cranial and distal to the head of the fibula.

Note: Excessively deep, vigorous, and/or otherwise incorrect needling practices could injure the peroneal (fibular) nerve at GB 34.[25,26]

Muscles

- **Peroneus (Fibularis) longus muscle:** Everts the foot and, to a lesser degree, plantarflexes the ankle.
- **Extensor digitorum longus muscle:** Extends the lateral four digits; dorsiflexes the ankle. In conjunction with the extensor hallucis longus muscle, the extensor digitorum longus muscle functions to help control, or slow down, the descent of the forefoot to the floor right after heel-strike. This averts "foot-slap". Prevents excessive postural sway backward.

Clinical Relevance: Taut bands in the peroneus (fibularis) longus muscle can compress the superficial and deep branches of the peroneal (fibularis) nerve and lead to significant problems with food drop and paresthesias. Trigger points in the peroneal (fibularis) muscles may cause "weak ankles".

Trigger points in the extensor digitorum longus muscle refer pain down the GB line to the foot and toes. Taut bands in the extensor digitorum longus may compress the deep peroneal nerve against the fibula and induce foot-drop. Treatment options include deactivation of the trigger points and taut bands responsible for the neuropraxia by means of acupuncture, laser therapy, and/or soft tissue manual therapy. These should be tried, ideally, before pursuing surgery.

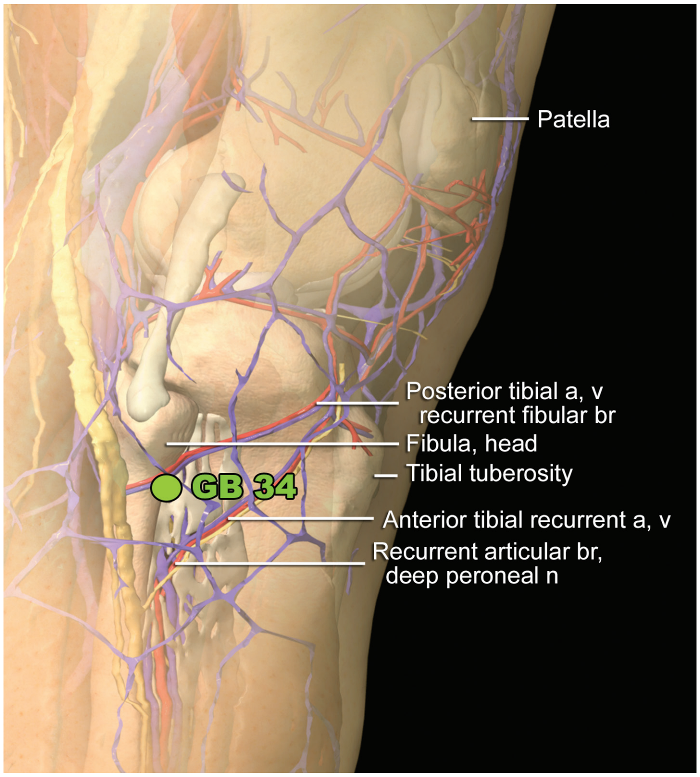

Figure 11-97. The "Yang Mound" at GB 34 refers to the fibular head, a prominence on the outer, or Yang, aspect of the knee. "Spring" speaks to the neurovascular structures participating in the genicular anastomoses. The Yin, or medial knee counterpart for "Yang Mound Spring" (GB 34) is SP 9, called "Yin Mound Spring".

Nerves

- **Recurrent articular nerve from common peroneal (fibular) nerve:** Supplies the knee joint.
- **Lateral sural cutaneous nerve (L5):** A branch of the common peroneal (fibular) nerve that innervates the skin on the lateral part of the caudal crus.
- **Superficial peroneal (fibular) nerve ((L4)L5-S2):** Innervates the peroneus (fibularis) longus and brevis muscles. Supplies the dorsal skin on the distal third of the crus and most of the dorsum of the foot.
- **Deep peroneal (fibular) nerve ((L4)L5-S1):** Supplies motor function to the extensor digitorum longus and brevis, the extensor hallucis longus, and the peroneus (fibular) tertius muscles. Innervates the skin of between the 1st and 2nd digits and metatarsi. Emits articular branches to the joints it crosses.
- **Common peroneal (fibular) nerve:** Winds around the neck of the fibula after passing over the caudal aspect of the head. Travels deep to the peroneus (fibularis) longus where it then divides into its superficial and deep branches. Innervates the skin on the lateral aspect of the caudal crus via the lateral sural cutaneous nerve. Supplies the knee joint with an articular branch.

Clinical Relevance: Several sites of entrapment threaten the common peroneal (fibular) nerve and its branches. The first locus of entrapment involves the common peroneal (fibular) nerve trunk. This occurs at the peroneal (fibular) tunnel – a soft tissue opening between the two heads of the peroneus (fibularis) longus muscle where its two heads attach onto the fibula. Because the lateral sural cutaneous nerve has branches off of the common peroneal (fibular) nerve by the time the trunk arrives at the tunnel, this branch escapes entrapment. Note the anatomy of these nerves and muscles made apparent in Figure 11-98.

Inside the tunnel, the common peroneal (fibular) nerve divides into three nerves: the deep, superficial, and recurrent peroneal (fibular) nerves. All three nerves may undergo traction and compression as they cross the fibular neck. Tension in the soft tissue may force the nerves against the fibular neck, manifesting as impaired sensation, movement, or pain.[27]

Patients with common peroneal (fibular) nerve syndrome (i.e., neuropathic compression of the nerve trunk) report pain near GB 34 and along the GB channel. Pain worsens with exercise and pressure applied to the site of entrapment. Muscles affected by common peroneal (fibular) nerve syndrome demonstrate weakness of ankle dorsiflexion and inversion. Forcing the ankle into an inversion position accentuates discomfort. Chronic entrapment may cause foot drop.

Types of external compression that incite entrapment include osteophytes, surgery, tight plaster casts, ganglion or synovial cysts, crossed-leg sitting posture, constrictive clothing, and binding hosiery. Repetitive exercises that induce or worsen the problem include those involving repeated inversion and pronation. Examples include running, cycling, and the operation of certain machines. Figure 11-98. The reputation of GB 34 for treating the "sinews" or connective tissue, may derive from the many nearby intersecting structures, including the biceps femoris tendon, the lateral (fibular) collateral ligament, the lateral gastrocnemius tendon, fabellofibular ligament, mid third lateral capsular ligament, popliteofibular ligament, popliteus muscle and tendon, and the iliotibial band.[44] Note the way in which the common peroneal (fibular) nerve dives deep to the peroneus (fibularis) longus in this lateral view of the right knee as it enters the peroneal (fibular) tunnel discussed earlier.

the superficial peroneal (fibular) nerve may spill over into injuring the trunk as well.

Distal to the peroneal (fibular) tunnel, the deep peroneal (fibular) branch follows the ST line while the GB channel accompanies the superficial peroneal (fibular) nerve branch, following the fibula and peroneus (fibularis) longus muscle.

At about the junction of the distal and middle third of the fibula, near GB 35, GB 36, and GB 37 territory, the superficial peroneal (fibular) nerve sends a branch to the peroneus (fibularis) brevis muscle. This branch may suffer compression as it makes its way to the brevis between the fibular and peroneus (fibularis) longus muscle.

Compression of the superficial peroneal (fibular) nerve by the crural fascia causes "superficial peroneal (fibular) nerve syndrome". Near GB 37 and GB 38, this nerve emerges through the crural fascia and divides into two cutaneous branches. Fascial restriction may compress the branches as they cross the cranial ankle. If this occurs, sensation may be impaired to the craniolateral distal crus, the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory supply from the deep peroneal (fibular) nerve. (See LR 2 and LR 3.)

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation that follows the GB channel onto the dorsum of the foot, extending to the sensory territory of the dorsal superficial branch and thus incorporating parts of the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer.

Nonsurgical approaches to releasing the nerve and fascial restriction should be considered and initiated prior to surgery in order to assess their ability to reduce pain and nerve injury without surgery.[28]

Vessels

- **Inferior lateral genicular artery:** One of several arteries contributing to the anastomosis around the knee, known as the genicular anastomosis. These vessels provide collateral circulation to the knee if the popliteal vessels are occluded.
- **Anterior tibial recurrent artery (ATRA):** A branch of the anterior tibial artery that arises after the artery emerges from the interosseous space; helps provide circulation to the knee. Connects the anterior tibial artery to the genicular anastomosis and supplies structures in this region, including the lateral tibial condyle.[29] That ATRA anastomoses with the inferior lateral genicular artery (a branch of the popliteal artery) with branches surrounding the

lateral intercondylar tubercle and the femoro-tibial joint capsule.

Clinical Relevance: The ATRA branches off of the anterior tibial artery (ATA) in the vicinity of ST 36, near GB 34. (See Figure 11-97 to view the branching pattern.) Thus, improving circulation through acupuncture at ST 36 and GB 34 not only influences multiple levels of nerve function, but also improves hemodynamics of knee and surrounding structures. Arthroscopy of the joint, tibial fracture repair, and sub-meniscal arthrotomy may damage these delicate vessels, requiring support through neuro- and circulatory modulation by means of acupuncture and related techniques.

Indications and Potential Point Combinations

- **Generalized muscle or tendon pain:** GB 34, local trigger points.
- **Pelvic limb weakness associated with peroneal nerve injury:** GB 34, LR 2, LR 3, ST 36, trigger points or taut bands in the peroneus longus and/or extensor digitorum longus muscles.
- **Knee pain:** GB 34, ST 36, ST 34, SP 10, SP 9, BL 40, pertinent trigger points. Consider ST 35, Xiyan (eyes of the knee), and SP 6 in addition to the aforementioned points.[30]

Evidence-Based Applications

- Case series reported effectiveness in treating **shoulder pain, elbow pain, lateral thoracic pain, lumbar pain, and gastrocnemius spasm.**[1]
- Acupuncture at BL 23, BL 25, GB 30, BL 40, BL 60, and GB 34, plus BL 31, BL 32, and BL 54 (as needed) improved the orthopedic management of **chronic low back pain.**[2]
- **Reduces alpha-motoneuron excitability** when researchers needled GB 34 and SP 9 for 15 minutes of manual acupuncture.[3]
- Needling at GB 34 **reduced motor system excitability** when transcranial magnetic stimulation (TMS) parameters were measured at the abductor digiti minimi muscle 15 minutes before and after needling.[31]
- Transcutaneous electrical acupoint stimulation (TEAS) at GB 34, BL 57, ST 36, and SP 6 enhanced the rate of **muscle force recovery following fatigue of the quadriceps.**[32] Stimulation did not alter lactate removal or restitution of median power frequency of the vastus medialis.
- Acupuncture at GB 34, GB 37, GB 39, LI 4, LI 11, LI 13, LI 15, GB 20, PC 6, ST 36, SP 6, LU 7, and LR 3, among other sites may enhance **exercise performance and support post-exercise recovery.**[33]
- Electroacupuncture at ST 38 and GB 34 provided significantly more relief for patients with **tennis elbow** than did manual acupuncture.[4]
- Acupuncture at GB 34 provided more relief of **chronic tennis elbow pain** than BL 13.[5]
- Acupuncture at GB 34 **modulates the cortical activities of the somatomotor area** in humans.[6,34]
- Acupuncture was shown to be an effective and safe adjunctive therapy for patients with **knee osteoarthritis**, using the following points: GB 34, GB 39, SP 6, SP 9, ST 35, ST 36, KI 3, and Xiyan.[7]
- Acupuncture at SI 3, SI 14, LR 3, BL 10, BL 60, GB 20, GB 34, TH 5, trapezius myofascial trigger point, and the auricular point "cervical spine" provided greater pain relief of **chronic neck pain** compared to massage, but not sham laser.[8]
- Acupuncture applied to GB 34, GB 20, TH 5, ST 8, LI 6, and ST 36 **reduced pain** and altered cerebral glucose metabolism in pain-related brain regions **in migraineurs** according to PET-CT findings.[35]
- Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve **reduction of sympathetic nervous system activity.**[36,37]
- Acupuncture at BL 23, BL 25, BL 26, BL 36, BL 40, BL 62, GB 31, and GB 34 for patients with **lumbar disc protrusion** resulted in significant pain reduction.[9]
- **Lowers blood pressure** and may help prevent cardiac muscle hypertrophy.[10]
- Needling GB 34, ST 36, SP 6, and BL 67 may help decrease the need for **labor induction** and cesarean section.[11]
- Prophylactic use of bilateral noninvasive acuplaster on BL 10, BL 11, and GB 34 significantly reduces **vomiting in children after strabismus correction.**[12]
- Acupuncture at GB 34, PC 6, and BL 11 has become more accepted in the clinical management of **postoperative vomiting after strabismus surgery** in children.[13]
- Acupressure to KI 1, GB 34, ST 36, and SP 6 helped relieve **fatigue in patients with end-stage renal disease.**[14]
- Acupuncture at ST 36 and GB 34 may exert their **hypotensive effects by decreasing renin secretion.**[15]
- Electroacupuncture at GB 34 elicited significantly higher activation of the hypothalamus and primary somatosensory-motor cortex than did sham treatment. It caused stronger deactivation over the rostral segment of the anterior cingulate cortex. Thus, electroacupuncture at real acupuncture points **modulated hypothalamus-limbic function** significantly more than did sham points.[16]
- Electroacupuncture at ST 36 + SP 6 was compared to GB 34 + BL 57, in order to study differences in brain activation from acupuncture points located in the same spinal segments. Both overlapping and distinct cerebral response patterns from stimulation of the two pairs were observed. Both pairs of points (ST 36/SP 6 and GB 34/BL 57) activated the primary and secondary somatosensory areas, insula, ventral thalamus, parietal Brodmann Area 40, temporal lobe, putamen, and cerebellum; both deactivated the amygdala. However, ST 36/SP 6 specifically activated the orbital frontal cortex and deactivated the hippocampus, while GB 34/BL 57 activated the dorsal thalamus and inhibited the primary motor area and premotor cortex. These cerebral response differences may help explain why ST 36/SP 6 is indicated more for visceral disorders and pain while GB 34/BL 57 are important points for **modulation of muscle and tendon function and motor output.**[17]
- Electroacupuncture at GB 34 and GB 39 modulates **sympathetic nervous system activity** in the brain, possibly accounting in part for the analgesic effects of these two points.[38]
- Acupressure at GB 34, ST 36, SP 9, and SP 6 caused significant increases in lower leg blood flow in patients with Stage II **peripheral arterial occlusive diseases.**[39]

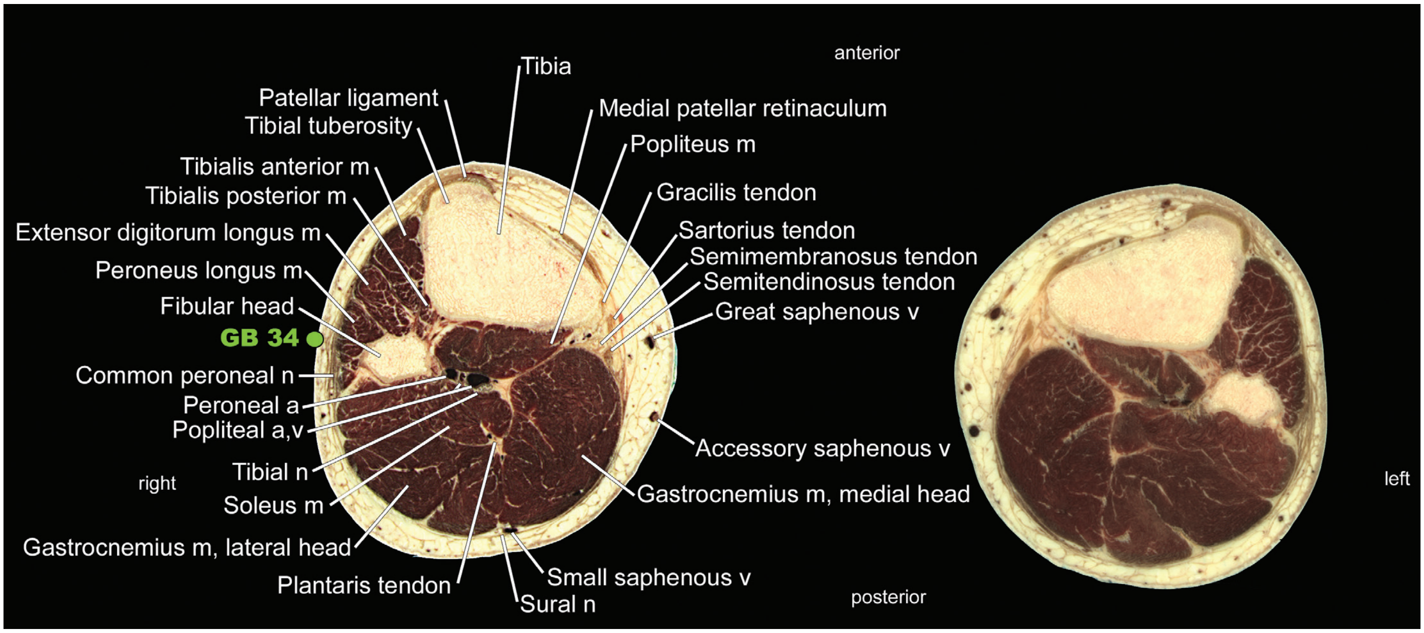

Figure 11-99. The proximity of the common peroneal nerve to GB 34 underscores the impact of this point on peroneal (fibular) nerve function and the tissues it supplies. Note, as well, the cramped quarters in this craniolateral compartment of the crus. These crowded conditions raise the risk of nerve entrapment.

- The "three needling method" for **piriformis injury syndrome** that involves GB 30, GB 34, and BL 62 outperformed the routine approach for this condition treated by GB 30, BL 36, and GB 34.[18]
- GB 34 and LR 3 delivered neuroprotective effects against neuronal death in a **Parkinson's disease** model.[19]
- Acupuncture at GB 34 increased activation of the putamen and primary motor cortex in patients with **Parkinson's disease.**[40]
- Acupuncture at GB 34 increased neural responses in brain areas injured by **Parkinson's disease.** These regions included the substantia nigra, caudate, thalamus, and putamen.[41]
- Electroacupuncture stimulation of GB 34 produced a significant decrease in **Sphincter of Oddi motility** and concomitant increase in cholecystokinin levels. These changes returned to baseline after discontinuation of the electrical stimulation.[20]
- Electroacupuncture stimulation of GB 34 and GB 30 significantly suppressed experimentally induced spinal **glial activation.**[21]
- It significantly suppressed experimentally induced hyperalgesia and markedly inhibited cytokines associated with **inflammation,** including PGE2, IL-1beta, IL-6, and TNF-alpha in the spinal cord.[22]
- Acupuncture provides substantial pain relief for patients with **chronic pain following spinal cord injury.** Medical acupuncturists stimulated GV 14 in all patients. In addition, Huatuojiaji points were selected at the level of the lesion. BL 10 was selected for lesions cranial to T1. Below L5, BL 40 was selected. Patients who did not respond satisfactorily to adding either BL 10 or BL 40 were then stimulated at both sites. Additional points depending on the pain location included Baxie or Bafeng points on an affected hand or foot, respectively. Points on the limbs were added according to the channel and surface affected. Thus, GB 34 was included when pain affected the lateral leg.[42]
- Stimulation of the fibular nerve with functional electrical stimulation (with mechanisms similar to electroacupuncture) **reduces foot drop and increases walking speed** in patients with spastic paraparesis.[43]
- Electroacupuncture at GB 34, GB 36, TH 8, and LI 4 **reduced postoperative narcotic analgesic requirements in patients following thoracotomy.**[23]
- Manual acupuncture at GB 34, GV 20, LI 4, CV 3, CV 4, CV 6, BL 23, SP 6, and auricular Shen Men produced a statistically significant reduction in symptoms of **primary dysmenorrhea** for one year.

GB 35

Yang Jiao "Yang Intersection"

On the lateral crus, caudal to the fibula, 7 cun proximal to the most prominent part of the lateral malleolus, level with GB 36, ST 39, and BL 58. Given that the distance between the lateral malleolus and the popliteal crease measures 16 cun, GB 35 lands 1 cun distal to the midpoint of this line.

Muscles

- **Peroneus (Fibularis) longus muscle:** Everts the foot and, to a lesser degree, plantarflexes the ankle.
- **Peroneus (Fibularis) brevis muscle:** Everts the foot.

Clinical Relevance: Taut bands in the peroneus (fibularis) longus muscle can compress the superficial and deep branches of the peroneal (fibularis) nerve and lead to significant problems with foot drop and paresthesias.

Trigger points in the peroneus brevis issue pain along the caudal border of the fibula to the lateral malleolus, then onto the dorsum of the foot toward GB 42.

Trigger points in the peroneal (fibularis) muscles may cause the feeling of having "weak ankles".

Nerves

- **Lateral sural cutaneous nerve (L5-S1):** A branch of the common peroneal nerve that innervates the skin on the lateral part of the posterior leg.
- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot, on their anterior surfaces.

Clinical Relevance: Several sites of entrapment threaten the common peroneal (fibular) nerve and its branches. The first locus of entrapment involves the common peroneal (fibular) nerve trunk. This occurs at the peroneal (fibular) tunnel – a soft tissue opening between the two heads of the peroneus (fibularis) longus muscle where its two heads attach onto the fibula. Because the lateral sural cutaneous nerve has already branched off of the common peroneal (fibular) nerve by the time the trunk arrives at the tunnel, this entity escapes entrapment. Note the anatomy of these nerves and muscles made apparent in Figure 11-98.

Inside the tunnel proximal to GB 34, the common peroneal (fibular) nerve divides into three nerves: the deep, superficial, and recurrent peroneal (fibular) nerves. All three nerves may undergo traction and compression as they cross the fibular neck. Tension in the soft tissue may force the nerves against the fibular neck, manifesting as impaired sensation, movement, or pain.[1]

Distal to the peroneal (fibular) tunnel, the deep peroneal (fibular) branch follows the ST line while the GB channel accompanies the superficial peroneal (fibular) nerve branch, following the fibula and peroneus (fibularis) longus muscle to GB 39.

At about the junction of the distal and middle third of the fibula where GB 35, GB 36, and GB 37 lie, the superficial peroneal (fibular) nerve sends a branch to the peroneus (fibularis) brevis muscle. This branch may suffer compression as it makes its way to the brevis between the fibular and peroneus (fibularis) longus muscle.

Compression of the superficial peroneal (fibular) nerve by the crural fascia causes "superficial peroneal (fibular) nerve syndrome". Near GB 37 and GB 38, this nerve emerges through the crural fascia and divides into two cutaneous branches. Fascial restriction may compress the branches as they cross the cranial ankle. If this occurs, sensation may be lessened to the craniolateral distal crus, the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory supply from the deep peroneal (fibular) nerve. (See LR 2 and LR 3.)

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation that follows the GB channel onto the dorsum of the foot, extending to the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer.

Nonsurgical approaches that release the nerve and surrounding fascial restriction should be considered prior to surgery.[2]

popliteus and other muscles occupying the posterior and lateral compartments of the leg. Supplies a nutrient artery to the fibula.

Clinical Relevance: Ankle injuries involving the tibiofibular syndesmosis raise the likelihood of producing prolonged ankle discomfort and disability.[3] In part, this is due to the possible disruption of the primary vascular supply to anterior ankle ligaments, i.e., the peroneal (fibular) artery at its perforating branch.

Indications and Potential Point Combinations

- **Feeling of weak ankles associated with peroneal trigger points:** GB 35, GB 34, GB 39, and LR 2.
- **Cramping pain on the lateral leg and/or peroneal nerve entrapment causing paresthesias and, possibly, foot drop:** GB 35, GB 38, GB 34, LR 3.

GB 36

Wai Qiu “Outer Hill”

On the lateral crus, cranial to the fibula (in contrast to GB 35, which was caudal to the fibula). 7 cun proximal to the most prominent part of the lateral malleolus, level with GB 35, ST 39, and BL 58. Given that the distance between the lateral malleolus and the popliteal crease measures 16 cun, GB 35 lands 1 cun distal to the midpoint of this line.

Muscles

- **Peroneus (Fibularis) longus muscle:** Everts the foot and, to a lesser degree, plantarflexes the ankle.
- **Peroneus (Fibularis) brevis muscle**: Everts the foot.
- **Extensor digitorum longus muscle:** Extends the lateral four digits; dorsiflexes the ankle.
- **Extensor hallucis longus muscle:** Extends the great toe and dorsiflexes the ankle.

Clinical Relevance: Taut bands in the peroneus (fibularis) longus muscle can compress the superficial and deep branches of the peroneal (fibularis) nerve, thereby causing significant problems with foot drop and paresthesias.

Trigger points in the peroneus brevis issue pain along the caudal border of the fibula to the lateral malleolus, then onto the dorsum of the foot toward GB 42.

Trigger points in the peroneal (fibularis) muscles may cause the feeling of having “weak ankles”.

Referred pain from extensor digitorum longus trigger points near GB 36 issue pain along the distal GB channel on the dorsum of the foot.

A trigger point in the extensor hallucis longus muscle can refer pain from GB 36 to the LR line on the foot.

Sustained myofascial dysfunction in the extensor digitorum and hallucis longus muscles can eventually deform the toes, leading to the “classic hammer toe” presentation. In this condition, the metatarsophalangeal joint of all four lesser toes extends while the proximal interphalangeal joint flexes. The distal interphalangeal joint also extends. These abnormal toe positions cause them to resemble “hammer heads”. Wearing tight shoes precipitates the problem; as such, the remedy calls for switching to wide or box-toed shoes and pursuing a course of physical medicine to help undo the damage.

Nerves

- **Lateral sural cutaneous nerve (S1):** A branch of the common peroneal (fibular) nerve that innervates the skin on the lateral part of the caudal crus.
- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus (fibularis) longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot, on their cranial surfaces.
- **Deep peroneal (fibular) nerve (L5-S1):** Innervates the extensor digitorum longus and brevis, the extensor hallucis longus, and the peroneus (fibular) tertius muscles. Innervates the skin of between the first and second digits and metatarsi. Sends articular branches to the joints it crosses.

Clinical Relevance: Several sites of entrapment threaten the common peroneal (fibular) nerve and its branches. The first locus of entrapment involves the common peroneal (fibular) nerve trunk. This occurs at the peroneal (fibular) tunnel – a soft tissue opening between the two heads of the peroneus (fibularis) longus muscle where its two heads attach onto the fibula. Because the lateral sural cutaneous nerve has already branched off of the common peroneal (fibular) nerve by the time the trunk arrives at the tunnel, this entity escapes entrapment. Note the anatomy of these nerves and muscles made apparent in Figure 11-98.

Inside the tunnel proximal to GB 34, the common peroneal (fibular) nerve divides into three nerves: the deep, superficial, and recurrent peroneal (fibular) nerves. All three nerves may undergo traction and compression as they cross the fibular neck. Tension in the soft tissue may force the nerves against the fibular neck, manifesting as impaired sensation, movement, or pain.[3]

Distal to the peroneal (fibular) tunnel, the deep peroneal (fibular) branch follows the ST line while the GB channel accompanies

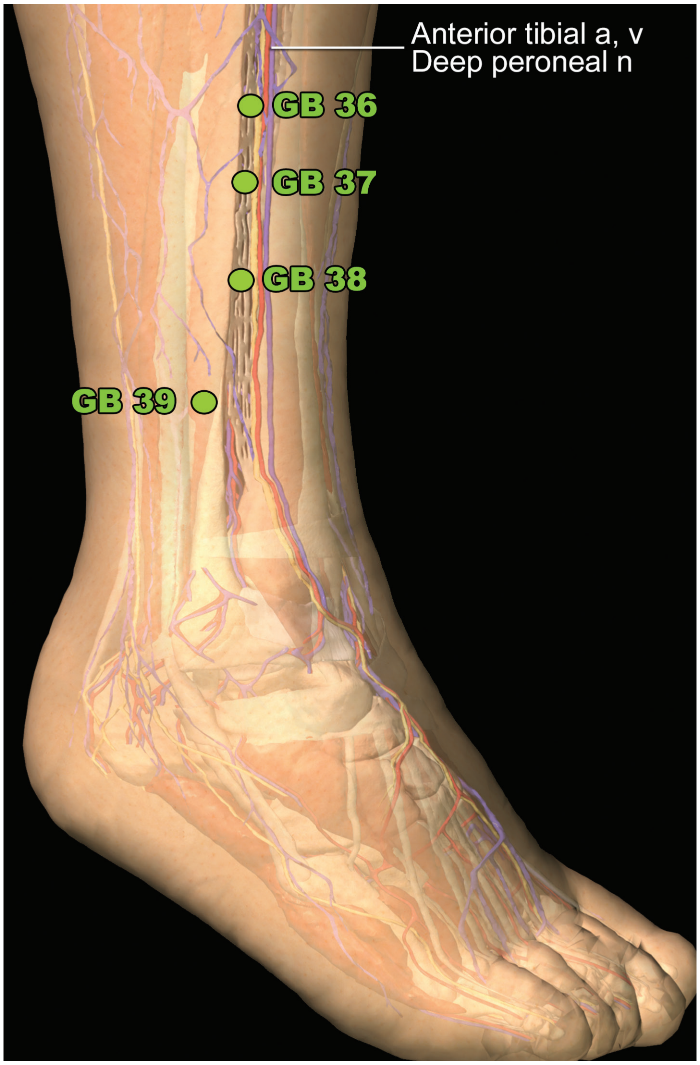

Figure 11-102. This perspective shows how GB 36, GB 37, and GB 38 Line up along the cranial border of the fibula, paralleling the anterior tibial vessels and deep peroneal (fibular) nerve to the ankle. On the dorsum of the foot, this neurovascular bundle then follows the LR line. In actuality, the GB line more closely follows the superficial peroneal (fibular) nerve, not shown.

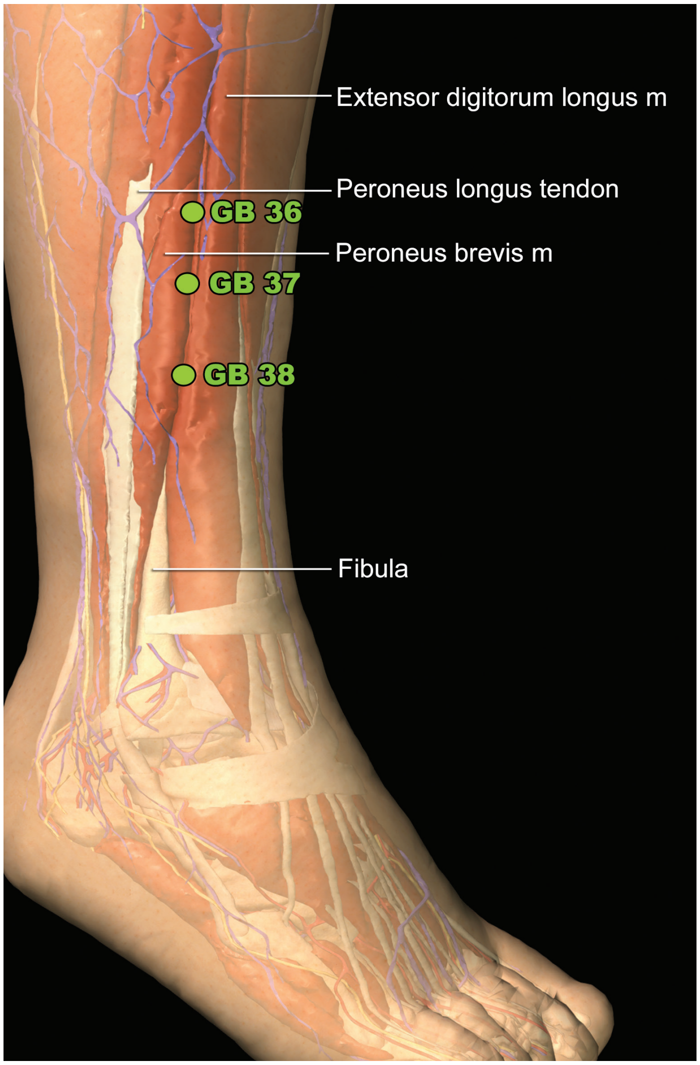

Figure 11-103. GB 36, GB 37, and GB 38 course along the myofascial cleavage plane between the extensor digitorum longus and peroneus (fibularis) brevis muscles. The title "Outer Hill" for GB 36 connotes the mound of muscle on the lateral leg located at the site. This section of the calf contains several points that metaphorically mention landscape, including "Yin Mound Spring" (SP 9), "Leaking Valley" (SP 7), "Yin Valley" (KI 10), "Mountain Support" (BL 57), "Yang Mound Spring" (GB 34), and "Outer Hill" (GB 36).

the superficial peroneal (fibular) nerve branch, following the fibula and peroneus (fibularis) longus muscle to GB 39.

At about the junction of the distal and middle third of the fibula where GB 35, GB 36, and GB 37 lie, the superficial peroneal (fibular) nerve sends a branch to the peroneus (fibularis) brevis muscle. This branch may suffer compression as it makes its way to the brevis between the fibular and peroneus (fibularis) longus muscle.

Compression of the superficial peroneal (fibular) nerve by the crural fascia causes "superficial peroneal (fibular) nerve syndrome". Near GB 37 and GB 38, this nerve emerges through the crural fascia and divides into two cutaneous branches. Fascial restriction may compress the branches as they cross the cranial ankle. If this occurs, sensation may be lessened to the craniolateral distal crus, the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory supply from the deep peroneal (fibular) nerve. (See LR 2 and LR 3.)

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation that follows the GB channel onto the dorsum of the foot, extending to the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer. Nonsurgical approaches that release the nerve and surrounding fascial restriction should be considered prior to surgery.[4]

Typically, nerve entrapment syndromes manifest as burning or "pins and needles" sensations, loss of coordination and proprioception in the limbs, system symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial peroneal (fibular) nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated with resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem. Entrapment of the deep peroneal (fibular) nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis, further distal on the limb.

Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[5]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of sympathetic nervous system activity.[6,7]

Vessels

- **Anterior tibial artery:** Supplies the anterior compartment of the leg.

Clinical Relevance: Arteries such as the anterior tibial artery are vulnerable to damage during surgical procedures such as cutting of the tibia or retracting soft tissues away from the edge of the tibia.[8] Neuromodulation may assist with circulatory benefits and, in the case of laser therapy, angiogenesis and neovascularization.

Indications and Potential Point Combinations

- **Leg pain or cramping, caused by trigger points in the extensor digitorum or hallucis longus muscles, sending pain referred to their respective tendons on the dorsum of the foot:** GB 36, palpably tender trigger points, LR 2, GB 41.
- **Post-thoracotomy pain:** GB 36, GB 34, LI 4, TH 8, local pain and trigger points.
- **Chest wall pain:** GB 36, GB 22, GB 23, pertinent intercostal and/or trigger points affiliated with the dysfunctional or painful region.

Evidence-Based Applications

- Acupuncture at GB 36, BL 40, GB 43, and spinal nerve points from L4-S1 improved signs and symptoms in patients with **prolapsed lumbar intervertebral disk,** possibly in part by improving their IL-6 and hemodynamic profiles.[1]
- Electroacupuncture at GB 36, GB 34, LI 4, and TH 8 significantly reduced the cumulative dose of patient-controlled morphine analgesia accessed by patients on the second postoperative day following **thoracotomy,** compared to patients in receiving sham electroacupuncture.[2]

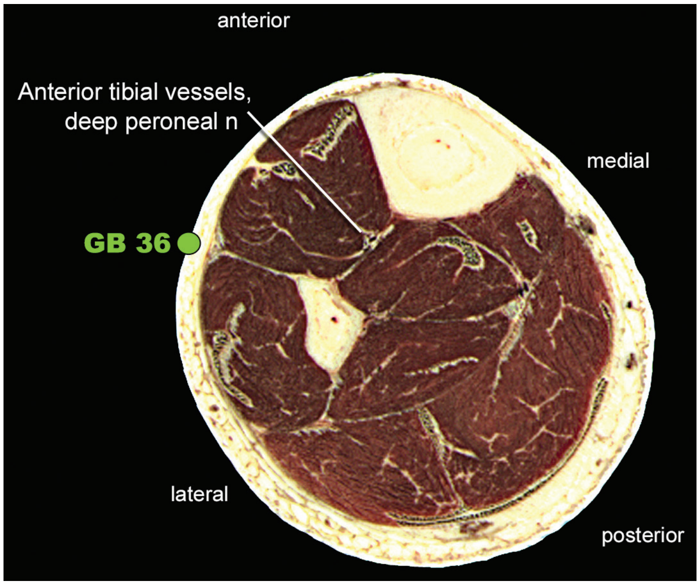

Figure 11-104. Viewing the anatomy deep to GB 36 in cross section exposes the actual distance between the anterior tibial vessels, the deep peroneal (fibular) nerve, and GB 36. As noted above, a closer neural companion to the GB channel than the deep peroneal (fibular) nerve is the superficial peroneal (fibular) nerve.

GB 37

Guang Ming "Bright Light"

On the lateral crus, along the cranial border of the fibula, 5 cun proximal to the most prominent part of the lateral malleolus. Located just proximal to the junction of the middle and lower thirds on a line that connects the tip of the lateral malleolus to the lateral limit of the popliteal crease.

Muscles

- **Peroneus (Fibularis) longus muscle:** Everts the foot and, to a lesser degree, plantarflexes the ankle.
- **Peroneus (Fibularis) brevis muscle:** Everts the foot.
- **Extensor digitorum longus muscle:** Extends the lateral four digits; dorsiflexes the ankle.
- **Extensor hallucis longus muscle:** Extends the great toe and dorsiflexes the ankle.

Clinical Relevance: Taut bands in the peroneus (fibularis) longus muscle can compress the superficial and deep branches of the peroneal (fibularis) nerve, thereby leading to significant problems with foot drop and paresthesias.

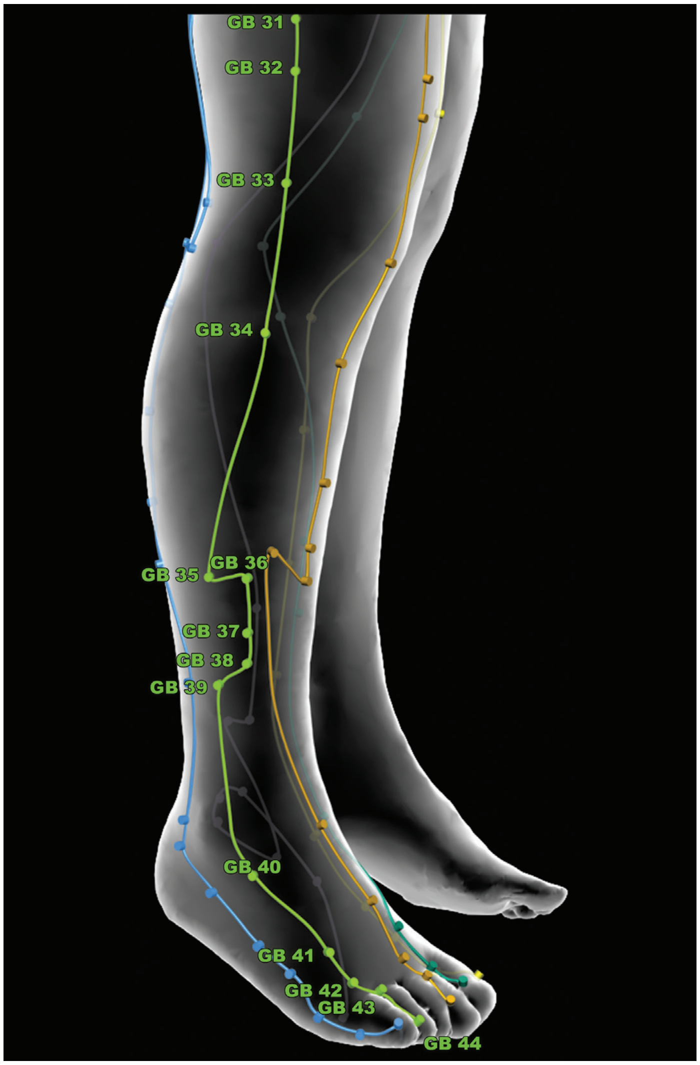

Figure 11-105. One finds GB 37, "Bright Light", either by counting 5 cun proximal to the prominence of the lateral malleolus or by locating it just proximal to the junction of the middle and lower third of the line connecting the tip of the lateral malleolus to the popliteal crease, on the cranial border of the fibula.

Trigger points in the peroneus brevis issue pain along the caudal fibula to the lateral malleolus, then onto the dorsum of the foot toward GB 42.

Trigger points in the peroneal (fibularis) muscles may cause the feeling of having "weak ankles".

Referred pain from extensor digitorum longus trigger points near GB 37 issue pain along the distal GB channel on the dorsum of the foot.

A trigger point in the extensor hallucis longus muscle can refer pain from GB 37 to the LR line on the foot.

Sustained myofascial dysfunction in the extensor digitorum and hallucis longus muscles can eventually deform the toes, leading to the "classic hammer toe" presentation. In this condition, the metatarsophalangeal joint of all four lesser toes extends while the proximal interphalangeal joint flexes. The distal interphalangeal joint also extends. These abnormal toe positions cause them to resemble "hammer heads". Wearing tight shoes precipitates the problem; as such, the remedy calls for switching to wide or box-toed shoes and pursuing a course of physical medicine to help undo the damage.

Nerves

- **Lateral sural cutaneous nerve (S1):** A branch of the common peroneal (fibular) nerve that innervates the skin on the lateral part of the caudal crus.
- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus (fibularis) longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot, on their cranial surfaces.
- **Deep peroneal (fibular) nerve (L5-S1):** Innervates the extensor digitorum longus and brevis, the extensor hallucis longus, and the peroneus (fibular) tertius muscles. Innervates the skin of between the first and second digits and metatarsi. Sends articular branches to the joints it crosses.

Clinical Relevance: Several sites of entrapment threaten the common peroneal (fibular) nerve and its branches. The first locus of entrapment involves the common peroneal (fibular) nerve trunk. This occurs at the peroneal (fibular) tunnel – a soft tissue opening between the two heads of the peroneus (fibularis) longus muscle where its two heads attach onto the fibula. Because the lateral sural cutaneous nerve has already branched off of the common peroneal (fibular) nerve by the time the trunk arrives at the tunnel, this entity escapes entrapment. Note the anatomy of these nerves and muscles made apparent in Figure 11-98.

Inside the tunnel proximal to GB 34, the common peroneal (fibular) nerve divides into three nerves: the deep, superficial, and recurrent peroneal (fibular) nerves. All three nerves may undergo traction and compression as they cross the fibular neck. Tension in the soft tissue may force the nerves against the fibular neck, manifesting as impaired sensation, movement, or pain.[9]

Distal to the peroneal (fibular) tunnel, the deep peroneal (fibular) branch follows the ST line while the GB channel accompanies the superficial peroneal (fibular) nerve branch, following the fibula and peroneus (fibularis) longus muscle to GB 39.

At about the junction of the distal and middle third of the fibula where GB 35, GB 36, and GB 37 lie, the superficial peroneal (fibular) nerve sends a branch to the peroneus (fibularis) brevis muscle. This branch may suffer compression as it makes its way to the brevis between the fibular and peroneus (fibularis) longus muscle.

Compression of the superficial peroneal (fibular) nerve by the crural fascia causes "superficial peroneal (fibular) nerve syndrome". Near GB 37 and GB 38, this nerve emerges through the crural fascia and divides into two cutaneous branches. Fascial restriction may compress the branches as they cross the cranial ankle. If this occurs, sensation may be lessened to the craniolateral distal crus, the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory supply from the deep peroneal (fibular) nerve. (See LR 2 and LR 3.)

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation that follows the GB channel onto the dorsum of the foot, extending to the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer. Nonsurgical approaches that release the nerve and surrounding fascial restriction should be considered prior to surgery.[10]

Typically, nerve entrapment syndromes manifest as burning or "pins and needles" sensations, loss of coordination and proprioception in the limbs, system symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial peroneal (fibular) nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated with resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem. Entrapment of the deep peroneal (fibular) nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis, further distal on the limb.

Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[11]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of sympathetic nervous system activity.[12,13]

Vessels

- **Anterior tibial artery:** Supplies the anterior compartment of the leg.

Clinical Relevance: Arteries such as the anterior tibial artery are vulnerable to damage during surgical procedures such as cutting of the tibia or retracting soft tissues away from the edge of the tibia.[14] Neuromodulation may assist with circulatory benefits and, in the case of laser therapy, angiogenesis and neovascularization.

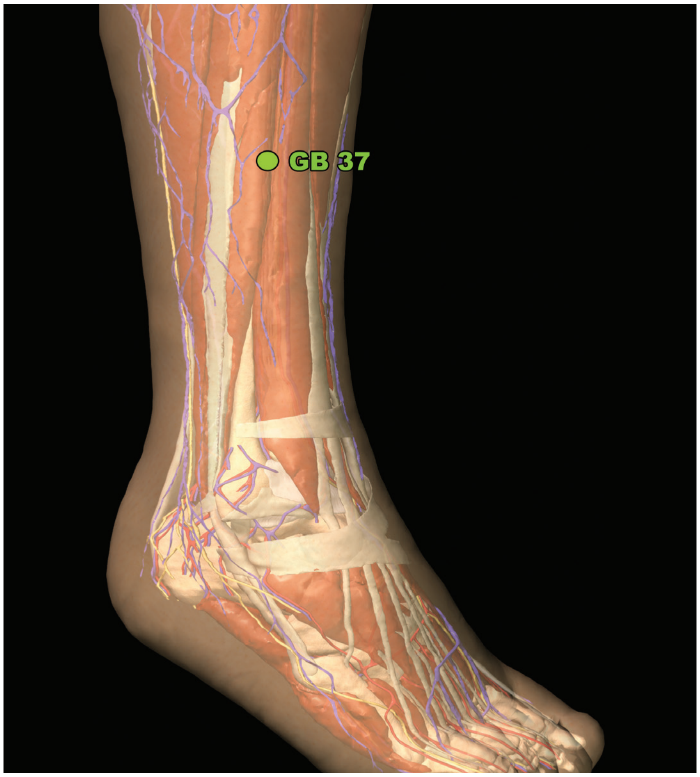

Figure 11-106. The descriptive name for GB 37, "Bright Light" connotes its indication for visual disturbances. This connection inspired researchers in brain imaging to investigate its effects on the brain and especially on centers that process visual information. However, whether GB 37 is unique in this regard is unclear and requires further research. It may be that several points on the lateral crus similarly influence visual processing and stimulate posterior cerebral artery blood flow.

Indications and Potential Point Combinations

- **Pain at the dorsum of the foot:** GB 37, other local trigger points referring pain to the toes.
- **Eye disorders, diminished vision, adjunctive treatment for glaucoma:** GB 37, LI 4, LR 3, BL 60.

Evidence-Based Applications

- Acupuncture stimulation of GB 37 failed to activate the visual cortex on functional magnetic resonance imaging, unlike BL 67, which has been demonstrated to do so, although GB 37 has **vision-related applications.** Strength and type of stimulation may be a factor in brain activation results.[1]
- Blood oxygen-level-dependent signal decreases in the occipital cortex of the brain, evoked by electroacupuncture, occurred in a similar fashion when both **"vision points"**, GB 37 and BL 60, were stimulated, as well as an adjacent non-acupuncture point.[2,3] Although the points themselves may lack specificity, the connection between them and their impact on brain function likely stems from their common neurologic supply; i.e., branches of the peroneal nerve.
- Acupuncture at GB 37 and LR 3 produced changes in blood oxygen saturation levels in certain brain regions, though not in the **visual cortex,** with either visual stimulation or needle stimulation, causing one to question whether the study design is crucial in picking up these changes.[4] Another experiment

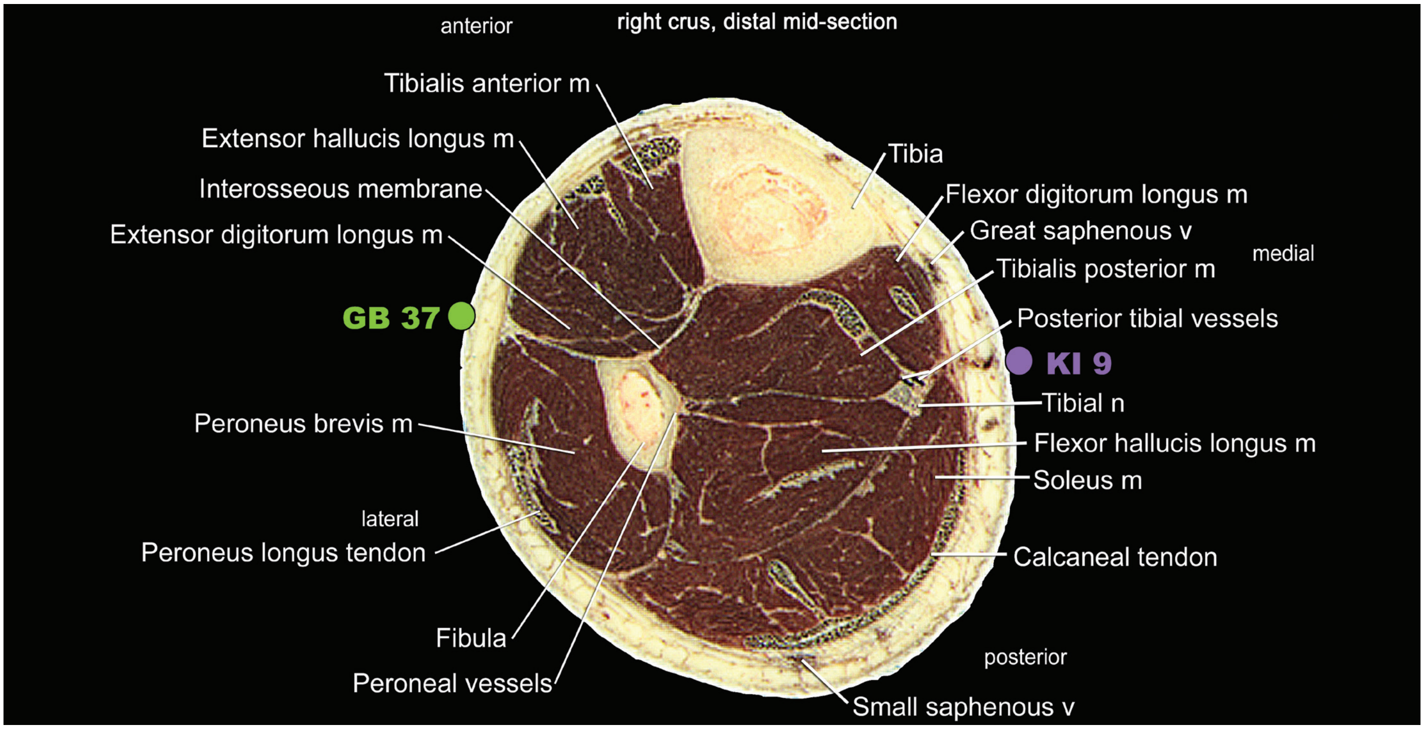

Figure 11-107. Like its GB point compatriots along the mid-crus, GB 37 is perfectly situated to address myofascial trigger points in either the extensor digitorum longus or the peroneus (fibularis) brevis muscle, depending on the angle and depth of needle insertion.

involving electroacupuncture at GB 37 compared to KI 8 showed that both points produced strong activation in the visual cortical regions BA 17/18/19 and that they were modulated in opposite directions during the resting state following acupuncture.[5] Given that GB 37 is supplied by the peroneal nerve primarily, and KI 8 by the tibial, the Complementarity of temporal modulation but similarity of spatial distribution parallels the impression that each point sits on opposite aspects of the leg, but originate from the same nerve, i.e., the sciatic.

- Acupuncture at GB 37, ST 40, and ST 43 did not affect the visual cortex, but did impact the insula sulcus lateralis and the parieto-temporal cortex, areas involved in **processing painful and/or somatosensory input.**[6]
- Acupuncture at GB 37 induced **complex brain activity in the visual cortex.**[15]
- Electroacupuncture at GB 37, LI 4, and LR 3 significantly **reduced intraocular pressure** in both eyes in isoflurane-anesthetized and normal dogs.[7,8]
- Laser stimulation of GB 37, LR 3, and BL 67 produced significant increases in blood flow velocity through the **posterior cerebral artery** and not the anterior cerebral artery, perhaps linking these points more specifically to the visual system in the brain.[16] In contrast LI 4, LI 6, and LI 20 significantly increased blood flow velocity in the anterior cerebral artery but not the posterior cerebral artery.
- Manual acupuncture at GB 37 may help reduce the pain of **panretinal photocoagulation.**[17]

GB 38

Yang Fu "Yang Assistance"

On the lateral crus, along the cranial border of the fibula, 4 cun proximal to the most prominent part of the lateral malleolus. Located at the junction of the upper three-fourths and lower one-fourth of the line connecting the tip of the lateral malleolus to the lateral limit of the popliteal crease.

Muscles

- **Peroneus (Fibularis) longus muscle:** Everts the foot and, to a lesser degree, plantarflexes the ankle.
- **Peroneus (Fibularis) brevis muscle:** Everts the foot.
- **Peroneus (Fibularis) tertius muscle:** The peroneus tertius differs from the peroneus longus and brevis muscles both anatomically and functionally. Whereas the peroneus longus and brevis course behind the lateral malleolus, the peroneus tertius tendon courses over the cranial aspect of the malleolus. Its tendon actually anchors onto three locations: the tubercle of the 5th metatarsal, the mediodorsal surface of the 5th metatarsal, and the base of the 4th metatarsal. These insertions spiral and tighten during passive inversion of the foot; they lengthen, straighten, and relax when the foot passively everts.
- **Extensor digitorum longus muscle:** Extends the lateral four digits; dorsiflexes the ankle.
- **Extensor hallucis longus muscle:** Extends the great toe and dorsiflexes the ankle.

Clinical Relevance: Taut bands in the peroneus (fibularis) longus muscle can compress the superficial and deep branches of the peroneal (fibularis) nerve, thereby leading to significant problems with foot drop and paresthesias.

Trigger points in the peroneus brevis issue pain along the caudal fibula to the lateral malleolus, then onto the dorsum of the foot toward GB 42.

Trigger points in the peroneal (fibularis) muscles may cause the feeling of having "weak ankles".

Peroneus tertius trigger points at GB 38 and a bit more distal send pain to the dorsolateral ankle and foot, following the GB and ST lines to the toes. Another segment of pain from a dysfunctional peroneus tertius projects to the lateral calcaneal tendon and heel, from BL 60 to BL 62. The peroneus longus and brevis receive motor function from the superficial peroneal (fibular) nerve (L4, L5, S1) while the peroneus tertius is innervated by the deep peroneal (fibular) nerve (L5, S1). The peroneus tertius occupies the cranial compartment of the crus while the peroneus longus and brevis live on the lateral leg.

Referred pain from extensor digitorum longus trigger points near GB 38 issue pain along the distal GB channel on the dorsum of the foot.

A trigger point in the extensor hallucis longus muscle can refer pain from GB 38 to the LR line on the foot.

Sustained myofascial dysfunction in the extensor digitorum and hallucis longus muscles can eventually deform the toes, leading to the "classic hammer toe" presentation. In this condition, the metatarsophalangeal joint of all four lesser toes extends while the proximal interphalangeal joint flexes. The distal interphalangeal joint also extends. These abnormal toe positions cause them to resemble "hammer heads". Wearing tight shoes precipitates the problem; as such, the remedy calls for switching to wide or box-toed shoes and pursuing a course of physical medicine to help undo the damage.

Nerves

- **Lateral sural cutaneous nerve (S1):** A branch of the common peroneal (fibular) nerve that innervates the skin on the lateral part of the caudal crus.
- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus (fibularis) longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot, on their cranial surfaces.
- **Deep peroneal (fibular) nerve (L5-S1):** Innervates the extensor digitorum longus and brevis, the extensor hallucis longus, and the peroneus (fibular) tertius muscles. Innervates the skin of between the first and second digits and metatarsi. Sends articular branches to the joints it crosses.

Clinical Relevance: Several sites of entrapment threaten the common peroneal (fibular) nerve and its branches. The first locus of entrapment involves the common peroneal (fibular) nerve

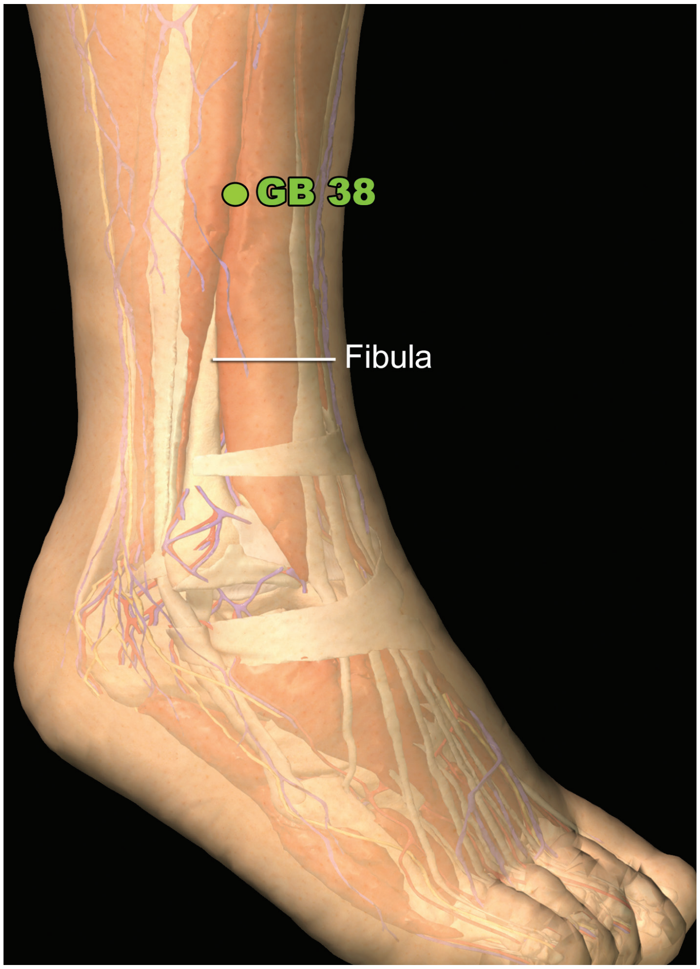

Figure 11-108. GB 38, "Yang Assistance" refers to the support provided by the fibula to the lower limb. The Chinese term "Fu" in "Yang Fu" connotes a pole attached to a cart to keep it from tipping.[7] Note how the fibula here pokes through the cleft between the peroneal (fibularis) and long digital extensor muscles.

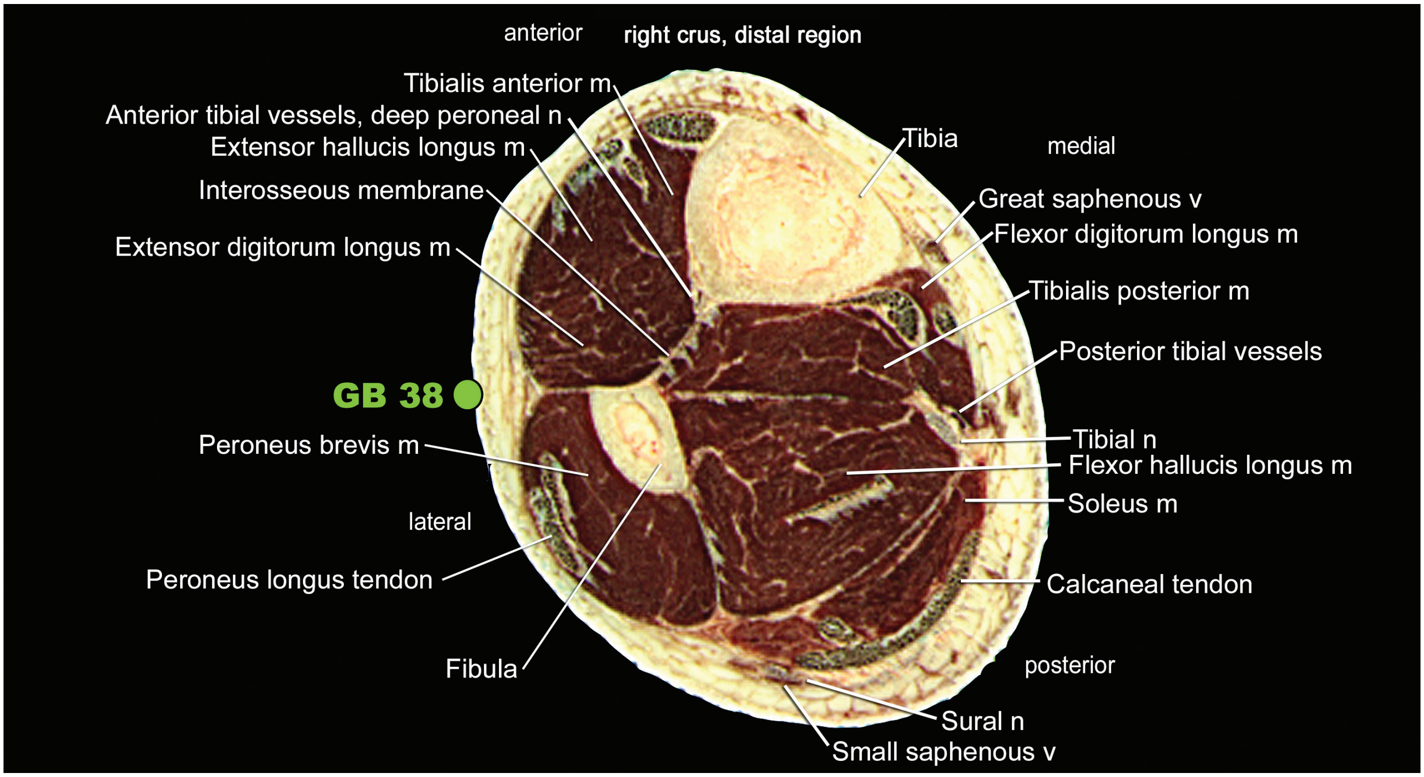

Figure 11-109. The fibula is becoming more superficial at GB 38. The peroneus tertius, discussed earlier, does not appear in this cross section, and is not present in all individuals. The three peroneal muscles are variable, with some individuals having a peroneus quartus and/or a peroneus (fibularis) digiti minimi muscle.

trunk. This occurs at the peroneal (fibular) tunnel – a soft tissue opening between the two heads of the peroneus (fibularis) longus muscle where its two heads attach onto the fibula. Because the lateral sural cutaneous nerve has already branched off of the common peroneal (fibular) nerve by the time the trunk arrives at the tunnel, this entity escapes entrapment. Note the anatomy of these nerves and muscles made apparent in Figure 11-98.

Inside the tunnel proximal to GB 34, the common peroneal (fibular) nerve divides into three nerves: the deep, superficial, and recurrent peroneal (fibular) nerves. All three nerves may undergo traction and compression as they cross the fibular neck. Tension in the soft tissue may force the nerves against the fibular neck, manifesting as impaired sensation, movement, or pain.[1]

Distal to the peroneal (fibular) tunnel, the deep peroneal (fibular) branch follows the ST line while the GB channel accompanies the superficial peroneal (fibular) nerve branch, following the fibula and peroneus (fibularis) longus muscle to GB 39.

At about the junction of the distal and middle third of the fibula where GB 35, GB 36, and GB 37 lie, the superficial peroneal (fibular) nerve sends a branch to the peroneus (fibularis) brevis muscle. This branch may suffer compression as it makes its way to the brevis between the fibular and peroneus (fibularis) longus muscle.

Compression of the superficial peroneal (fibular) nerve by the crural fascia causes “superficial peroneal (fibular) nerve syndrome”. Near GB 37 and GB 38, this nerve emerges through the crural fascia and divides into two cutaneous branches. Fascial restriction may compress the branches as they cross the cranial ankle. If this occurs, sensation may be lessened to the craniolateral distal crus, the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory supply from the deep peroneal (fibular) nerve. (See LR 2 and LR 3.)

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation that follows the GB channel onto the dorsum of the foot, extending to the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer. Nonsurgical approaches that release the nerve and surrounding fascial restriction should be considered prior to surgery.[2]

Typically, nerve entrapment syndromes manifest as burning or “pins and needles” sensations, loss of coordination and proprioception in the limbs, system symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial peroneal (fibular) nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated with resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem. Entrapment of the deep peroneal (fibular) nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis, further distal on the limb.

Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[3]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of sympathetic nervous system activity.[4,5]

Vessels

- **Anterior tibial artery:** Supplies the cranial compartment of the crus.

Clinical Relevance: Arteries such as the anterior tibial artery are vulnerable to damage during surgical procedures such as cutting of the tibia or retracting soft tissues away from the edge of the tibia.[6] Neuromodulation may assist with circulatory benefits and, in the case of laser therapy, angiogenesis and neovascularization.

Indications and Potential Point Combinations

- **Feeling of weakness in the ankles:** GB 38, other pertinent trigger points. Evaluate the peroneus longus, brevis, and tertius closely for myofascial tenderness and trigger points.
- **Foot drop:** GB 38, LR 2, ST 36, Bafeng (at the web spaces between the toes).

GB 39

Xuan Zhong "Suspended Bell" or, less commonly, Jue Gu "Severed Bone"

On the lateral crus, 3 cun proximal to the most prominent part of the lateral malleolus, in a depression between the caudal border of the fibula and the peroneus (fibularis) longus and brevis muscles/tendons. Some authors place GB 39 between the two tendons. Ask the patient to wiggle the ankle to differentiate the two tendons on the lateral aspect of the leg if targeting the latter location. Review the relationship of the peroneal (fibular) myotendinous structures and the fibula in Figure 11-110.

Muscles

- **Peroneus (Fibularis) longus muscle:** Everts the foot and, to a lesser degree, plantarflexes the ankle.
- **Peroneus (Fibularis) brevis muscle:** Everts the foot.

Clinical Relevance: Taut bands in the peroneus (fibularis) longus muscle can compress the superficial and deep branches of the peroneal (fibularis) nerve, leading to significant problems with foot drop and paresthesias.

Trigger points in the peroneus brevis issue pain along the caudal fibula to the lateral malleolus, then onto the dorsum of the foot toward GB 42.

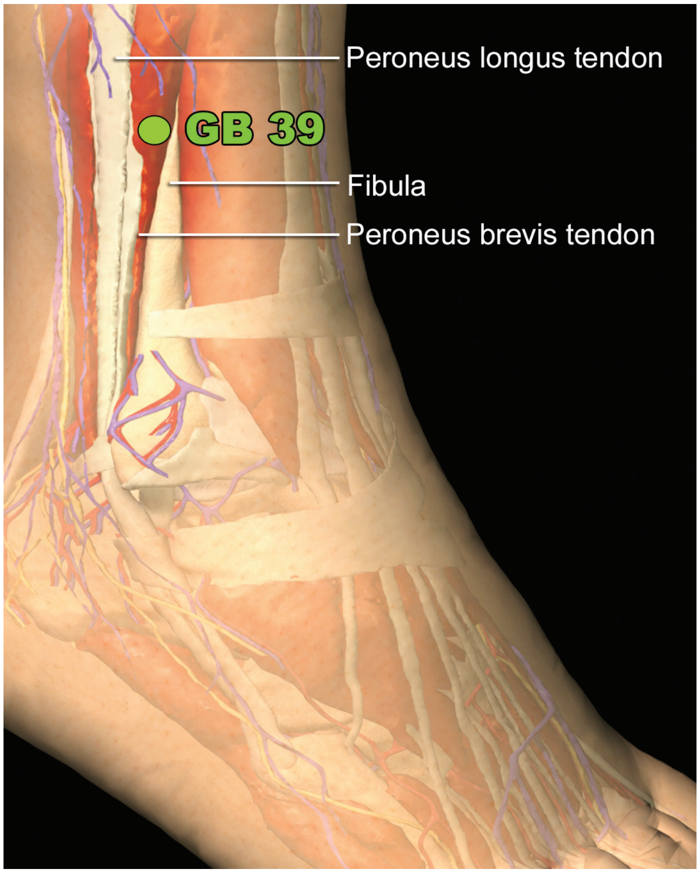

Figure 11-110. The descriptive title for GB 39, i.e., "Suspended Bell", has two connotations. Firstly, the lateral malleolus flares like a bell suspended from the fibula at GB 39. Secondly, children in parts of ancient China wore bells around their ankles.

Trigger points in the peroneal (fibularis) muscles may cause the feeling of having "weak ankles".

Nerves

- **Lateral sural cutaneous nerve (S1):** A branch of the common peroneal (fibular) nerve that innervates the skin on the lateral crus.
- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus (fibularis) longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot, on their dorsal surfaces.

Clinical Relevance: Several sites of entrapment threaten the common peroneal (fibular) nerve and its branches. The first locus involves the common peroneal (fibular) nerve trunk. This occurs at the peroneal (fibular) tunnel – a soft tissue opening between the two heads of the peroneus (fibularis) longus muscle where they attach onto the fibula. Because the lateral sural cutaneous nerve has already branched off of the common peroneal (fibular) nerve by the time the trunk arrives at the tunnel, this nerve escapes entrapment. Note the anatomy of these nerves and muscles made apparent in Figure 11-98.

Inside the tunnel proximal to GB 34, the common peroneal (fibular) nerve divides into three nerves: the deep, superficial, and recurrent peroneal (fibular) nerves. All three may undergo traction and compression as they cross the fibular neck. Tension in the soft tissue forces the nerves against the fibular neck, manifesting as impaired sensation, movement, or pain.[4]

Distal to the peroneal (fibular) tunnel, the deep peroneal (fibular) branch follows the ST line while the GB channel accompanies the superficial peroneal (fibular) nerve branch, following the fibula and peroneus (fibularis) longus muscle to GB 39.

At about the junction of the distal and middle third of the fibula where GB 35, GB 36, and GB 37 appear, the superficial peroneal (fibular) nerve sends a branch to the peroneus (fibularis) brevis muscle. This branch may suffer compression as it makes its way to the brevis between the fibular and peroneus (fibularis) longus muscle.

Compression of the superficial peroneal (fibular) nerve by crural fascia causes "superficial peroneal (fibular) nerve syndrome". Near GB 39, this nerve emerges through the crural fascia and divides into two cutaneous branches, the medial dorsal and intermediate dorsal cutaneous nerves. The intermediate dorsal cutaneous nerve follows the GB channel to the toes while the medial dorsal cutaneous nerve accompanies the ST channel. The LR channel on the dorsum of the foot (from about LR 1-LR 3) receives sensation by the lateral branch of the deep peroneal (fibular) nerve but may include some fibers from the intermediate dorsal cutaneous nerve from superficial peroneal (fibular) origin.[5]

Fascial restriction can compress cutaneous branches as they cross the cranial ankle. If this occurs, sensation may be lessened to the craniolateral distal crus, the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory supply from the deep peroneal (fibular) nerve.

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation along the GB channel on the distal, lateral crus and dorsum of the foot that extends to the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer. Nonsurgical approaches that release the nerve and surrounding fascial restriction should be considered prior to surgery.[6]

Typically, nerve entrapment syndromes manifest as burning or "pins and needles" sensations, loss of coordination and proprioception in the limbs, symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial peroneal (fibular) nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated by resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem.

Distal entrapment of the deep peroneal (fibular) nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis, further distal on the limb.

Compression at GB 39 affects the superficial peroneal (fibular) nerve where it branches into the medial and intermediate dorsal cutaneous nerves. Anatomically, the superficial peroneal (fibular) nerve exits from deep fascia here. A fascial edge may impinge on the nerve, as may muscle that has herniated through fascial defects.[7] The superficial peroneal (fibular) nerve courses along a short fibrous tunnel located between the anterior intermuscular septum and the fascia of the lateral compartment. Patients with nerve entrapment at this location may be considered to exhibit a local compartment syndrome.

Chronic ankle instability and sprain reinjures the nerve and predisposes individuals to develop a fibrotic, low compliant nature to this tunnel. Surgery may also cause problems, as it may shift the fascia following anterior compartment fasciotomy and place added stretch on the nerve. Iatrogenic injuries to the common peroneal (fibular) nerve and its branches stem from procedures that take a lateral or craniolateral approach to the knee, ankle, fibular, or soft tissue. A fracture of the fibular head may lacerate or compress one or more nerve branches and manifest as sensory and/or motor loss of varying degrees. Inflammation and edema after trauma may injure nerves as well.

Patients experiencing superficial peroneal (fibular) nerve entrapment at GB 39 complain of pain on the craniolateral calf and dorsum of the ankle and foot. Pain often lasts for years and recurs intermittently. About a third of patients report sensory changes along the distribution of the nerve, in the form of numbness or paresthesias. Activities such as running, squatting, jogging, or even walking worsen the problem. Focused palpation along the entire GB channel from GB 34 to GB 40 as well as the entire pelvic limb should provide insight into the source of myofascial dysfunction and the sites to needle or otherwise neuromodulate.

Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[8]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of sympathetic nervous system activity.[9,10]

Vessels

- **Peroneal (fibular) artery:** The largest and most important branch of the tibial artery. Provides muscular branches to the popliteus and other muscles occupying the posterior and lateral compartments of the leg. Supplies a nutrient artery to the fibula.

Clinical Relevance: Ankle injuries involving the tibiofibular syndesmosis raise the likelihood of producing prolonged ankle discomfort and disability.[11] In part, this is due to the possible disruption of the primary vascular supply to cranial ankle ligaments, i.e., the peroneal (fibular) artery at its perforating branch.

Indications and Potential Point Combinations

- **Lateral ankle pain:** GB 39, GB 35, assess for additional trigger points.
- **"Weak ankles":** GB 39, other GB points on the crus, SP 6, GB 40, strengthening therapeutic exercise, laser therapy, massage.
- **Knee pain:** GB 34, GB 39, SP 6, SP 9, ST 35, ST 36, KI 3, and Xiyan

Evidence-Based Applications

- Uncontrolled study showed GB 39 effective for **treating costal chondritis.**[1]
- Acupuncture was shown to be an effective and safe adjunctive therapy for patients with **knee osteoarthritis,** using the following points: GB 34, GB 39, SP 6, SP 9, ST 35, ST 36, KI 3, and Xiyan.[2]
- Electroacupuncture at Neixiyan, Waixiyan, GB 39, and KI 3 alleviated symptoms of **knee osteoarthritis** better than did hyaluronic acid injection. Electroacupuncture also suppressed secretion of interleukin-1, interleukin-6, tumor necrosis factor-alpha, prostaglandin E-2 alpha, and matrix metalloproteinase 3 in synovial fluid of the knee.[12]
- Acupuncture at GB 39 for postoperative **orthopedic pain** and ashi (local painful) points provided comparable analgesia to medication (Bezoxazocine i.m.).[3]
- Deep needling of GB 34 and GB 39 modulated sympathetic activity in patients with **pelvic limb pain.**[13]
- Although GB 39 receives attention clinically as one of the Hui, or Influential points that specifically affects **marrow**, it is difficult to find any anatomic justification or evidential support for this contention.[14] Furthermore, Chinese clinicians of today as well past generations rarely use this point for marrow disorders, emphasizing its misnaming as an influential point for marrow.
- Electroacupuncture at SP 6 immediately alleviated **menstrual pain** while GB 39 does not. This may reflect the differing innervation of the two points (tibial versus peroneal (fibular) nerve) arising from different spinal cord segments.[15] However, others disputed these findings.[16]

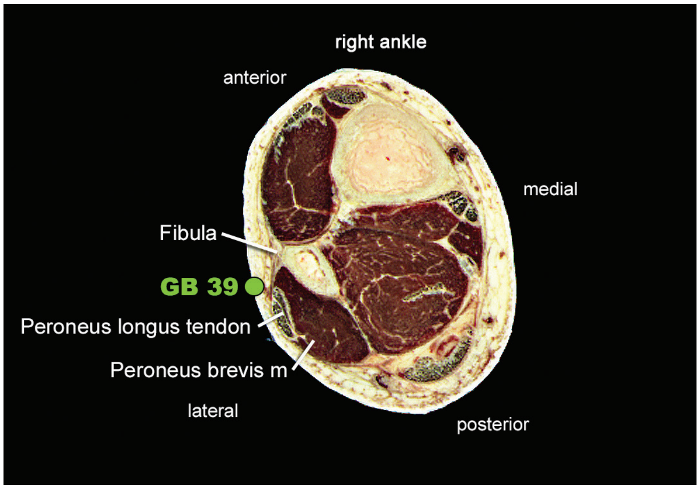

Figure 11-111. This cross section illustrates the close connections made by the fibula and the two peroneus tendons in the vicinity of GB 39. One can imagine the tight quarters that the superficial peroneal (fibular) nerve must navigate as its cutaneous branches make their way through dense and tense fascial structures to subcutaneous levels.

GB 40

Qiu Xu "Mound of Ruins"

In a large depression anterior and inferior to the lateral malleolus, just lateral to the extensor digitorum longus tendon, at the entrance to the sinus tarsi. Locate at the intersection of lines drawn from the anterior and inferior borders of the lateral malleolus. Easier to locate with foot slightly supinated.

Connective Tissues

- **Interosseous talocalcaneal ligament in the sinus tarsi:** Supports the subtalar joint, which is where the talus rests on the calcaneus and forms an articulation. It is here that most of the inverting and everting movements of the ankle occur.
- **Inferior extensor retinaculum:** This Y-shaped strap of flat and thick connective tissue crosses the proximal aspect of the foot. The stem of this Y, located beneath GB 40, encloses the long extensor tendons in between its superficial and deep laminae.[1]

Clinical Relevance: While the medial root of the retinaculum attaches to the calcaneus just anterior to the location of talocalcaneal ligament attachment, the lateral root of the inferior extensor retinaculum attaches to the calcaneus in the vicinity of GB 40, at the external aspect of the tarsal sinus. Following foot trauma, a dysfunctional retinaculum may produce peroneal nerve entrapment.[2]

Chronic craniolateral ankle pain and snapping on ankle inversion may be due to trauma or the consequences of trauma, wherein tissue changes in the region around GB 40 produce various problems. These include proliferative synovitis, peroneal (fibularis) tendon instability, or abnormalities in the anteriorinferior tibiofibular ligament over the lateral talar dome.[6] Atraumatic conditions responsible for craniolateral ankle pain and snapping include osteochondral lesions, arthritis, presence of a peroneus (fibularis) tertius muscle, and loose bodies in the joint.

Bony Features

- **Sinus tarsi (Tarsal sinus, or talocalcaneal sulcus):** A canal, or hollow, created where the groove of the talus meets the interosseous groove of the calcaneus. It is here where the interosseous talocalcaneal ligament can be found. Although Figure 11-112 only indicates space in the tarsal sinus, it actually contains a number of structures such as fat, an arterial anastomosis, nerve endings, joint capsules, and five ligaments. These ligaments include the medial, intermediate, and lateral roots of the inferior extensor retinaculum, the cervical ligament, and the ligament of the tarsal canal, also known as the interosseous talocalcaneal ligament.[7]

Clinical Relevance: Ankle biomechanics involve more than simple flexion-extension motions. Its characteristics include subtalar joint mechanics that allow the foot to adapt to the surface of the ground.[8] The subtalar ligaments associated with the sinus tarsi provide ankle stability by means of the cervical and interosseous calcaneal interosseous ligament.

Surgeries designed to stabilize the ankle and reconstruct ligamentous support may fail due to inadequate correction of the complex pathomechanics of ankle instability.

Overly tightened ankle ligaments may impair proprioceptive reflexes. As such, physical medicine maneuvers may be indicated in order to improve soft tissue mechanics, proprioceptive support, and improve postural balance.

Sinus tarsi syndrome occurs between the calcaneus, talus, and talocalcaneonavicular and subtalar joints. Symptoms include lateral midfoot heel pain or pain in the lateral calcaneus and ankle. Pain worsens following exercise as well as when walking on an uneven surface. Repeated sprain of the lateral ankle as well as chronic hyperpronation of the foot predisposes individuals to developing sinus tarsi syndrome.[9] Usual recommended treatments include orthotics, physical therapy, and injections at GB 40; anti-inflammatory and analgesic drugs may be beneficial. However, acupuncture and laser therapy may lessen pain and improve function in ways that allopathic treatments do not.

Nerves

- **Sural nerve:** Most commonly arises from the union of the medial sural cutaneous branch of the tibial nerve (L4-S3) and the sural communicating branch of the common peroneal (fibular) nerve (L4-S2). Innervates the lateral aspect of the foot. Courses caudal to the lateral malleolus, accompanying the small saphenous vein. Provides lateral calcaneal branches and terminates as the dorsal lateral cutaneous nerve of the foot.
- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot and all digits, except for the lateral side of the 5th pedal digit and the adjoining sides of the 1st and 2nd digits (which receives innervation from the deep peroneal nerve). Forms the dorsal digital nerves.

Clinical Relevance: Certain afferent nerve neuromodulation techniques stimulate the sural nerve in order to treat voiding dysfunction, making use of the overlapping spinal cord of

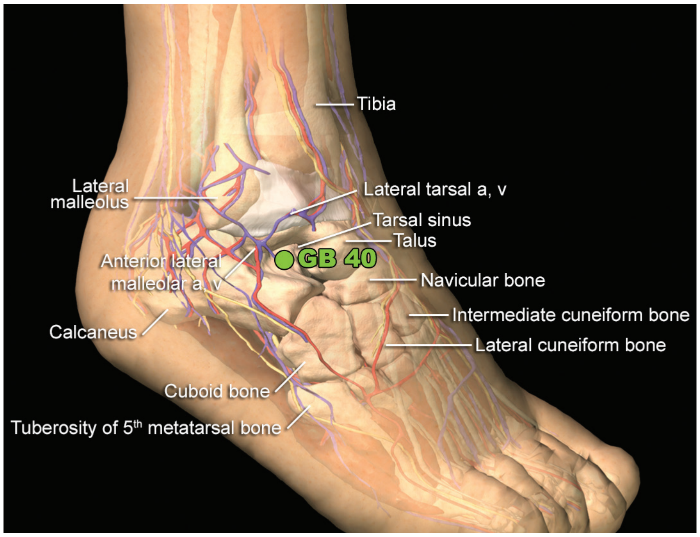

Figure 11-112. GB 40, "Mound of Ruins" connotes a pile of rubble at the bottom of a hill, strongly evocative of the tarsal bones lying below the ankle joint. The specific indication of GB 40 for sinus tarsi syndrome becomes clear based on the anatomy. One or more structures within the tarsal sinus and canal can cause pain and a feeling of instability in the ankle. Although not shown in this figure, the interosseous talocalcaneal ligament extends from the calcaneus to the talus and maintains apposition of the talus tali and the sulcus calcaneus. Injury to this and other connective tissue structures influencing the tarsal sinus may accompany ankle sprain.[24]

segments supplying both the pelvic limb and pelvic viscera.[3]

The fascial sheath surrounding the caudal calf muscles will at times entrap the sural nerve as it emerges near BL 58. At the ankle, branches of the sural nerve can also experience compression. Heel pain accompanied by tingling, burning, or loss of sensation suggest neuropathic injury by compression, traction, or other causes.[10]

From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[11] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-121B) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Lateral heel pain from lateral calcaneal neuritis (branches of the sural nerve) produces discomfort that radiates along the nerve, although the pain may be difficult to localize in some cases. This contrasts with calcaneal stress fracture that leads to pain over the entire calcaneus or peroneal (fibularis) tendon disorders that cause pain on the lateral calcaneus and peroneal tubercle.

Several sites of entrapment threaten the common peroneal (fibular) nerve and its branches. The first locus involves the common peroneal (fibular) nerve trunk. This occurs at the peroneal (fibular) tunnel – a soft tissue opening between the two heads of the peroneus (fibularis) longus muscle where they attach onto the fibula. Because the lateral sural cutaneous nerve has already branched off of the common peroneal (fibular) nerve by the time the trunk arrives at the tunnel, this nerve escapes entrapment. Note the anatomy of these nerves and muscles made apparent in Figure 11-98.

Inside the peroneal (fibularis) tunnel proximal to GB 34, the common peroneal (fibular) nerve divides into three nerves: the deep, superficial, and recurrent peroneal (fibular) nerves. All three may undergo traction and compression as they cross the fibular neck. Tension in the soft tissue forces the nerves against the fibular neck, manifesting as impaired sensation, movement, or pain.[12]

Distal to the peroneal (fibular) tunnel, the deep peroneal (fibular) branch follows the ST line while the GB channel accompanies the superficial peroneal (fibular) nerve branch, following the fibula and peroneus (fibularis) longus muscle to GB 39.

At about the junction of the distal and middle third of the fibula where GB 35, GB 36, and GB 37 fall, the superficial peroneal (fibular) nerve sends a branch to the peroneus (fibularis) brevis muscle. This branch may suffer compression as it makes its way to the brevis between the fibular and peroneus (fibularis) longus muscle.

Compression of the superficial peroneal (fibular) nerve by crural fascia causes “superficial peroneal (fibular) nerve syndrome”. Near GB 39, this nerve emerges through the crural fascia and divides into two cutaneous branches, the medial dorsal and intermediate dorsal cutaneous nerves. The intermediate dorsal cutaneous nerve follows the GB channel to GB 40 and the toes while the medial dorsal cutaneous nerve accompanies the ST channel. The LR channel on the dorsum of the foot (from about LR 1-LR 3) receives sensation by the lateral branch of the deep peroneal (fibular) nerve but may include some fibers from the intermediate dorsal cutaneous nerve from superficial peroneal (fibular) origin.[13]

Fascial restriction can compress cutaneous branches as they cross the cranial ankle. If this occurs, sensation may be lessened to the craniolateral distal crus and ankle (GB 40), the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory

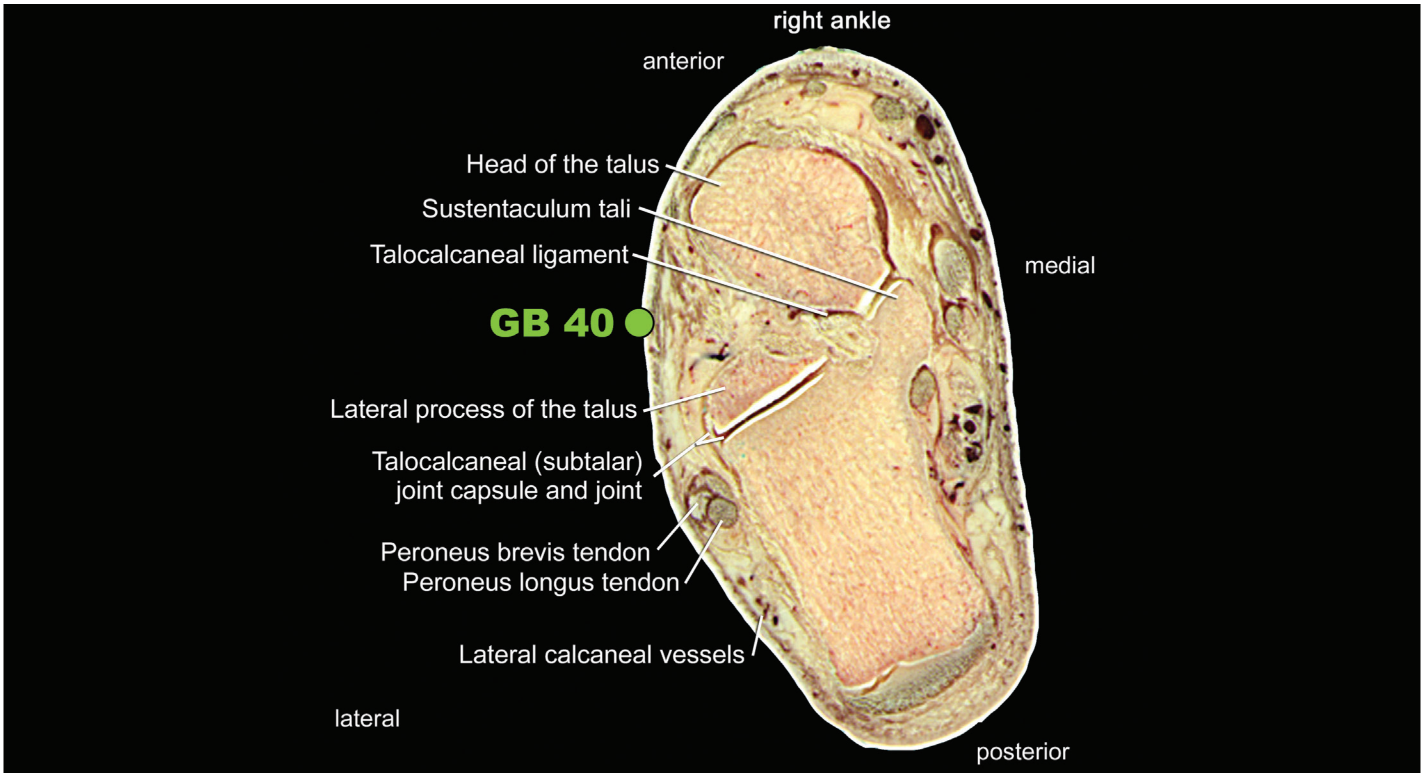

Figure 11-114. The interosseous talocalcaneal ligament, visible in this cross section, extends from the calcaneus to the talus, forming a transverse partition between the sulcus tali and the sulcus calcaneus. A functional link between the medial component of the inferior extensor retinaculum and the interosseous talocalcaneal ligament appears to exist, arguing for complex and extensive connective tissue continuity throughout the ankle joints.[25]

supply from the deep peroneal (fibular) nerve.

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation along the GB channel on the distal, lateral crus and dorsum of the foot that extends to the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer. Nonsurgical approaches that release the nerve and surrounding fascial restriction should be considered prior to surgery.[14]

Typically, nerve entrapment syndromes manifest as burning or "pins and needles" sensations, loss of coordination and proprioception in the limbs, symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial peroneal (fibular) nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated by resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem.

Distal entrapment of the deep peroneal (fibular) nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis, further distal on the limb.

Compression at GB 39 affects the superficial peroneal (fibular) nerve where it branches into the medial and intermediate dorsal cutaneous nerves. Anatomically, the superficial peroneal (fibular) nerve exits from deep fascia here. A fascial edge may impinge on the nerve, as may muscle that has herniated through fascial defects.[15] The superficial peroneal (fibular) nerve courses along a short fibrous tunnel located between the anterior intermuscular septum and the fascia of the lateral compartment. Patients with nerve entrapment at this location may be considered to exhibit a local compartment syndrome. Chronic ankle instability and sprain reinjures the nerve and predisposes individuals to develop a fibrotic, low compliant nature to this tunnel. Surgery may also cause problems, as it may shift the fascia following anterior compartment fasciotomy and place added stretch on the nerve. Iatrogenic injuries to the common peroneal (fibular) nerve and its branches stem from procedures that take a lateral or craniolateral approach to the knee, ankle, fibular, or soft tissue.

Ankle injuries, whether traumatic or iatrogenic, have the capacity to cause damage either directly or by accentuating the pressure from the inferior extensor retinaculum onto the intermediate dorsal cutaneous branch of the superficial peroneal (fibular) nerve as well as the lateral branch of the deep peroneal (fibular) nerve.[16]

A fracture of the fibular head may lacerate or compress one or more nerve branches and manifest as sensory and/or motor loss of varying degrees. Inflammation and edema after trauma may injure nerves as well.

Patients experiencing superficial peroneal (fibular) nerve entrapment at GB 39 complain of pain on the craniolateral calf and dorsum of the ankle and foot. Pain often lasts for years and recurs intermittently. About a third of patients report sensory changes along the distribution of the nerve, in the form of numbness or paresthesias. Activities such as running, squatting, jogging, or even walking worsen the problem. Focused palpation along the entire GB channel from GB 34 to GB 40 as well as the entire pelvic limb should provide insight into the source of myofascial dysfunction and the sites to needle or otherwise neuromodulate.

Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[17]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of sympathetic nervous system activity.[18,19]

Vessels

- **Lateral tarsal artery:** Branches off of the dorsalis pedis artery and anastomoses with branches of the arcuate, anterior lateral malleolar, and lateral plantar arteries. Also branches with the peroneal (fibular) artery.
- **Anterior lateral malleolar artery and vein:** Supply and drain the lateral ankle region.
- **Sinus tarsi artery:** Usually formed from anastomosing branches of the anterior tibial artery; i.e., the anterior lateral malleolar and proximal lateral tarsal artery.[20]
- **Veins of the sinus tarsi, with and without accompanying arteries:** Drain the tarsal sinus.

Clinical Relevance: Fractures of the proximal 5th metatarsal bone are some of the most common fractures that affect the foot; mechanisms involve falling from standing height or ankle twist with fixed forefoot.[21] Repetitive, cyclic loading can induce stress fractures of the 5th metatarsal. Inadequate circulation to this lateral portion of the foot contributes to incomplete or delayed fracture healing. Medical acupuncture, massage, and laser therapy support restoration of blood flow, resolution of pain, and bone healing.

The venous system of the sinus tarsi drains most of the blood from the talus as well as that from adjacent portions of the capsules surrounding the talocalcaneal and talocalcaneonavicular joints. Fibrotic changes affecting the walls of the veins and surrounding tissues may reduce venous outflow, increasing sinus pressure. Tissue swelling over the sinus at GB 40 may increase arterial inflow but also restrict venous outflow. Fibrosis may result from repeated ankle sprains and cause the aforementioned changes.

Indications and Potential Point Combinations

- **Tarsal sinus syndrome:** Lateral foot pain, perceived ankle instability, history of trauma involving inversion of the foot, typically found in patients in the 3rd or 4th decade of life, with worsened discomfort when pressure is applied over the lateral orifice of the tarsal sinus at GB 40: GB 40, GB 39, ST 39, BL 64, local trigger points as necessary.

Evidence-Based Applications

- A study evaluating the effects on cortical activation during stimulation of left LR 3 and left GB 40 revealed that, compared to the non-rotating stimulation method, rotating stimulation caused an **increase in activation in bilateral secondary somatosensory cortical areas, frontal areas, the right thalamus and the left side of the cerebellum.** Stimulation of sham points did not strengthen the effects of acupuncture on brain activation.[4]
- Acupuncture at GB 40 enhanced causal connectivity between the superior temporal gyrus and the anterior insula, in contrast to needling KI 3, which strengthened the connection between the **superior temporal gyrus and the postcentral gyrus.**[22]
- Electroacupuncture at GB 40 treated **migraine** significantly more effectively than did ST 25.[5]
- Electroacupuncture at GB 40, BL 63, LR 3, TH 5, ST 36, and LI 4 reduced requirements for sevoflurane and shortened recovery time after general anesthesia for patients undergoing **supratentorial craniotomy.**[23]

GB 41

Zu Lin Qi "Foot Governor of Tears", "Foot Overlooking Tears", "Foot Tears Control"

On the dorsum of the foot, in a depression distal to the junction of the bases of the 4th and 5th metatarsal bones, on the lateral aspect of the extensor digitorum longus tendon. Have the patient extend the little toe in order to identify the tendon.

Muscles and Tendons

- **4th dorsal interosseous muscle:** Abducts the digits and flexes the metatarsophalangeal joints.
- **Extensor digitorum longus tendon:** The extensor digitorum longus muscle extends the lateral four toes at the phalanges.
- **Extensor digitorum brevis tendon:** Extends digits II through IV at the metatarsophalangeal joint. Closely associated with the extensor hallucis brevis muscle; together, they form a fleshy mass on the lateral aspect of the dorsum of the foot, anterior to the lateral malleolus.

Clinical Relevance: Referred pain from extensor digitorum longus trigger points near GB 36 issue pain along the distal GB channel on the dorsum of the foot. Sustained myofascial dysfunction in the extensor digitorum along with the hallucis longus muscle can eventually deform the toes, leading to the "classic hammer toe" presentation. In this condition, the metatarsophalangeal joint of all four lesser toes extends while the proximal interphalangeal joint flexes. The distal interphalangeal joint also extends. These abnormal toe positions cause them to resemble "hammer heads". Wearing tight shoes precipitates the problem; as such, the remedy calls for switching to wide or box-toed shoes and pursuing a course of physical medicine to help undo the damage.

Hammer toes may cause or be worsened by trigger point pathology in the dorsal interosseous muscles. The interosseous muscles of the foot establish its architecture.[4] They provide for fine motor manipulation under normal circumstances.

Myofascial dysfunction in the superficial intrinsic muscles of the foot (including the extensor digitorum brevis muscle) leads to "sore feet". Trigger points in the extensor digitorum brevis near GB 40 send pain to the lateral dorsal surface, including GB 41 territory.

Thus, pain at GB 41 can manifest as a result of local pain from intrinsic muscles of the foot or referred pain from the long digital extensor muscle.

Nerves

- **Lateral plantar nerve, deep branches (S1, S2):** Supply the plantar and dorsal interossei, the lateral three lumbricals, and the adductor hallucis muscles.
- **Sural nerve:** Most commonly arises from the union of the medial sural cutaneous branch of the tibial nerve (L4-S3) and the sural communicating branch of the common peroneal

nerve (L4-S2). Innervates the lateral aspect of the foot. Courses posterior to the lateral malleolus, accompanying the small saphenous vein. Provides lateral calcaneal branches and terminates as the dorsal lateral cutaneous nerve of the foot. Certain afferent nerve neuromodulation techniques stimulate the sural nerve in order to treat voiding dysfunction, making use of the overlapping spinal cord of segments supplying both the pelvic limb and pelvic viscera.

- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot and all digits, except for the lateral side of the 5th pedal digit and the adjoining sides of the 1st and 2nd digits (which receives innervation from the deep peroneal nerve). Forms the dorsal digital nerves.
- **Deep peroneal (fibular) nerve (L5-S1):** Innervates the extensor digitorum longus and brevis, the extensor hallucis longus, and the peroneus (fibular) tertius muscles. Innervates the skin of between the first and second digits and metatarsi. Emits articular branches to the joints it crosses.[1]

Clinical Relevance: In accordance with Hilton's Law, the majority of nerves supplying joints also supply muscles that cross (and therefore move) the joint or the skin covering the articular insertion of these muscles. The articular branches may innervate the fibrous joint capsule, articular ligaments, or the synovial membrane. Some nerves carry sensation, while others supply nervi vasorum to the accompanying arteries. In distal portions of the limb, such as the hands or feet, the articular nerves arise as branches of cutaneous nerves supplying skin over the joint. This law is significant, because nerves serving acupuncture points also supply nearby joints, which helps explain why the treatment of joint pain often involves needling sites near the painful arthrodial structure.

From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[5] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-126) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Certain afferent nerve neuromodulation techniques stimulate the sural nerve in order to treat voiding dysfunction, making use of the overlapping spinal cord of segments supplying both the pelvic limb and pelvic viscera.[3]

The fascial sheath surrounding the caudal calf muscles will at times entrap the sural nerve as it emerges near BL 58. At the ankle, branches of the sural nerve can also experience compression. Heel pain accompanied by tingling, burning, or loss of sensation suggest neuropathic injury by compression, traction, or other causes.[6]

Figure 11-117. GB 41, "Foot Overlooking Tears", has notoriety for treating disorders of the eyes. Anatomically, GB 41 connects to the LR channel via the arcuate artery and the deep peroneal nerve, and in Chinese medicine, the LR channel relates to the eyes. From a vascular perspective, the indications for GB 41 associated with autonomic normalization may stem from the confluence of arterial pathways at this site, providing avenues for neuromodulation via the nervi vasorum, balancing sympathetic and parasympathetic function. Neuroanatomically, points associated with the peroneal nerve, (including the GB, LR, and BL lines) have been connected to visual function through certain functional brain imaging studies involving techniques such as fMRI.

along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[7] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-121B) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Lateral heel pain from lateral calcaneal neuritis (branches of the sural nerve) produces discomfort that radiates along the nerve, although the pain may be difficult to localize in some cases. This contrasts with calcaneal stress fracture that leads to pain over the entire calcaneus or peroneal (fibularis) tendon disorders that cause pain on the lateral calcaneus and peroneal tubercle.

Compression of the superficial peroneal (fibular) nerve by crural fascia causes "superficial peroneal (fibular) nerve syndrome". Near GB 39, this nerve emerges through the crural fascia and divides into two cutaneous branches, the medial dorsal and intermediate dorsal cutaneous nerves. The intermediate dorsal cutaneous nerve follows the GB channel to GB 40 and the toes while the medial dorsal cutaneous nerve accompanies the ST channel. The LR channel on the dorsum of the foot (from about LR 1-LR 3) receives sensation by the lateral branch of the deep peroneal (fibular) nerve but may include some fibers from the intermediate dorsal cutaneous nerve from superficial peroneal (fibular) origin.[8]

Fascial restriction can compress cutaneous branches as they cross the cranial ankle. If this occurs, sensation may be lessened to the craniolateral distal crus and ankle (GB 40), the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory supply from the deep peroneal (fibular) nerve.

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation along the GB channel on the distal, lateral crus and dorsum of the foot that extends to the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer. Nonsurgical approaches that release the nerve and surrounding fascial restriction should be considered prior to surgery.[9]

Typically, nerve entrapment syndromes manifest as burning or "pins and needles" sensations, loss of coordination and proprioception in the limbs, symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial peroneal (fibular) nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated by resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem.

Distal entrapment of the deep peroneal (fibular) nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis, further distal on the limb.

Compression at GB 39 affects the superficial peroneal (fibular) nerve where it branches into the medial and intermediate dorsal cutaneous nerves. Anatomically, the superficial peroneal (fibular) nerve exits from deep fascia here. A fascial edge may impinge on the nerve, as may muscle that has herniated through fascial defects.[10] The superficial peroneal (fibular) nerve courses along a short fibrous tunnel located between the anterior intermuscular septum and the fascia of the lateral compartment. Patients with nerve entrapment at this location may be considered to exhibit a local compartment syndrome. Chronic ankle instability and sprain reinjures the nerve and predisposes individuals to develop a fibrotic, low compliant nature to this tunnel. Surgery may also cause problems, as it may shift the fascia following anterior compartment fasciotomy and place added stretch on the nerve. Iatrogenic injuries to the common peroneal (fibular) nerve and its branches stem from procedures that take a lateral or craniolateral approach to the knee, ankle, fibular, or soft tissue.

Ankle injuries, whether traumatic or iatrogenic, have the capacity to cause damage either directly or by accentuating the pressure from the inferior extensor retinaculum onto the intermediate dorsal cutaneous branch of the superficial peroneal (fibular) nerve as well as the lateral branch of the deep peroneal (fibular) nerve.[11]

Patients experiencing superficial peroneal (fibular) nerve entrapment complain of pain on the craniolateral calf and dorsum of the ankle and foot. Pain often lasts for years and recurs intermittently. About a third of patients report sensory changes along the distribution of the nerve, in the form of numbness or paresthesias. Activities such as running, squatting, jogging, or even walking worsen the problem. Focused palpation along the entire GB channel from GB 34 to GB 40 as well as the entire pelvic limb should provide insight into the source of myofascial dysfunction and the sites to needle or otherwise neuromodulate.

Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[12]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of sympathetic nervous system activity.[13,14]

Vessels

- **Dorsal venous arch of the foot:** Arises from the dorsal metatarsal veins.
- **4th dorsal metatarsal artery:** Arises from the arcuate artery, supplies the 4th metatarsal region.
- **4th dorsal metatarsal vein:** Arises from dorsal digital vein; drains into the dorsal venous arch.
- **Arcuate artery:** The 2nd, 3rd, and 4th metatarsal arteries arise from the arcuate artery, and divide into two dorsal digital arteries that course along the sides of adjoining toes. The metatarsal arteries are, in turn, connected to the plantar arch and plantar metatarsal arteries via the perforating arteries. The arcuate artery is not always present, but instead a dorsal arterial network consisting of the lateral tarsal artery and dorsal metatarsal arteries and proximal perforating arteries may[15] contribute to the blood supply of metatarsal arteries II through IV.

Clinical Relevance: The nervi vasorum associated with the arcuate artery may be responsible for autonomic neuromodulation derived from needling this site.

Dorsal interosseous muscles receive arterial blood via segmental branches off of their respective dorsal metatarsal arteries. The dorsal metatarsal arteries originate from the dorsalis pedis artery and connect with the vascular network on the plantar foot through a proximal and dorsal perforating artery. Microangiopathy or other vascular failures in patients such as diabetic individuals can compromise circulation and limit collateral vessel support, should one channel become obstructed or damaged.[16]

Indications and Potential Point Combinations

- **Cramping or pain of the lateral dorsum of the foot:** GB 41, GB 42, GB 36, ST 43, ST 44, BL 60.
- **Ocular disorders and visual disturbances:** GB 41, LR 3, GB 1, TH 23, BL 2, GB 14, BL 10.Note that despite its illustrative name, GB 41 does not ordinarily appear in treatments for eye conditions. The local points likely have a far greater impact. However, as critical thinkers about acupuncture argue, we must measure the traditional indications of acupuncture points as presented in ancient literature against what actually occurs in the clinic, and modify recommendation as necessary.[2,3]

GB 42

Di Wu Hui "Earth Five Meetings", "Earth Fivefold Convergence", "Pinched Ravine"

On the dorsum of the foot, in a depression proximal to the heads of the 4th and 5th metatarsal bones, on the medial side of the of the extensor digitorum longus tendon, approximately 0.5 cun distal to GB 41.

Muscles and Tendons

- **4th dorsal interosseous muscle:** Abducts the digits and flexes the metatarsophalangeal joints.
- **Extensor digitorum brevis tendon:** Extends digits II through IV at the metatarsophalangeal joint. Closely associated with the extensor hallucis brevis muscle; together, they form a fleshy mass on the lateral aspect of the dorsum of the foot, anterior to the lateral malleolus.
- **Extensor digitorum longus tendon:** The extensor digitorum longus muscle extends the lateral four toes at the phalanges.

Clinical Relevance: Proper function of the long digital extensors allows one to operate the toes normally during ambulation, clearing the ground with the foot during the swing phase. The extensor digitorum longus, thus critical for normal biomechanics of the foot, extends the proximal phalanx of the four lateral toes and assists in dorsiflexion and eversion of the foot.

Referred pain from extensor digitorum longus trigger points near GB 36 issue pain along the distal GB channel on the dorsum of the foot toward GB 42. Sustained myofascial dysfunction in the extensor digitorum along with the hallucis longus muscle can eventually deform the toes, leading to the "classic hammer toe" presentation. In this condition, the metatarsophalangeal joint of all four lesser toes extends while the proximal interphalangeal joint flexes. The distal interphalangeal joint also extends. These abnormal toe positions cause them to resemble "hammer heads". Wearing tight shoes precipitates the problem; as such, the remedy calls for switching to wide or box-toed shoes and pursuing a course of physical medicine to help undo the damage.

Hammer toes may cause or be worsened by trigger point pathology in the dorsal interosseous muscles. The interosseous muscles of the foot establish its architecture.[2] They provide for fine motor manipulation under normal circumstances.

Myofascial dysfunction in the superficial intrinsic muscles of the foot (including the extensor digitorum brevis muscle) leads to "sore feet". Trigger points in the extensor digitorum brevis near GB 40 send pain to the lateral dorsal surface, including GB 41 and possibly even GB 42 territory. Thus, pain at GB 42 may manifest as a result of local pain from intrinsic muscles of the foot or referred pain from the long digital extensor muscle.

Deep intrinsic muscles of the foot such as the interosseous muscles support its strength and architecture.[3] They provide for fine motor manipulation under normal circumstances.

Nerves

- **Lateral plantar nerve, deep branches (S1, S2):** Supply the plantar and dorsal interossei, the lateral three lumbricals, and the adductor hallucis muscles.
- **Sural nerve:** Most commonly arises from the union of the medial sural cutaneous branch of the tibial nerve (L4-S3) and the sural communicating branch of the common peroneal nerve (L4-S2). Innervates the lateral aspect of the foot. Courses caudal to the lateral malleolus, accompanying the small saphenous vein. Provides lateral calcaneal branches and terminates as the dorsal lateral cutaneous nerve of the foot. Certain afferent nerve neuromodulation techniques stimulate the sural nerve in order to treat voiding dysfunction, making use of the overlapping spinal cord of segments supplying both the pelvic limb and pelvic viscera.[1]
- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot and all digits, except for the lateral side of the 5th pedal digit and the adjoining sides of the 1st and 2nd digits (which receives innervation from the deep peroneal (fibular) nerve). Becomes the dorsal digital nerves.
- **Deep peroneal (fibular) nerve (L5-S1):** Innervates the extensor digitorum longus and brevis, the extensor hallucis longus, and the peroneus (fibular) tertius muscles. Innervates the skin of between the first and second digits and metatarsi. Emits articular branches to the joints it crosses.

Clinical Relevance: The lateral plantar nerve may suffer entrapments at several locations from where it branches off of the tibial nerve to its myriad destinations.

Ligamentous laxity or myofascial dysfunction in the foot may lead to nerve irritation. If this occurs between the 4th and 5th metatarsal bones, acupuncture stimulation of GB 42 may aid in its resolution.

In accordance with Hilton's Law, the majority of nerves supplying

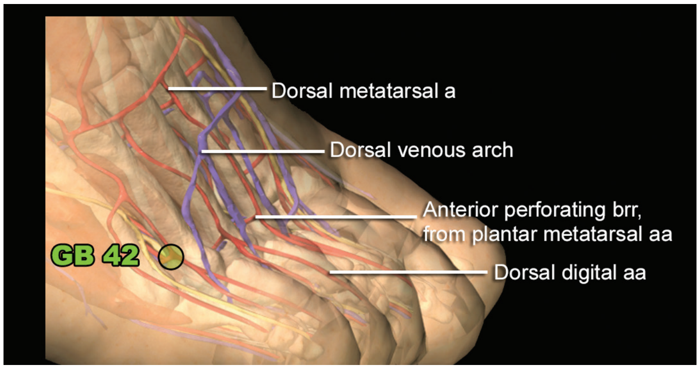

Figure 11-118. The illustrative name for GB 42, indicating a convergence of "five" components connotes several possibilities. Five arteries feed this site, as suggested by the names "Earth Five Meetings" and "Earth Fivefold Convergence", with "Earth" in Chinese medicine representing the nourishing nature of blood. The five arteries converging here include a dorsal and ventral metatarsal artery, an adjoining anterior perforating branch connecting the two metatarsal arteries, and the two dorsal digital arteries that bifurcate distal to this point. Alternatively, the number five might allude to the five toes touching the ground (Earth). The name "Pinched Ravine" for GB 42 speaks to the narrowness of the intertarsal groove through which the fluid-bearing channels of the metatarsal artery and vein ferry nutrients.

joints also supply muscles that cross (and therefore move) the joint or the skin covering the articular insertion of these muscles. The articular branches may innervate the fibrous joint capsule, articular ligaments, or the synovial membrane. Some nerves carry sensation, while others supply nervi vasorum to the accompanying arteries. In distal portions of the limb, such as the hands or feet, the articular nerves arise as branches of cutaneous nerves supplying skin over the joint. This law is significant, because nerves serving acupuncture points also supply nearby joints, which helps explain why the treatment of joint pain often involves needling sites near the painful arthrodial structure.

Distal points such as GB 42 exhibit a relatively greater proportion of sensory and sympathetic fibers than do more proximal sites. As such, they offer, perhaps, greater opportunities to neuromodulate the autonomic flavor of the associated nerve's actions than do their proximal counterparts.

From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[4] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-126) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Certain afferent nerve neuromodulation techniques stimulate the sural nerve in order to treat voiding dysfunction, making use of the overlapping spinal cord of segments supplying both the pelvic limb and pelvic viscera.[4]

The fascial sheath surrounding the caudal calf muscles will at times entrap the sural nerve as it emerges near BL 58. At the ankle, branches of the sural nerve can also experience compression. Heel pain accompanied by tingling, burning, or loss of sensation suggest neuropathic injury by compression, traction, or other causes.[5]

Lateral heel pain from lateral calcaneal neuritis (branches of the sural nerve) produces discomfort that radiates along the nerve, although the pain may be difficult to localize in some cases. This contrasts with calcaneal stress fracture that leads to pain over the entire calcaneus or peroneal (fibularis) tendon disorders that cause pain on the lateral calcaneus and peroneal tubercle.

Compression of the superficial peroneal (fibular) nerve by crural fascia causes "superficial peroneal (fibular) nerve syndrome". Near GB 39, this nerve emerges through the crural fascia and divides into two cutaneous branches, the medial dorsal and intermediate dorsal cutaneous nerves. The intermediate dorsal cutaneous nerve follows the GB channel to GB 40 and the toes while the medial dorsal cutaneous nerve accompanies the ST channel. The LR channel on the dorsum of the foot (from about LR 1-LR 3) receives sensation by the lateral branch of the deep peroneal (fibular) nerve but may include some fibers from the intermediate dorsal cutaneous nerve from superficial peroneal (fibular) origin.[6]

Fascial restriction can compress cutaneous branches as they cross the cranial ankle. If this occurs, sensation may be lessened to the craniolateral distal crus and ankle (GB 40), the dorsum of the foot, and the dorsal skin of the great, second, third, and medial fourth toes. It spares a wedge of skin between the great and second toe, as this site section receives sensory supply from the deep peroneal (fibular) nerve.

Patients with superficial peroneal (fibular) nerve syndrome report pain or impaired sensation along the GB channel on the distal, lateral crus and dorsum of the foot that extends to the ST and LR channels. Exacerbating athletic activities include running, dancing, bodybuilding, tennis, horseback riding (specifically in jockeys), and soccer. Nonsurgical approaches that release the nerve and surrounding fascial restriction should be considered prior to surgery.[7]

Typically, nerve entrapment syndromes manifest as burning or "pins and needles" sensations, loss of coordination and proprioception in the limbs, symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or

Figure 11-120. The small and tightly packaged intrinsic muscles of the foot reveal its intricate architecture that affords nuanced control of balance and movement. This cross section exposes the number of vessels under the skin, each ready to ferry autonomic information to and fro through their nervi vasorum. Both local and whole body autonomic neuromodulation can result from acupuncture applied to distal points on the hands and feet.

gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial peroneal (fibular) nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated by resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem.

Distal entrapment of the deep peroneal (fibular) nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis, further distal on the limb.

Compression at GB 39 affects the superficial peroneal (fibular) nerve where it branches into the medial and intermediate dorsal cutaneous nerves; the latter impacts GB 42. Anatomically, the superficial peroneal (fibular) nerve exits from deep fascia here. A fascial edge may impinge on the nerve, as may muscle that has herniated through fascial defects.[8] The superficial peroneal (fibular) nerve courses along a short fibrous tunnel located between the anterior intermuscular septum and the fascia of the lateral compartment. Patients with nerve entrapment at this location may be considered to exhibit a local compartment syndrome. Chronic ankle instability and sprain reinjures the nerve and predisposes individuals to develop a fibrotic, low compliant nature to this tunnel. Surgery may also cause problems, as it may shift the fascia following anterior compartment fasciotomy and place added stretch on the nerve. Iatrogenic injuries to the common peroneal (fibular) nerve and its branches stem from procedures that take a lateral or craniolateral approach to the knee, ankle, fibular, or soft tissue.

Ankle injuries, whether traumatic or iatrogenic, have the capacity to cause damage either directly or by accentuating the pressure from the inferior extensor retinaculum onto the intermediate dorsal cutaneous branch of the superficial peroneal (fibular) nerve as well as the lateral branch of the deep peroneal (fibular) nerve.[9]

Patients experiencing superficial peroneal (fibular) nerve entrapment complain of pain on the craniolateral calf and dorsum of the ankle and foot. Pain often lasts for years and recurs intermittently. About a third of patients report sensory changes along the distribution of the nerve, in the form of numbness or paresthesias. Activities such as running, squatting, jogging, or even walking worsen the problem. Focused palpation along the entire GB channel from GB 34 to GB 40 as well as the entire pelvic limb should provide insight into the source of myofascial dysfunction and the sites to needle or otherwise neuromodulate.

Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[10]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of sympathetic nervous system activity.[11,12]

Vessels

- **4th dorsal metatarsal artery:** Arises from the arcuate artery, supplies the 4th metatarsal region.
- **4th dorsal metatarsal vein:** Arises from dorsal digital vein; drains into the dorsal venous arch.

Clinical Relevance: Dorsal interosseous muscles receive arterial blood via segmental branches off of their respective dorsal metatarsal arteries. The dorsal metatarsal arteries originate from the dorsalis pedis artery and connect with the vascular network on the plantar foot through a proximal and dorsal perforating artery. Microangiopathy or other vascular failures in patients such as diabetic individuals can compromise circulation and limit collateral vessel support, should one channel become obstructed or damaged.[13]

Indications and Potential Point Combinations

- **Dorsal foot pain, night cramps in the long extensors of the toes, and "growing pains" in children due to myofascial trigger points:** GB 42, GB 35, GB 36, other pertinent trigger points involved in the patient's individual pain problem.
- **Sore feet with pain on walking:** GB 42, GB 40, palpate for trigger points in the superficial intrinsic foot muscles, including the extensor digitorum brevis, the extensor hallucis brevis, the abductor hallucis, the abductor digiti minimi, and the flexor digitorum brevis.

GB 43

Xia Xi "Clamped Stream", "Pinched Ravine", "Tight Torrent"

Distal to the 4th and 5th metatarsophalangeal joints, 0.5 cun proximal to the web margin between the 4th and 5th toes.

Tendons

- **Tendons of the extensor digitorum longus and brevis muscles for the 4th and 5th toes:** Extend the toes.

Clinical Relevance: Proper function of the long digital extensors allows one to operate the toes normally during ambulation, clearing the ground with the foot during the swing phase. The extensor digitorum longus, thus critical for normal biomechanics of the foot, extends the proximal phalanx of the four lateral toes and assists in dorsiflexion and eversion of the foot.

Myofascial dysfunction in the superficial intrinsic muscles of the foot (including the extensor digitorum brevis muscle) leads to "sore feet". Trigger points in the extensor digitorum brevis near GB 40 send pain to the lateral dorsal surface, including landscape as far as GB 43. Thus, pain at GB 43 may manifest as a result of local pain from intrinsic muscles of the foot or referred pain from the long digital extensor muscle. Deep intrinsic muscles of the foot such as the interosseous muscles support its strength and architecture.[3] They provide for fine motor manipulation under normal circumstances.

Referred pain from extensor digitorum longus trigger points near GB 36 issues pain along the distal GB channel on the dorsum of the foot toward GB 43. Sustained myofascial dysfunction in the extensor digitorum along with the hallucis longus muscle can eventually deform the toes, leading to the "classic hammer toe" presentation. In this condition, the metatarsophalangeal joint of all four lesser toes extends while the proximal interphalangeal joint flexes. The distal interphalangeal joint also extends. These abnormal toe positions cause them to resemble "hammer heads". Wearing tight shoes precipitates the problem; as such, the remedy calls for switching to wide or box-toed shoes and pursuing a course of physical medicine to help undo the damage.

Hammer toes may cause or be worsened by trigger point pathology in the dorsal interosseous muscles. The interosseous muscles of the foot establish its architecture.[4] They provide for fine motor manipulation under normal circumstances.

Nerves

- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot and all digits, except for the lateral side of the 5th pedal digit and the adjoining sides of the 1st and 2nd digits (which receives innervation from the deep peroneal (fibular) nerve). Forms the dorsal digital nerves.
- **Deep peroneal (fibular) nerve (L5-S1):** Innervates the extensor digitorum longus and brevis, the extensor hallucis longus, and the peroneus (fibular) tertius muscles. Innervates the skin of between the first and second digits and metatarsi. Emits articular branches to the joints it crosses.

Clinical Relevance: Nerve stimulation via acupuncture and related techniques at GB 43 and its partner points near neighboring web spaces may aid in the restoration of sensation and motor control to the distal pelvic limb. Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[5]

Distal points such as GB 43 exhibit a relatively greater proportion of sensory and sympathetic fibers than do more proximal sites. As such, they offer, perhaps, greater opportunities to neuromodulate autonomic aspects of the associated nerve's actions than do their proximal counterparts.

Vessels

- **4th dorsal metatarsal artery:** Arises from the 4th metatarsal artery, where it divides into two dorsal digital arteries, going to the 4th and 5th toes.

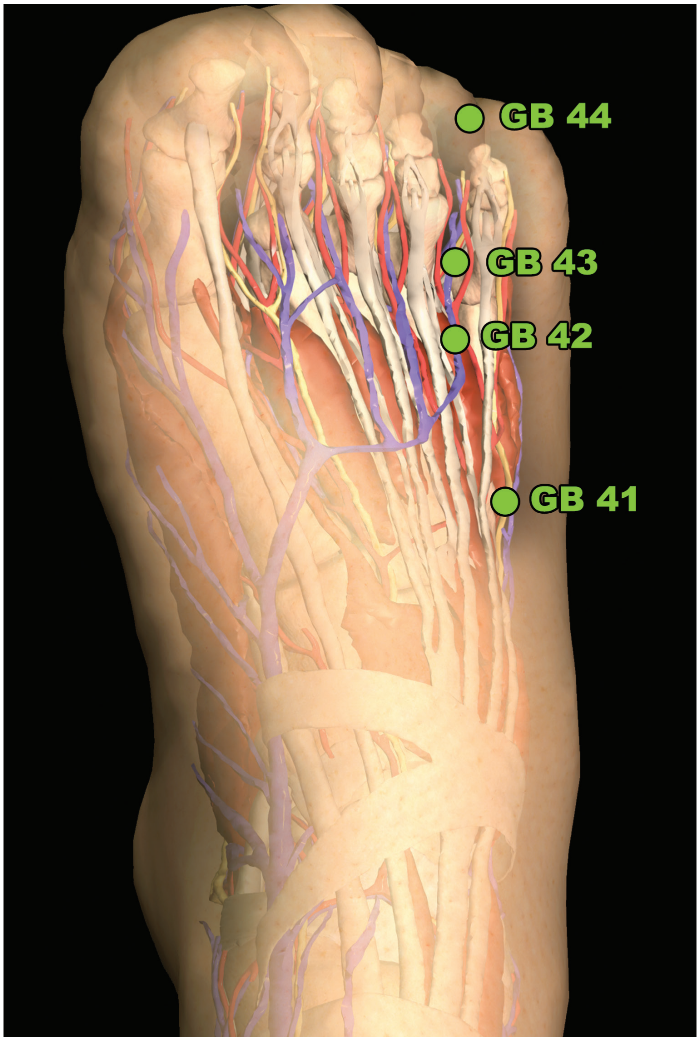

Figure 11-121. Points within the webs between the toes such as GB 43 access digital nerve bifurcations. Stimulation here promotes recovery of nerve function in cases of pelvic limb paresis or paralysis. Web space points on the foot called "Bafeng", or "Eight Winds", for their elimination of metaphorical "wind", i.e., nerve injury or pain. Corresponding points on the hand, "Baxie", go by the name "Eight Pathogens" or "Eight Evils", referring to the invasion of metaphorical pernicious influences into the hand through the web spaces.

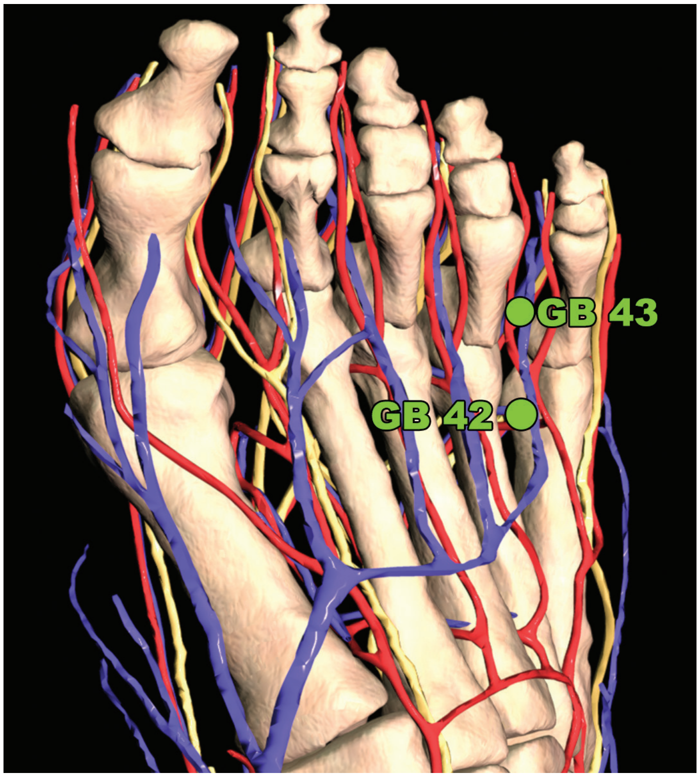

Figure 11-122. As the vessels feeding the GB channel narrow, the relative proportion of sympathetic fiber supply increases, causing stimulation of these sties to deliver progressively greater impacts on systemic autonomic function and local hemodynamics. The descriptive titles for GB 43 of "Tight Torrent", "Pinched Ravine", and "Clamped Stream" pertain to the diminishing diameter of the arterial architecture at this distal site.

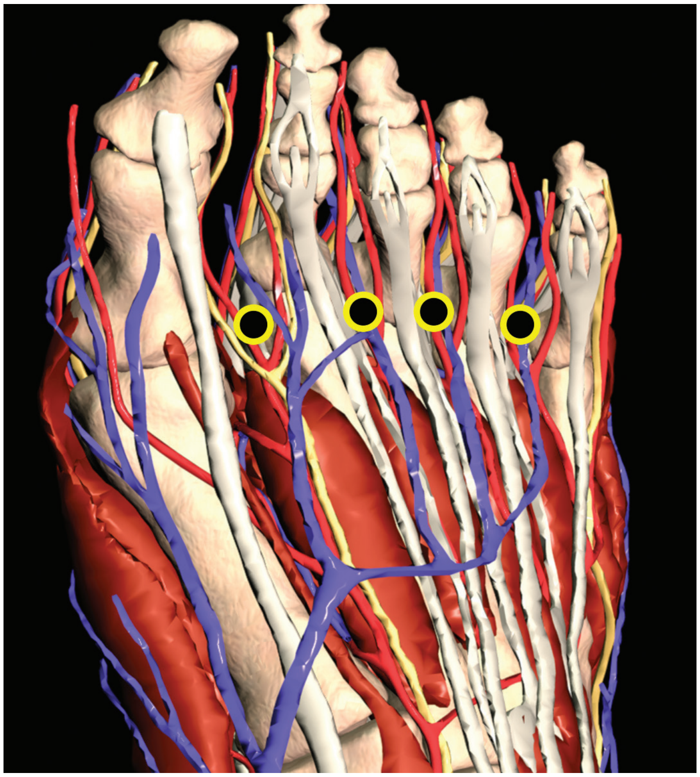

Figure 11-123. The "Bafeng" or "Eight Wind" points comprise four locations on each foot, located at the web spaces between the toes. These areas exhibit high neurovascular traffic and thus provide excellent options for acupuncture intervention in patients with problems of impaired neurologic function and circulation. Three of the Bafeng points overlap with standard acupuncture points, including LR 2 between the big and 2nd toe, ST 44 between the 2nd and 3rd toes, and GB 43, between the 4th and 5th toes, leaving the spot between the 3rd and 4th toes without an alternate designation. However, given its anatomical similarity to the other points, clinical indications for pain, circulatory insufficiency, and neurologic impairment still apply.

- **4th dorsal metatarsal vein:** Arises from dorsal digital vein; drains into the dorsal venous arch.

Clinical Relevance: Dorsal interosseous muscles receive arterial blood via segmental branches off of their respective dorsal metatarsal arteries. The dorsal metatarsal arteries originate from the dorsalis pedis artery and connect with the vascular network on the plantar foot through a proximal and dorsal perforating artery. Microangiopathy or other vascular failures in patients such as diabetic individuals can compromise circulation and limit collateral vessel support, should one channel become obstructed or damaged.[6]

Distal osteotomies performed to treat claw toe deformities and metatarsalgia may damage the intraosseous arterial network of the metatarsal head. The nutrient arteries that feed the head are terminal end arteries, making this section more prone to osteonecrosis following iatrogenic or traumatic injury than the metatarsal diaphysis.[7] If injury does occur to this vascular network, points such as GB 43 may suggest sites for acupuncture, massage, and laser therapy that may aid in restoring circulation by improving tissue perfusion, limiting inflammation, and stimulating regrowth.

Indications and Potential Point Combinations

- **Cold feet and legs:** GB 43 and the remaining three "Bafeng" points on each foot (See Figure 3). LR2, SP6.
- **Swollen feet:** GB 43 and the other Bafeng, SP 5, SP 6, ST 36.
- **Tension or pain in the toes:** GB 43 and pertinent trigger points evoking referred pain in the digits; consider Bafeng. GB 35, GB 36, ST 36 for referred pain by the extensor digitorum and anterior tibial muscles.
- **Lumbosacral pain:** GB 43, BL 40, local back points tender to palpation. Examine BL 23, BL 25, GV 3, GV 4, BL 32.
- **Impaired brain processing of sound and language:** GB 43, GB and TH points around the ear that exhibit tenderness to palpation.
- **Inflammation in the eyes:** GB 43, GB 2, GB 1, TH 23, BL 2, GV 20.

Evidence-Based Applications

- Laser stimulation of GB 43 showed significant brain activation in the ipsilateral thalamus, nucleus subthalamicus, nucleus ruber, midbrain, and Brodmann Areas (BA) 40 and 22. On the right side of the brain, BA 40 and 22 help **process sound and**

language, which are consistent with some of the classical applications of this point.[1]

- Acupuncture at the spinal nerve points from L4-S1, along with GB 43, GB 36, BL 40, and an injection of Gegensu Zhusheye (Puerarin Injectio) improved the signs and symptoms related to **lumbar intervertebral disk disease,** the activities of daily living, and analgesic states as compared to injection alone. The mechanism putatively involved at least in part, changes in cytokine and hemodynamic states.[2]
- Laser acupuncture (50 mW, continuous radiation for 90 seconds, totaling 4.5 J and 1250 W per cm2) applied to GB 43, GB 20, LI 4, LR 3, ST 6, SI 19, NT3, and EX-HN 3 reduced chronic pain associated with **temporomandibular dysfunction.**[8]

GB 44

Zu Qiao Yin "Yin Portals of the Foot", "Foot Orifice Yin"

On the lateral side of the base of the nail of the 4th toe, the width of a Chinese leek leaf from the corner of the nail.

Nerves

- **Superficial peroneal (fibular) nerve (L5-S2):** Innervates the peroneus longus and brevis muscles. Supplies the skin on the distal third of the leg and dorsum of the foot and all digits, except for the lateral side of the 5th pedal digit and the adjoining sides of the 1st and 2nd digits (which receive innervation from the deep peroneal nerve). Forms the dorsal digital nerves.

Clinical Relevance: The abundant supply of sensory nerve fibers at the ting points of the digits provide ample opportunities to neuromodulate and improve nerve function in cases of sensory or motor compromise.

Vessels

- **4th dorsal digital artery:** Arises from the 4th metatarsal artery.
- **4th dorsal digital vein:** Communicates with the plantar digital veins.

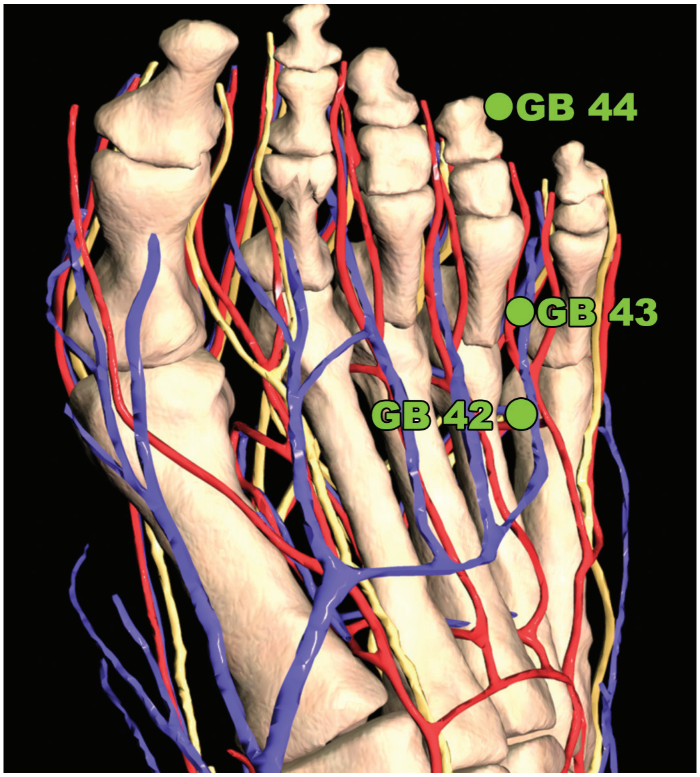

Figure 11-124. "Foot Orifice Yin" for GB 44 suggests the ancient idea of the "five orifices" connoting the sensory organs on the head; i.e., the eyes, mouth, nose, tongue, and ears. In Chinese medicine, each of these facial features relates to internal organs, specifically the liver, spleen, lungs, heart, and kidney, respectively. As such, stimulating GB 44 was viewed as a means to impact physiologic function not only on the head but also internally. The neuromodulatory impact of GB 44 relates to its heavy investment of sympathetic fibers at these distal arterioles and capillaries. Note: Only the larger distal vessels appear in this image.

Clinical Relevance: The characteristics of "ting" points (i.e., those most distal on the channel) that tend to produce strong hemodynamic shifts result from the abundant nervi vasorum associated with the ever-narrowing arterioles. Despite their small size, these "nerves of the vessels" are capable of inducing profound autonomic shifts.

Indications and Potential Point Combinations

- **Fever:** GB 44, LI 4, LI 11, GV 14, GV 20, ST 36.
- **Headaches around the eyes:** GB 44, GB 20, BL 9, BL 2, Tai Yang, relevant trigger points, LR 3.
- **Dizziness, vertigo:** GB 44, Tai Yang, GV 20, GB 20, ST 36.
- **Foot pain or swelling on the dorsum:** Palpate to define trigger points in the crus potentially responsible for referred pain. Add local points, GB 44, laser therapy, and massage.
- **Deafness, tinnitus:** GB 44, GB 20, temporalis trigger points, BL 10.
- **Eye pain:** GB 44, GB 1, TH 23, BL 2, LI 4, GV 14, ST 36.

Evidence-Based Applications

- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain:** KI 3, KI 10, SI 3, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, GB 44, and SI 18.[1]
- Acupuncture at GB 44, BL 67, ST 45, SP 1, SP 6, KI 1 (as located on the midpoint of the third toe rather than the bottom of the foot), KI 7, BL 58, ST 40, ST 36, TH 1, HT 9, SI 1, LR 1, LU 11, LI 1, LI 4, LU 9, CV 17, and moxa at GV 14 promoted rapid resolution of **staphylococcal skin wounds** otherwise unresponsive to 50 days of treatment with antibiotics and deemed life-threatening in a 13-month-old child with Noonan's syndrome.[2]

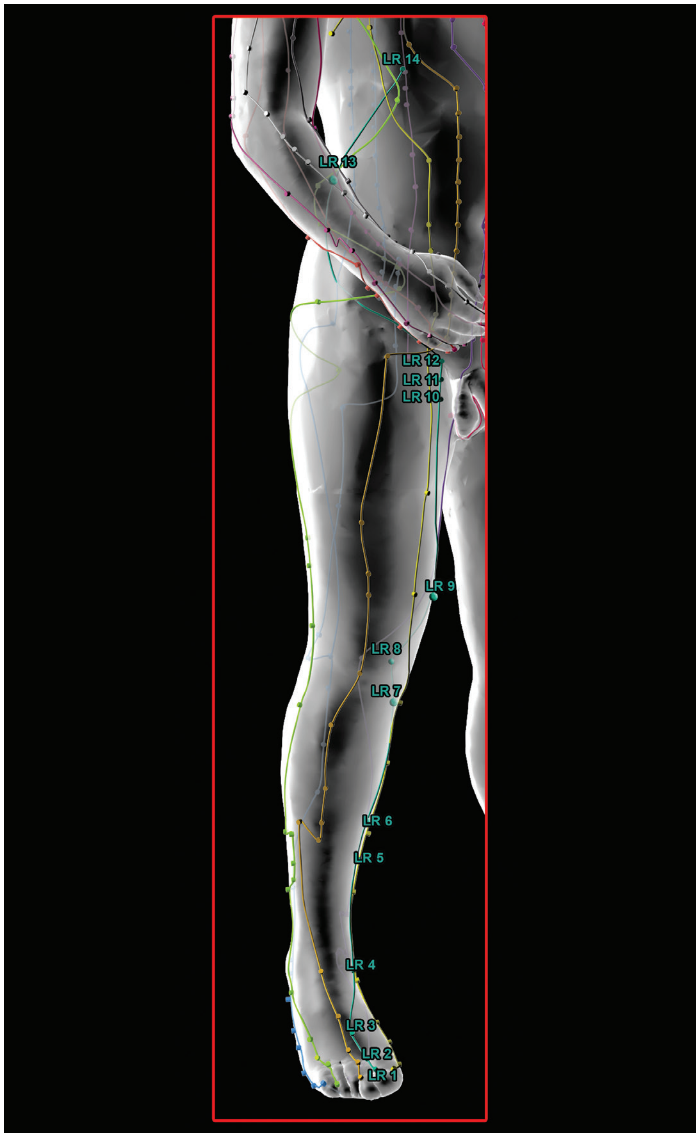
Channel 12:: The Liver (LR)

The LR channel starts its trek at LR 1 on the lateral aspect of the big toe. It ascends the medial surface of the leg and thigh to reach the femoral vein at the groin. From here, the Liver channel deviates backward then forward, ending over the liver at LR 14. The Liver channel pathway follows its neighboring channel, the Spleen line, in a roughly parallel voyage from the big toe to the femoral triangle. They crisscross over great saphenous vein and its tributaries, and crisscross as they migrate toward the trunk.



The LR channel starts its trek toward the liver organ on the big toe. It ascends the medial pelvic limb to reach the femoral vein in the groin. From there, the LR line reaches back to the 11th rib, then forward toward the liver.

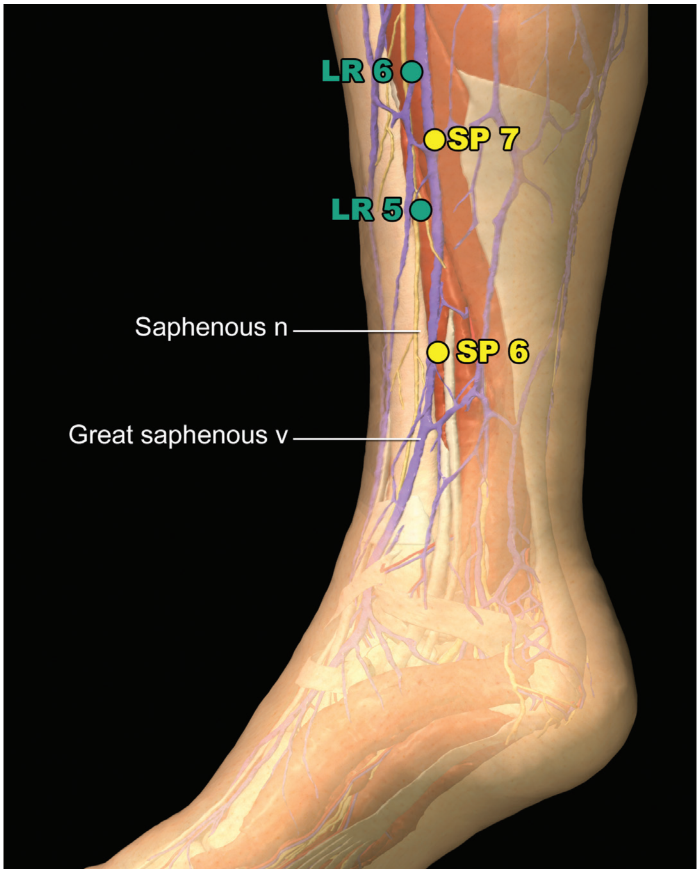
LR 1

The first few points of the LR line occupy a unique strip of territory on the dorsum of the foot supplied by the deep peroneal (fibular) nerve. This sets the LR line apart from other channels on the foot. The SP, ST, and GB lines share superficial peroneal (fibular) nerve supply while the BL line derives its sensory supply from the lateral dorsal cutaneous nerve.



LR 6
SP 7
LR 5
Saphenous n
SP 6

The LR line ends its journey over the liver organ at LR 14, the Front Mu point for the Liver. Its next-door neighbor, GB 24, the Front Mu point for Gallbladder, lives in the next intercostal space over the gallbladder.

LR 1

Da Dun "Big Mound", "Big Thick", "Large Pile"

On the lateral side of the base of the nail of the great toe, the width of a Chinese leek leaf from the corner of the nail. Or, midway between the proximal lateral corner of the nail and the interphalangeal joint.

Nerves

- **Deep peroneal (fibular) nerve:** Supplies the skin on the adjoining sides of the 1st and 2nd toes.
- **Proper plantar digital branches of the medial plantar nerve:** Supply the dorsal surfaces of the distal tips of the toes (in the nail bed regions).

Clinical Relevance: The abundance of somatic and autonomic nerve fibers at ting (i.e., most distal) points on the digits offers ample opportunities for somatic and sympathetic neuromodulation. However, these points are rarely needled due to their heightened sensitivity. Clinically, the deep peroneal (fibular) nerve may provide a stronger effect on autonomic regulation than its superficial counterpart. Consider, for example, the impact of ST 36 on the autonomic nervous system, derived largely from its deep peroneal (fibular) connections. LR 1, LR 2, and LR 3 continue in this tradition with some differences. ST 36 surrounds itself with a rich supply of muscle afferents whereas distal LR points live in tissue replete with nervi vasorum. Different afferent fibers activated during acupuncture and related techniques cause different neuromodulatory outcomes.

Vessels

- **Proper plantar digital artery:** Supplies the dorsum of the distal phalangeal segment and nail bed. Arises from the metatarsal artery, which in turn arose from the plantar arterial arch.
- **Dorsal digital artery:** Supplies the great toe. Arises from the 1st dorsal metatarsal artery.
- **Dorsal venous arch of the foot:** Formed by the union of the dorsal metatarsal veins. The dorsal venous arch communicates with the plantar venous arch. Both drain into the great saphenous vein on the medial aspect and the small saphenous vein on the lateral aspect of the distal pelvic limb.

Clinical Relevance: Vessels of the foot and hand afford opportunities for local and systemic autonomic neuromodulation and hemodynamic regulation. Hemodynamic changes result from ting point needling and improve local circulation to the acral extremity. This may promote nerve health in cases of peripheral neuropathy. Nervi vasorum connect to higher centers and influence systemic sympathetic control as well.

Indications and Potential Point Combinations

- **Gynecologic issues:** Metrorrhagia, menorrhagia, uterine prolapse, vaginitis: LR 1, SP 6, SP 10, CV 4.
- **Urinary problems:** urethritis, urinary incontinence, enuresis, voiding dysfunction: LR 1, SP 6, KI 3, KI 10, CV 3.
- **Seizures:** LR 1, LR 2, GB 34, ST 36, GV 20, GB 20, HT 7.

LR 2

Xing Jian "Moving Between"

On the dorsum of the foot, distal to the 1st and 2nd metatarsophalangeal joints, 0.5 cun proximal to the web margin.

Muscles

- **1st dorsal interosseous muscle:** Abducts the digits and flexes the metatarsophalangeal joints.

Clinical Relevance: Deep intrinsic muscles of the foot such as the interosseous muscles support its strength and architecture.[6] They provide for fine motor manipulation under normal circumstances.

Nerves

- **Deep peroneal nerve (L4-S1):** Supplies the skin on the adjoining sides of the 1st and 2nd toes. Also supplies the extensor digitorum brevis muscle and other muscles in the anterior compartment.
- **Proper plantar digital branches of the medial plantar nerve:** Supply the dorsal surfaces of the distal tips of the toes (in the nail bed regions).
- **Lateral plantar nerve (S2-S3):** Supplies all dorsal interosseous muscles of the foot. A branch of the tibial nerve.

Clinical Relevance: The abundance of somatic and autonomic nerve fibers points on the digits offers ample opportunities for somatic and sympathetic neuromodulation. Clinically, the deep peroneal (fibular) nerve may provide a stronger effect on autonomic regulation than its superficial counterpart. Consider, for example, the impact of ST 36 on the autonomic nervous system, derived largely from its deep peroneal (fibular) connections. LR 1, LR 2, and LR 3 continue in this tradition with some differences. ST 36 surrounds itself with a rich supply of muscle afferents whereas distal LR points live in tissue replete with nervi vasorum. Different afferent fibers activated during acupuncture and related techniques cause different neuromodulatory outcomes.

Like the ulnar nerve in the hand that supplies the dorsal interosseous muscles, the lateral plantar nerve supplies all of the foot's dorsal interosseous muscles. Resemblances between acupuncture points and neural control of the thoracic and pelvic limbs include more than merely anatomical similarities.

Fast-adapting afferents at LR 2 and LR 3, among other locations on the dorsal foot, demonstrate a significant coupling response with muscles of the thoracic limb. Through these connections, cutaneous afferents from the foot have the capacity to influence kinesthesia, reflexes, and tactile perception in the thoracic limb.[7] These findings suggest that cutaneous input from the foot may play an important role in coordinating interlimb activity. Clinical implications include acupuncture and related techniques for stroke recovery, spinal cord injury, degenerative neurologic conditions, and peripheral nerve injury. Clearly, LR 2 and LR 3 should be considered for supporting recovery of thoracic limb strength.

Vessels

- **Dorsal digital artery:** Supplies the great toe. Arises from the 1st dorsal metatarsal artery.
- **Dorsal digital veins:** Drain to the dorsal venous arch of the foot, which is in turn formed by the union of the dorsal metatarsal veins.

The dorsal venous arch and plantar venous arch communicate. These veins give rise to the great saphenous vein on the medial aspect and the small saphenous vein on the lateral aspect.

Clinical Relevance: Vessels of the foot and hand afford opportunities for local and systemic autonomic neuromodulation and hemodynamic regulation. Hemodynamic changes result from ting point needling and improve local circulation to the acral extremity. This may promote nerve health in cases of peripheral neuropathy. Nervi vasorum connect to higher centers and influence systemic sympathetic control as well. These connections help explain the clinical indications of LR 2 and LR 3 for sympathetic hyperactivity and fever, known as "Liver Fire" and "Excess Heat" in Chinese medicine.

Dorsal interosseous muscles receive arterial blood via segmental branches off of their respective dorsal metatarsal arteries. The dorsal metatarsal arteries originate from the dorsalis pedis artery and connect with the vascular network on the plantar foot through a proximal and dorsal perforating artery. Microangiopathy or other vascular failures in patients such as diabetic individuals can compromise circulation and limit collateral vessel support, should one channel become obstructed or damaged.[8]

Forefoot surgery risks injury of the arterial supply of the lesser metatarsal head, such as at LR 2. The dorsal and plantar metatarsal arteries form a vascular ring around the head and an extensive extraosseous arterial network. Small branches from this anastomosis enter the head; nutrient arteries travel

1st dorsal interosseous m
LR 2

Figure 12-5. The first dorsal interosseous muscle of the foot, shown here, resembles in structure and, perhaps, function that of the same muscle in the hand; i.e., activities strongly associated with muscular coordination and whole-body interrelationships, both somatic and autonomic.

along the cortex of the metaphysis near insertions of ligaments and joint capsules. Branches from the nutrient arteries send branches into the subchondral bone to provide intraosseous blood supply. Thus, osteotomies that strip the capsular region of the metatarsal heads may negatively impact the medial and lateral vessels supplying that section of bone.[9]

Venous ulcers on or near the toes occur in patients with chronic venous insufficiency secondary to local trauma or skeletal deformities.[10] Whereas arterial ulcers are found on protruding areas, venous ulcers appear in valleys between the digits or at the dorsal base of the toe, such as near LR 2. Foot veins may be affected by venous thrombosis similar to leg veins. Superficial veins in the foot may exhibit varicose degeneration and direct damage by intravenous drug abuse. Perforating vein incompetence also takes place in the foot. Normally, perforating veins support blood flow from deep to superficial veins. Pedal veins have few valves, making them susceptible to reflux.

Indications and Potential Point Combinations

- **Genitourinary conditions:** LR 2, SP 6, CV 3, BL 23, BL 32, GV 20.
- **Eye pain, redness, swelling:** LR 2, LR 3, TH 23, BL 2, GB 1.
- **Seizures:** LR 2, LR 3, GB 20, GV 20, ST 36, BL 10.
- **Headaches (especially behind the eyes):** LR 2, LI 4, BL 10, GB 20, GV 20.

Evidence-Based Applications

- Acupuncture stimulation of HT 8, BL 66, and LR 2 effectively reduced elevated body temperature induced by **bacterial inflammation,** in part by suppressing hypothalamic production of pro-inflammatory cytokines.[1]
- Manual acupuncture at LR 2, HT 8, or BL 66 resolved experimentally induced **fever** in rats.[2] The mechanism of action of the antipyretic actions of acupuncture may be mediated through the down-regulation of two cytokines, IL-6 and IL-1-beta.
- Acupuncture at CV 3, BL 23, BL 28, KI 3, SP 6, SP 9, LR 2 (or LR 3) provided effective prophylaxis of **recurrent lower urinary tract infection** in adult women.[3]
- Acupuncture at HT 7, BL 40, and other points as needed for reinforcement such as LR 2 and LR 3 effectively treated children exhibiting **nocturnal enuresis.**[4]
- Hemodynamic and psychophysical responses to acupuncture stimulation at LR 2, LR 3, and ST 44, as well as a nearby sham point (the Bafeng point at the web space between the 3rd and 4th toes), exhibited great overlap, resulting in **extensive deactivation of a limbic-paralimbic-neocortical network** connected functionally and structurally.[5] This argues against acupuncture point specificity and in favor of significant overlap in its brain effects.
- Stimulation of LR 2 produced significant **activation of motor function-related brain regions.** These sites included the caudate, claustrum, and cerebellum. The limbic system also showed activation in the medial frontal gyrus, cingulate gyrus, and fusiform gyrus.[11]
- Stimulation of LR 2 produces **acute and delayed patterns of neuronal activation** that may be differentiated with fMRI. Acute effects were seen as activation in the insula and parahippocampal gyrus; the amygdala remained activated after 19 minutes following stimulation of the acupuncture needle.

LR 3

Tai Chong "Great Rushing", "Large Surge", "Great Thoroughfare"

On the dorsum of the foot in a depression distal to the junction of the 1st and 2nd metatarsal bones. Locate by palpating the groove to its proximal limit until finding a depression between the adjacent metatarsals.

Muscles

- **1st dorsal interosseous muscle:** Abducts the digits and flexes the metatarsophalangeal joints.

Clinical Relevance: Deep intrinsic muscles of the foot such as the interosseous muscles support its strength and architecture.[29] They provide for fine motor manipulation under normal circumstances.

LR 3 is located midway along the shaft of the 2nd metatarsal in the belly of the 1st dorsal interosseous muscle; this site represents a homologue for LI 4 on the hand. Stimulating LR 3 and LI 4 together constitutes treating "The Four Gates" for autonomic harmony and rejuvenation.

Nerves

- **Deep peroneal nerve (L4-S1):** Supplies the skin on the adjoining sides of the 1st and 2nd toes. Also supplies the extensor digitorum brevis muscle and other muscles in the anterior compartment.
- **Lateral plantar nerve (S2-S3):** Supplies all dorsal interosseous muscles of the foot. A branch of the tibial nerve.

Clinical Relevance: The oblique inferior medial band of the inferior extensor retinaculum as well as the tendon of the extensor hallucis longus muscle may compress the deep peroneal (fibular) nerve proximal to LR 3.[30] This constitutes the anterior tarsal tunnel syndrome. Other sites of nerve compress include the site where the deep peroneal (fibular) nerve travels deep to the extensor hallucis brevis and along the superior edge of the inferior retinaculum where the extensor hallucis longus travels over the nerve. Dorsal osteophytes of the talonavicular joint or an os intermetatarseum may push the nerve against the retinaculum and produce problems. Most patients developing anterior tarsal tunnel syndrome report a history of trauma, commonly recurring ankle sprain. Plantarflexion and supination of the foot maximally stretches the nerve at the cranial ankle and over the talonavicular joint. Tight-fitting ski boots and shoes are additional risk factors. Pain from anterior tarsal tunnel syndrome follows the course of the nerve undergoing entrapment. That is, it extends over the dorsum of the foot and into the web space between the first and second metarsals (LR 2-LR 3 territory). Treatment calls for myofascial release of the soft tissue surrounding the ankle and especially at the cranial surface, along with laser therapy for soft tissue relaxation and nerve regeneration. Acupuncture at LR 2, LR 3, and ST 41 is also indicated.

The abundance of somatic and autonomic nerve fibers points on the digits offers ample opportunities for somatic and sympathetic neuromodulation. Sympathetic innervation to the foot travels along the peripheral nerves. By the time vessels in the foot reach the ankle, they have already received their sympathetic fibers from the peripheral nerves.[31] An extensive network of sympathetic nerves supplies the foot, as it does the hand.

Clinically, the deep peroneal (fibular) nerve may provide a stronger effect on autonomic regulation than its superficial counterpart. Consider, for example, the impact of ST 36 on the autonomic nervous system, derived largely from its deep peroneal (fibular) connections. LR 1, LR 2, and LR 3 continue in this tradition with some differences. ST 36 surrounds itself with a rich supply of muscle afferents whereas distal LR points live in tissue replete with nervi vasorum. Different afferent fibers activated during acupuncture and related techniques cause different neuromodulatory outcomes.

Like the ulnar nerve in the hand that supplies the dorsal interosseous muscles, the lateral plantar nerve supplies all of the foot's dorsal interosseous muscles. Resemblances between acupuncture points and neural control of the thoracic and pelvic limbs include more than merely anatomical similarities.

Fast-adapting afferents at LR 2 and LR 3, among other locations on the dorsal foot, demonstrate a significant coupling response with muscles of the thoracic limb.[32] Through these connections, cutaneous afferents from the foot have the capacity to influence kinesthesia, reflexes, and tactile perception in the thoracic limb. These findings suggest that cutaneous input from the foot may play an important role in coordinating interlimb activity. Clinical implications include acupuncture and related techniques for stroke recovery, spinal cord injury, degenerative neurologic conditions, and peripheral nerve injury. Clearly, LR 2 and LR 3 should be considered for supporting recovery of thoracic limb strength and coordination.

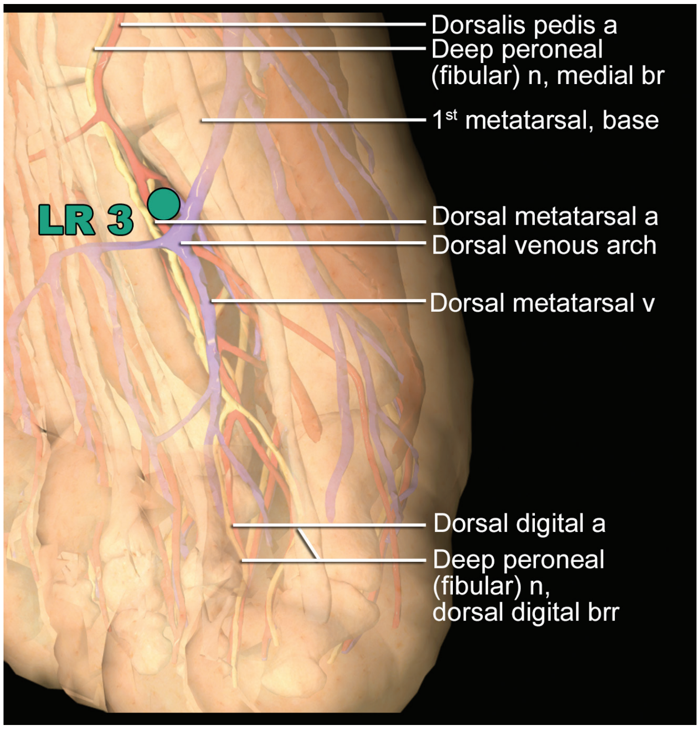

Figure 12-6. LR 3 resides at the intersection of the dorsal venous arch, the dorsal metatarsal artery running between the 1st and 2nd metatarsals, and a perforating arterial branch. Note the presence of the deep peroneal (fibular) nerve as well. This neurovascular traffic explains the reason behind the name "Great Thoroughfare" for LR 3.

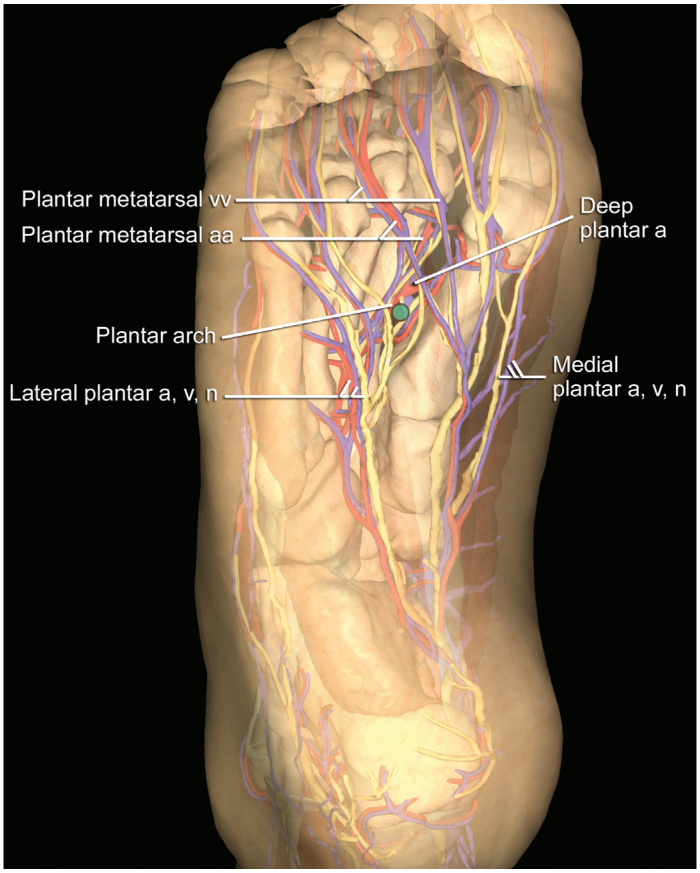

Figure 12-7. This view of the neurovascular architecture on the plantar foot and even the caudal heel and ankle describes in detail the sources of the nerves and vessels that literally "underlie" LR 3, though needled from above (shown as a blue-green circle). While one would not needle LR 3 deeply enough to access these vessels, they do connect to structures on the dorsal surface of the foot. Too, the double arterial arch system of the plantar foot becomes apparent here, mirroring a similar double arch system in the palmar hand, opposite LI 4.

Vessels

- **First dorsal metatarsal artery from the dorsalis pedis artery:** Branches into vessels that supply both sides of the great toe and the medial aspect of the 2nd toe.
- **Deep plantar artery:** Dives between the 1st and 2nd metatarsals to join the deep plantar arch.
- **Dorsal metatarsal veins:** Drain to the dorsal venous arch of the foot. The arch is, in turn, formed by the union of the dorsal metatarsal veins. The dorsal venous arch and plantar venous arch communicate. These veins give rise to the great saphenous vein on the medial aspect and the small saphenous vein on the lateral aspect.

Clinical Relevance: Vessels of the foot and hand afford opportunities for local and systemic autonomic neuromodulation and hemodynamic regulation. Hemodynamic changes result from ting point needling and improve local circulation to the acral extremity. This may promote nerve health in cases of peripheral neuropathy. Nervi vasorum connect to higher centers and influence systemic sympathetic control as well. These connections help explain the clinical indications of LR 2 and LR 3 for sympathetic hyperactivity and fever, known as "Liver Fire" and "Excess Heat" in Chinese medicine.

Dorsal interosseous muscles receive arterial blood via segmental branches off of their respective dorsal metatarsal arteries. The dorsal metatarsal arteries originate from the dorsalis pedis artery and connect with the vascular network on the plantar foot through a proximal and dorsal perforating artery. Microangiopathy or other vascular failures in patients such as diabetic individuals can compromise circulation and limit collateral vessel support, should one channel become obstructed or damaged.[33]

Forefoot surgery risks injury of the arterial supply of the lesser metatarsal head, such as at LR 2. The dorsal and plantar metatarsal arteries form a vascular ring around the head and an extensive extraosseous arterial network. Small branches from this anastomosis enter the head; nutrient arteries travel along the cortex of the metaphysis near insertions of ligaments and joint capsules. Branches from the nutrient arteries send branches into the subchondral bone to provide intraosseous blood supply. Thus, osteotomies that strip the capsular region of the metatarsal heads may negatively impact the medial and lateral vessels supplying that section of bone.[34] Treatment for this condition would include laser therapy and acupuncture in the immediate vicinity as well as at LR 3.

Venous ulcers on or near the toes occur in patients with chronic venous insufficiency secondary to local trauma or skeletal deformities.[35] Whereas arterial ulcers are found on protruding areas, venous ulcers appear in valleys between the digits or at the dorsal base of the toe, such as near LR 2. Foot veins may be affected by venous thrombosis similar to leg veins. Superficial veins in the foot may exhibit varicose degeneration and direct damage by intravenous drug abuse. Perforating vein incompetence also takes place in the foot. Normally, perforating veins support blood flow from deep to superficial veins. Pedal veins have few valves, making them susceptible to reflux. Treating this condition would call for a "surround the dragon" (i.e., circle the lesion) acupuncture in normal tissue at the perimeter of the problem, along with local laser therapy at appropriate power and wavelength and inclusion of LR 3 in the needling protocol.

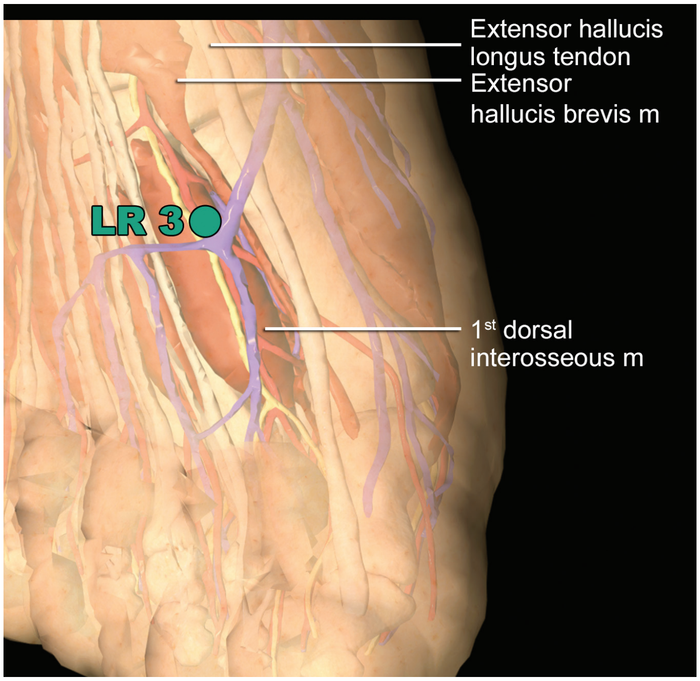
Indications and Potential Point Combinations

- **Liver or gallbladder disease:** LR 3, ST 36, GB 34, GB 24, LR 14, BL 18, BL 19.
- **Muscle tension in the foot, particularly on the dorsum along the groove between the 1st and 2nd metatarsal:** LR 3, LR 2, GB 36.
- **Nausea and vomiting:** LR 3, ST 36, PC 6.
- **Eye problems such as myopia, glaucoma, visual disorders:** LR 3, LI 4, ST 36, GB 1, TH 23, BL 9, BL 10.
- **Headaches related to allergies, particularly referring to the eye or vertex:** LR 3, LI 20, GB 14, ST 3, Yintang.
- **Insomnia:** LR 3, HT 3, HT 7, GV 20, ST 36.
- **Migraine headaches:** LR 3, LI 4, BL 10, GB 20, Taiyang, associated trigger points.
- **Irritability:** LR 3, HT 3, PC 6, GV 20.
- **Depression:** LR 3, LI 4, GV 20, Yintang, ST 36.
- **Seizures:** LR 3, KI 3,ST 36, GB 34, BL 10, BL 7, BL 8, GV 20.

- **Cold feet:** LR 3, LI 4, Bafeng, KI 3.
- **Endocrine and metabolic disorders:** LR 3, ST 36, GV 20, PC 6.
- **Premenstrual syndrome:** LR 3, SP 6, ST 36, GV 20, CV 2, CV 6, CV 12, LI 4, LI 11.

Evidence-Based Applications

- Case report indicated improvement with acupuncture at LR 3, KI 3, SP 6, and ST 36 for sweating **associated with malignancy** that was unresponsive to other measures.[1]
- Acupuncture at LR 3, SP 6, ST 36, CV 12, LI 4, PC 6, GB 20, GB 14, Taiyang, and GV 20 provided greater effectiveness in prophylaxis of **migraine** compared to flunarizine.[2]
- Acupuncture at LR 3, SP 6, LI 4, GB 20, GV 20, and Taiyang outperformed transcutaneous electrical nerve stimulation and laser therapy in reducing the frequency of **migraine**, although all three treatments were effective.[3]
- A case series involving acupuncture at LI 4, TH 5, LR 3, ST 36, ST 7, ST 6, and SI 17, splint therapy, and point injection therapy suggested that this combination was effective for managing **temporomandibular disorders.**[4]
- Electroacupuncture at LR 3, LI 4, GB 20, GB 21, and tender points provided relief of **myofascial pain in the upper trapezius muscle.**[36]
- Critically ill, postoperative pediatric patients found acupuncture at LR 3, LI 4, KI 3, and BL 60 to be a well tolerated and feasible **analgesic** method.[37]
- Acupuncture at SI 3, SI 14, LR 3, BL 10, BL 60, GB 20, GB 34, TH 5, trapezius myofascial trigger point, and the auricular point “cervical spine” provided greater pain relief of **chronic neck pain** compared to massage, but not sham laser.[5]
- Acupuncture at ST 36, SP 6, SP 9, LR 3, KI 3, BL 23, and BL 28 improved symptoms of **recurrent cystitis** in women.[6]
- Acupuncture at CV 3, BL 23, BL 28, KI 3, SP 6, SP 9, LR 2 (or LR 3) provided effective prophylaxis of **recurrent lower urinary tract infection** in adult women.[7]
- Both laser and needle acupuncture at GB 1, BL 2, ST 5, Yintang, LI 4, SI 3, LR 3, KI 6, and TH 5 worked equally well in improving objective measurements of **(keratoconjunctivitis sicca, or KCS).**[8]
- A case series reported that both acupuncture and moxibustion at BL 23, BL 32, BL 54, SP 6, CV 3, CV 4, KI 12, and LR 3 were effective in treating **erectile dysfunction.**[9]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in improvement in **sperm quality,** specifically in the ultrastructural integrity of spermatozoa.[10]
- Acupuncture at LU 9, ST 36, ST 40, SP 1, SI 3, BL 15, LR 3, CV 12, and CV 14 induced long-lasting reductions in attacks of primary **Raynaud’s syndrome,** demonstrated effectiveness comparable to nifedipine, and did so without adverse effects.[11]
- Acupuncture using magnetic needles at LI 11, ST 40, and LR 3 **lowered endothelin-1,** a potent vasoconstrictive peptide.[12]
- A case report indicated that acupuncture at ST 36, KI 3, and LR 3 produced dramatic improvement in **chronic venous ulceration.**[13]
- Acupuncture at LI 4, LR 3, and PC 6 inhibited sympathetic activation during mental stress in **advanced heart failure** patients.[14]



Extensor hallucis longus tendon
Extensor hallucis brevis m
LR 3
1st dorsal interosseous m

Figure 12-8. LR 3 and LI 4, known as the “Four Gates” in Chinese medicine, act as acupuncture homologues based on their anatomical similarity. This image highlights the bulk of the first dorsal interosseous muscle as it accepts a needle entering LR 3, as would the homologous muscle on the hand at LI 4.

- Acupuncture at LR 3, SP 6, SP 9, and ST 36 benefited patients with **chronic painful peripheral diabetic neuropathy.**[15]
- **HIV-related peripheral neuropathy** improved with electroacupuncture on BL 60, ST 36, KI 1, and LR 3.[16]
- Focused ultrasound stimulation of LR 3 increases blood flow in the brachial artery whereas LR 3 decreased blood flow volume.[38] This may be due to change in **peripheral vascular resistance** from needling at LR 3.[39]
- GB 34 and LR 3 delivered neuroprotective effects against neuronal death in a **Parkinson’s disease** model.[17]
- Acupuncture at LR 3, LI 4, GV 20, Yintang, as well as ear acupuncture produced as much benefit for **depressive neurosis** as Prozac and with fewer side effects.[18]
- Acupuncture at LR 3, LI 4, GB 20, Yintang, HT 7, PC 6, GV 20, GV 24, and GV 26 significantly benefited patients with **post-stroke anxiety neurosis.**[19]
- Acupuncture at various points including LR 3 may facilitate **post-exercise recovery and improve exercise performance.**[40]
- Acupuncture at LR 3, SP 6, LI 4, LI 11, GV 20, ST 36, and CV 2, CV 6, CV12 reduced complaints of myalgia, mastalgia, and dysmenorrhea in women with **premenstrual syndrome.** Acupuncture also increased nitric oxide levels in the blood.[41]
- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly **improved postmenopausal hot flushes and sweating episodes.**[20]
- Transcutaneous electrical nerve stimulation at SP 6 and LR 3 significantly increased the frequency and strength of uterine contractions in **post-dates pregnant women.**[21]
- Acupuncture at LI 4, LI 11, LR 3, SP 6, ST 25, ST 27, and ST 36 improved well-being and reduced bloating in patients **with**

irritable bowel syndrome.[22]

- Acupuncture at LR 3, ST 36, HT 7, and CV 12 produced better effects on **"gastrointestinal neurosis"** than the control medication.[23]
- Acupuncture at ST 36 and LR 3 significantly reduced liver injury markers when rats were acupunctured after, but not before, **CCL4-induced hepatotoxicity.**[24]
- A study evaluating the effects on cortical activation during stimulation of left LR 3 and left GB 40 revealed that, compared to the non-rotating stimulation method, rotating stimulation caused an increase in activation in both **secondary somatosensory cortical areas, frontal areas, the right thalamus and the left side of the cerebellum.** Stimulation of sham points did not strengthen the effects of acupuncture on brain activation.[25]
- Laserneedle® stimulation of LR 3 increased **cerebral blood flow** through the posterior cerebral artery but not the anterior cerebral artery.[42]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with idiopathic **oligoasthenoteratozoospermia** (OAT syndrome).[26]
- Acupuncture at GV 20 and LR 3, local points, and either BL 60+SI 3, BL 22 –> BL 26, the gluteus minimus tendon, or the symphysis pubis, provided effective relief of **pelvic and low back pain in late pregnancy.**[27]
- Acupuncture at LI 4, ST 36, PC 6, LR 3, CV 12, CV 17, and CV 22 successfully treated sleep-related laryngospasm with **gastroesophageal reflux,** refractory to current medical treatment; results were maintained at a 1-year follow-up assessment, and no evidence of reflux was detected upon repeated upper gastrointestinal study.[28]

LR 4

Zhong Feng "Mound Center", "Middle Seal", "Suspended Spring"

On the dorsum of the foot, approximately 1 cun cranial to the tip of the medial malleolus, in the depression medial to the tendon of the tibialis anterior muscle. Dorsiflex the foot before locating this point. Can also be found by determining the midpoint between SP 5 and ST 41. Examine these relationships in Figure 12-11.

Connective Tissues

- **Anterior tibiotalar and tibionavicular ligaments:** Four medial ligaments fan out from the tibia's medial malleolus. They attach to the talus, calcaneus, and navicular bones. These ligaments include the anterior and posterior tibiotalar, the tibionavicular, and the tibiocalcaneal ligaments. Collectively, they are also called the deltoid ligament.

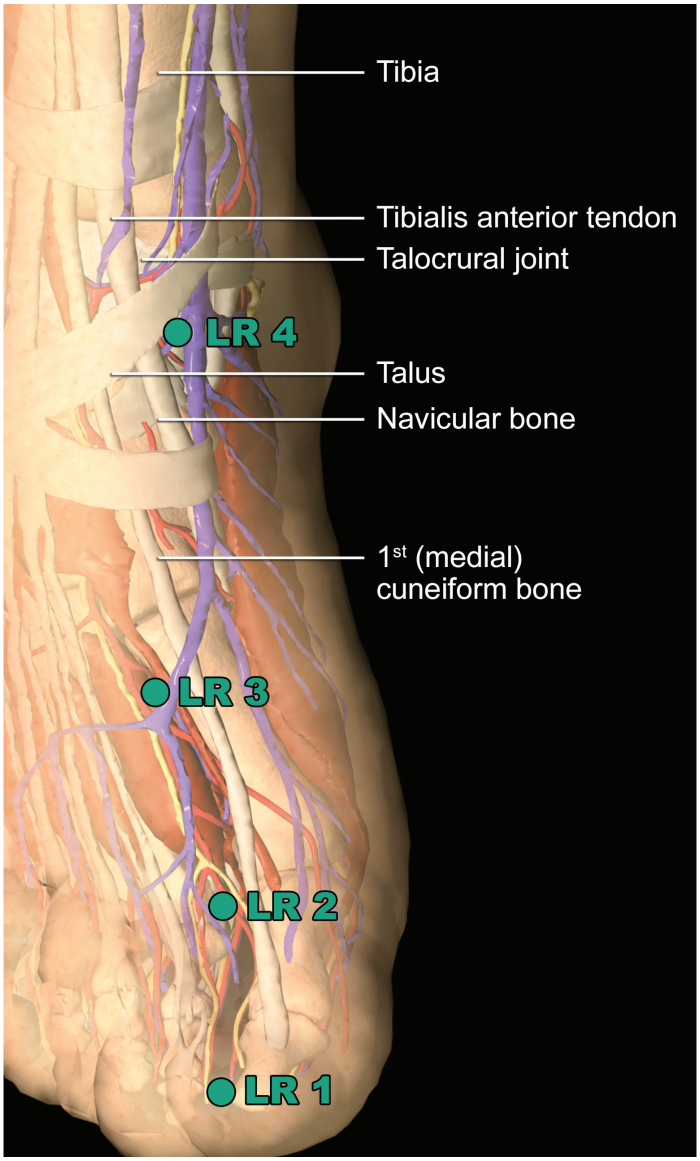

Figure 12-10. LR 4 relates to the talofibular and talocrural joints, as well as the great saphenous vein, shown here adjacent to the point. The "mound" upon which LR 4 ("Mound Center") rests is the ankle; LR 4 resides at a central location. An alternate name of "Suspended Spring" pertains to the saphenous vein suspended here from above. Located between the saphenous vein and the anterior tibialis tendon, LR 4, is "sealed".

Clinical Relevance: Joint stability requires fine interactions of static and dynamic components.[1] The aforementioned ligaments along with joint surface congruity limit joint translation while proprioceptive control over compressive and directional forces fall under the purview of nerves. Ligaments house mechanoreceptors, including Ruffini endings, Pacinian corpuscles, and Golgi-like endings (rare), as well as free nerve endings and various unclassifiable corpuscles. Sensory corpuscles and blood vessels occur, for the most part, close to ligamentous insertions onto bone, along with epiligamentous areas that provide support for the neurovascular bundles traveling into the ligament. Because most ligamentous disruption occurs in areas lacking neurovascular structures, proprioceptors and vessels are spared and thus can help heal a rupture ligament. Partial deafferentation of a ligament caused by damage to the sensory endings in the joint capsule and ligament may induce a functional instability in the ankle joint, leading to loss of position sense, reduced strength, delayed reaction time, and impaired control over posture. Acupuncture directed at restoring appropriate sensory input in periarticular structures at locations such as LR 4 may aid in restoring proprioceptive sensitivity to augment stabilization of the ankle joint.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: The distal saphenous nerve at the ankle may be injured during arthroscopy, fixation of distal tibia medial malleolar fractures, invasive approach to tarsal tunnel syndrome, and other surgical approaches to the ankle.[2]

Vessels

- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh, begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch, and anastomoses with the small saphenous vein and empties into the femoral vein.
- **Medial malleolar arterial network:** Provides blood supply to the medial malleolar region.
- **Medial malleolar venous network:** Drains the medial malleolar region.

Clinical Relevance: Sympathetic fibers travel with the peripheral nerves to supply arteries and larger veins with nervi vasorum.[3]

The great saphenous vein is often targeted during procedures designed to treat varicose veins. Stripping of the great saphenous vein may lead to saphenous nerve injury.[4] Should saphenous nerve injury occur, acupuncture and related techniques may aid in the recovery of this peripheral nerve.

Indications and Potential Point Combinations

- **Ankle pain:** LR 4, assess for trigger points causing referred pain, including one at ST 36 in the tibialis anterior that sends pain to the dorsal ankle and the big toe.

Figure 12-12. This cross-section through the ankle at this level shows the relationship between LR 4 and adjacent structures.

LR 5

Li Gou "Woodworm Canal"

On the medial crus, on the caudal border of the tibia, 5 cun proximal to the most prominent part of the medial malleolus. Because the distance between the popliteal crease and the tip of the medial malleolus measures 15 cun, one can find LR 5 at the junction of the middle and distal thirds in a depression between the tibia and the gastrocnemius muscle.

Muscles

- **Flexor digitorum longus muscle:** Flexes the lateral four pedal digits and plantarflexes the ankle. Helps support the longitudinal arch of the foot.
- **Posterior tibialis muscle:** Inverts the foot and provides ankle plantarflexion.

Clinical Relevance: Trigger point pathology in the flexor digitorum longus near LR 6 refers pain down the LR and SP channel to the medial malleolus as well as to the central plantar region of the foot. Deep needling at LR 5 may access a trigger point in the flexor hallucis longus, which refers pain to the plantar aspect of the great toe and first metatarsal. The long flexor muscles of the toes, i.e., the flexor digitorum and hallucis longus muscles, can participate in the development of "claw toes". Medial ankle pain and suspected tarsal tunnel syndrome may in actuality represent referred pain from long extrinsic flexor muscle trigger point pathology.

Trigger points in the tibialis posterior typically arise in the caudal calf but could pose problems at LR 5 as well. Referred pain from the tibialis posterior issues a pain pattern from about BL 57 to the calcaneal tendon and across over the entire plantar foot.

Nerves

- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: Indications for LR 5 related to genitourinary problems arise from the association of the tibial nerve with spinal cord segments that supply not only the somatic tissues at LR 5 but also genitourinary organs.

Venous structures of the pelvic limb may compress nerves, owing to their anatomical, vascular, and muscular relationships, especially in the standing position.[2] While microsurgery provides one course of action, acupuncture, laser therapy, and massage may aid patients suffering from saphenous nerve entrapment and obviate the need for surgery.

The saphenous nerve is subject to compression at a variety of sites along the medial pelvic limb; the nerve originates

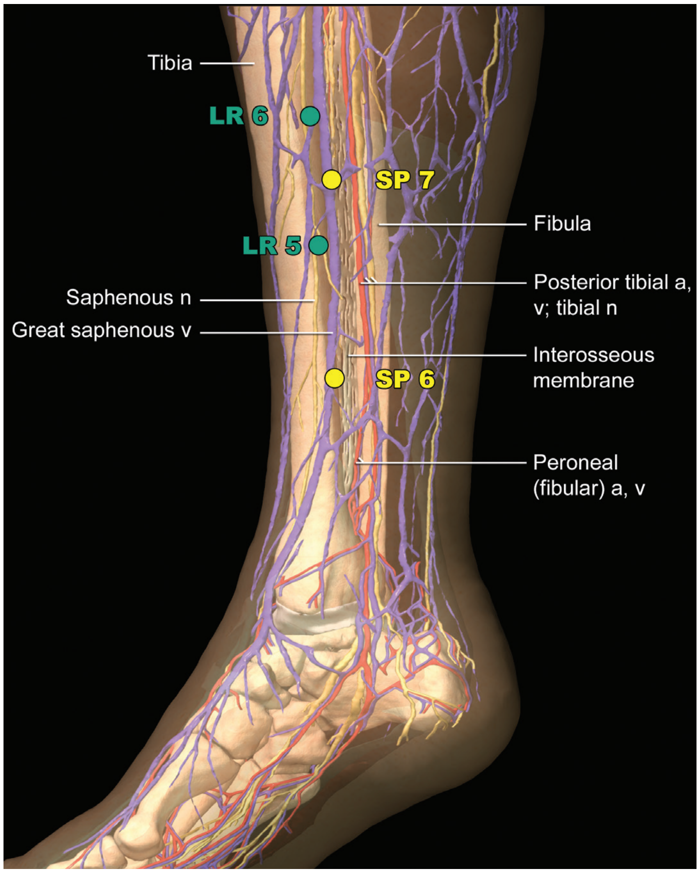

Figure 12-13. The LR and SP lines share territory over the saphenous nerve and great saphenous vein. Their overlapping indications for genitourinary conditions and saphenous nerve injury speak to their receiving innervation by the tibial and saphenous nerves, respectively.

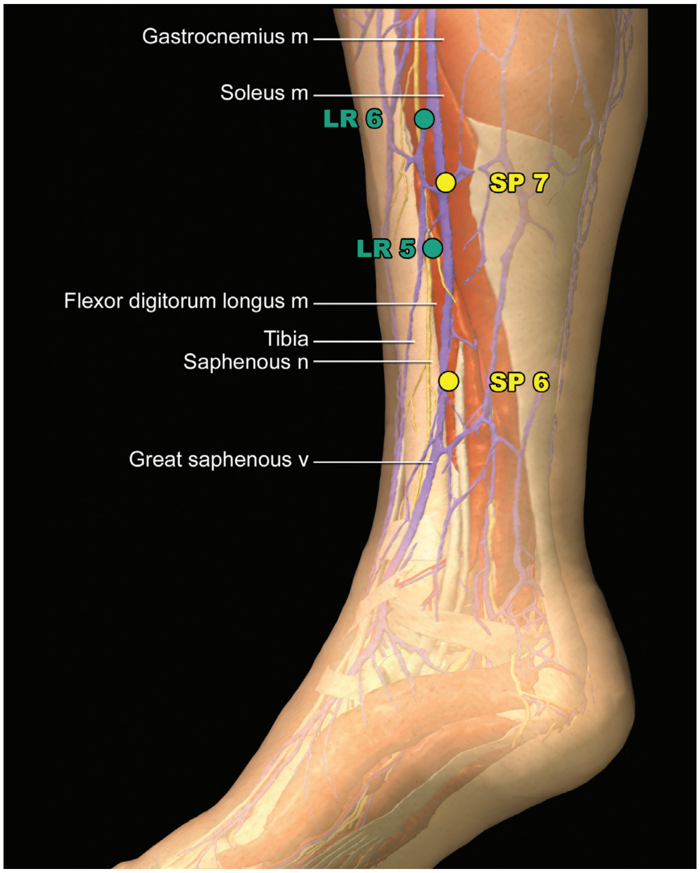

Figure 12-14. The name for LR 5 of "Woodworm Canal" refers to a hole made by a woodworm, similar to the small depression in which one locates LR 5. This "hole" appears as the flexor digitorum longus begins to disappear caudal to the tibia.

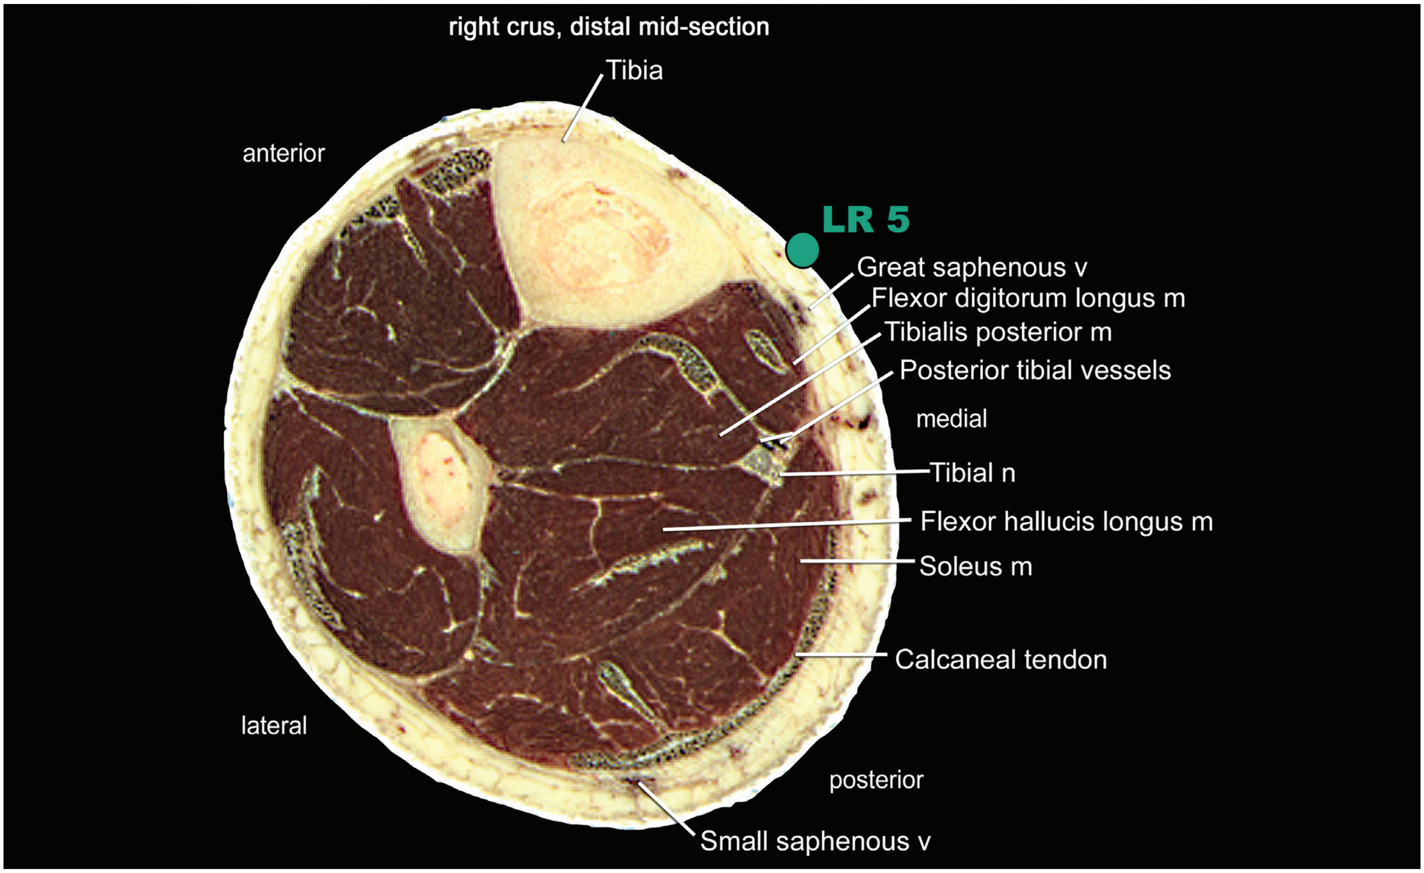

Figure 12-15. This cross-section exposes the way in which LR 5 provides a "direct hit" at the flexor digitorum longus muscle and, more deeply, the tibialis posterior. Trigger point pathology in either muscle can produce pain in the plantar aspect of the foot, causing the patient to believe she has plantar fasciitis when, in fact, she is harboring trigger points in the calf.

distal to the inguinal ligament, courses through the femoral triangle, and then accompanies the femoral vessels through the adductor canal.[3] The saphenous nerve then takes a more superficial course between the sartorius and gracilis muscles after penetrating the fascia lata. From here, the saphenous nerve travels on the medial aspect of the pelvic limb in the company of the great saphenous vein. An infrapatellar branch exits the adductor canal to supply the craniomedial knee. Here, the nerve supplies both the skin and the patellar ligament. The remainder of the saphenous nerve follows the great saphenous vein to the distal limb. Two branches form on the distal medial crus, becoming the medial and lateral crural cutaneous branches. The former communicates with cutaneous branches of the femoral nerve on the craniomedial crus. The lateral crural cutaneous branch descends between the anterior tibialis tendon and the medial malleolus, lateral to the great saphenous vein. This branch supplies sensation to the dorsal foot, medial malleolus, and skin of the first metatarsal head, abutting that supplied by the deep peroneal (fibular) nerve between LR 2 and LR 3.

The first locus of saphenous nerve entrapment occurs distal to the adductor canal where the saphenous nerve becomes superficial. Further down the limb, the infrapatellar branch may be injured or truncated during total knee replacement or other knee surgery that entails approaching the knee through a long incision that coincides with the nerve. Scar tissue may damage remaining branches. In other cases, compression or injury of the saphenous nerve causes acute and chronic medial knee pain. More distal compression of the saphenous nerve may refer pain proximad to the infrapatellar branch, leading to diagnostic and localizing ambiguity. Varicose vein surgery is a well-known culprit of saphenous nerve damage given how closely yet irregularly the nerve and great saphenous vein interrelate along their journeys. Removal of the great saphenous vein for use in coronary artery bypass surgery is perhaps the most common cause of saphenous nerve damage in the limb.

The differential diagnosis for saphenous nerve entrapment includes: medial meniscal tear, patellofemoral disorder, suprapatellar plica, pes tendinopathy, osteochondritis dissecans, nonspecific synovitis, and reflex sympathetic dystrophy.[4] Additional differentials include syndromes of the saphenous vein such as venous insufficiency and phlebitis; nerve root compression, arterial pathology, and knee or hip arthritis.[5]

Nonsurgical methods of treatment for saphenous nerve impingement pain and sensory disturbance should be tried prior to surgery.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and peroneal (fibular) veins.

- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh, begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch, and anastomoses with the small saphenous vein and empties into the femoral vein. A rich, mixed, vascular network (vasa vasorum) and attendant nerve accompany the great saphenous vein from ankle to knee.[6]
- **Perforating veins:** These veins contain valves that allow flow from the superficial to the deep veins. Perforating veins pass through deep fascia close to their origin off of the superficial veins. When they do so, they travel at an oblique angle so that muscular contraction and pressure within the compartment compresses the perforating veins. This phenomenon assists in encouraging unidirectional blood flow from superficial to deep veins and enables muscular contraction to assist in returning venous blood toward the heart, against the force of gravity.

Clinical Relevance: Stripping of the great saphenous vein may injure the saphenous nerve, leading to sensory dysfunction along the medial calf. The two structures have a close but variable relationship, making iatrogenic injury of the latter a complication of endovenous laser therapy and radiofrequency ablation.[7]

Indications and Potential Point Combinations

- **Genitourinary disorders, including: genital pain, genital itching, dysmenorrhea, orchitis, leukorrhea, urethritis, dysuria, urinary retention, enuresis:** LR 5, LR 12, SP 6, CV 2, CV 4.
- **Aching and pain in the crus:** Medial calf pain referred from the long flexors of the toes indicating trigger points in this muscle; add LR 6, LR 5, LR 2, SP 2, SP 3, acupressure at KI 1.
- **Saphenous nerve entrapment:** LR 5, LR 4; palpate along the entire course of the saphenous nerve to determine locus and cause of entrapment.
- **Medial knee pain:** LR 5, LR 8, LR 9, SP 9, relevant trigger points. Rule out neuropathy of the saphenous nerve, infrapatellar branch, before considering surgery for the knee when patients complain of medial knee pain!

Evidence-Based Applications

- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[1]
- Acupuncture at LR 5 plus movement therapy outperformed conventional acupuncture for **cervical spondylosis.**[8]

LR 6

Zhong Du “Central Metropolis”

On the medial leg, along the caudal border of the tibia, 7 cun proximal to the most prominent part of the medial malleolus. Divide the distance between the popliteal crease and the tip of the medial malleolus into two; locate LR 6 0.5 cun distal to this midpoint, between the medial border of the tibia and the gastrocnemius muscle. Note its position relative to LR 5 in Figures 12-13 and 12-14.

Muscles

- **Flexor digitorum longus muscle:** Flexes the lateral four pedal digits and plantarflexes the ankle. Helps support the longitudinal arch of the foot.
- **Posterior tibialis muscle:** Inverts the foot and provides ankle plantarflexion.

Clinical Relevance: Trigger point pathology in the flexor digitorum longus near LR 6 refers pain down the LR and SP channel to the medial malleolus as well as to the central plantar region of the foot. The long flexor muscles of the toes, i.e., the flexor digitorum and hallucis longus muscles, can participate in the development of “claw toes”. Medial ankle pain and suspected tarsal tunnel syndrome may in actuality represent referred pain from long extrinsic flexor muscle trigger point pathology.

Trigger points in the tibialis posterior typically arise in the caudal calf at the level of LR 6 or over SP and BL channel territory. Referred pain from the tibialis posterior leads to a pain pattern from the trigger point site (somewhere between LR 5 and BL 57) to the calcaneal tendon and across over the entire plantar foot.

Nerves

- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: Indications for LR 6 related to genitourinary problems arise from the association of the tibial nerve with spinal cord segments that supply not only the somatic tissues at LR 6 but also genitourinary organs.

Venous structures of the pelvic limb may compress nerves, owing to their anatomical, vascular, and muscular relationships, especially in the standing position.[1] While microsurgery provides one course of action, acupuncture, laser therapy, and massage may aid patients suffering from saphenous nerve entrapment and obviate the need for surgery.

The saphenous nerve is subject to compression at a variety of sites along the medial pelvic limb; the nerve originates distal to the inguinal ligament, courses through the femoral triangle, and then accompanies the femoral vessels through the adductor canal.[2] The saphenous nerve then takes a more superficial course between the sartorius and gracilis muscles after penetrating the fascia lata. From here, the saphenous nerve travels on the medial aspect of the pelvic limb in the company of the great saphenous vein. An infrapatellar branch exits the adductor canal to supply the craniomedial knee. Here, the nerve supplies both the skin and the patellar ligament. The remainder of the saphenous nerve follows the great saphenous vein to the distal limb. Two branches form on the distal medial crus, becoming the medial and lateral crural cutaneous branches. The former communicates with cutaneous branches of the femoral nerve on the craniomedial crus. The lateral crural cutaneous branch descends between the anterior tibialis tendon and the medial malleolus, lateral to the great saphenous vein. This supplies sensation to the dorsal foot, medial malleolus, and skin of the first metatarsal head, abutting that supplied by the deep peroneal (fibular) nerve between LR 2 and LR 3.

The first locus of saphenous nerve entrapment occurs distal to the adductor canal where the saphenous nerve becomes superficial. Further down the limb, the infrapatellar branch may be injured or truncated during total knee replacement or other knee surgery that entails approaching the knee through a long incision that coincides with the nerve. Scar tissue may damage

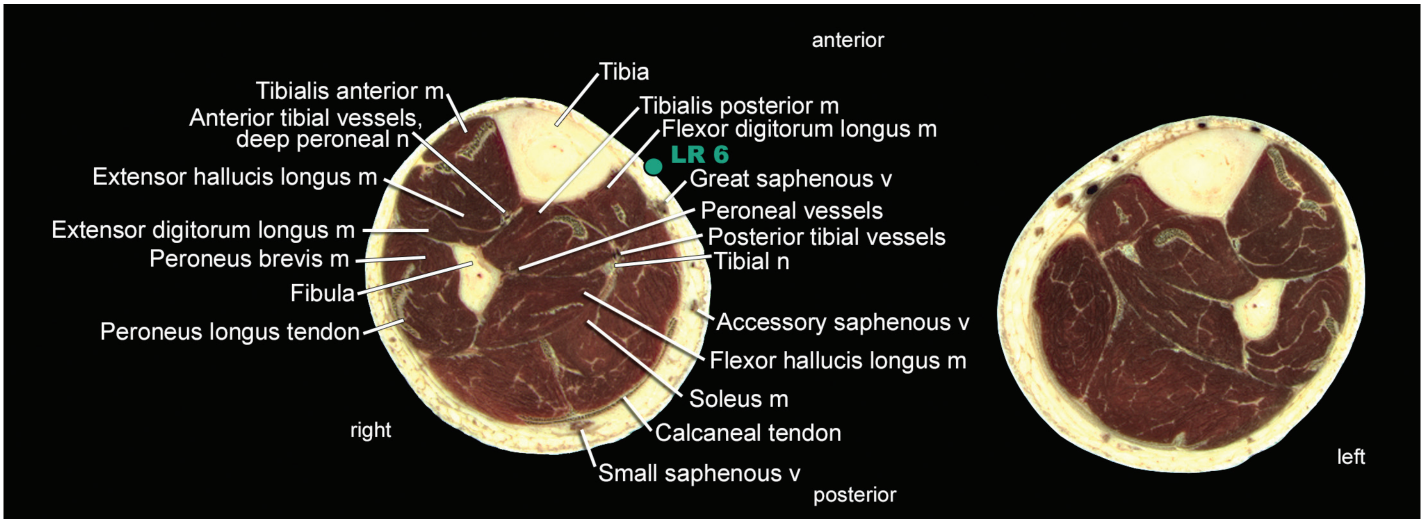

Figure 12-16. This cross section at the level of LR 6 shows the point sitting squarely atop the flexor digitorum longus muscle and, more deeply, the tibialis posterior muscle. Trigger points in either structure can cause the patient to feel pain in the calf, ankle, or plantar foot. Many cases of suspected plantar fasciitis are actually referred pain syndromes from trigger point pathology in the calf. Make sure to palpate the entire calf and foot exploring for trigger points before recommending invasive procedures for plantar fasciitis, as the assumption that the problem is in the foot may be incorrect.

remaining branches. In other cases, compression or injury of the saphenous nerve causes acute and chronic medial knee pain. More distal compression of the saphenous nerve may refer pain proximad to the infrapatellar branch, leading to diagnostic and localizing ambiguity. Varicose vein surgery is a well-known culprit of saphenous nerve damage given how closely yet irregularly the nerve and great saphenous vein interrelate along their journeys. Removal of the great saphenous vein for use in coronary artery bypass surgery is perhaps the most common cause of saphenous nerve damage in the limb.

The differential diagnosis for saphenous nerve entrapment includes: medial meniscal tear, patellofemoral disorder, suprapatellar plica, pes tendinopathy, osteochondritis dessicans, nonspecific synovitis, and reflex sympathetic dystrophy.[3] Additional differentials include syndromes of the saphenous vein such as venous insufficiency and phlebitis; nerve root compression, arterial pathology, and knee or hip arthritis.[4]

Nonsurgical methods of treatment for saphenous nerve impingement pain and sensory disturbance should be tried prior to surgery.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and peroneal (fibular) veins.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh, begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch, and anastomoses with the small saphenous vein and empties into the femoral vein. A rich, mixed, vascular network (vasa vasorum) and attendant nerve accompany the great saphenous vein from ankle to knee.[5]
- **Perforating veins:** These veins contain valves that allow flow from the superficial to the deep veins. Perforating veins pass through deep fascia close to their origin off of the superficial veins. When they do so, they travel at an oblique angle so that muscular contraction and pressure within the compartment compresses the perforating veins. This phenomenon assists in encouraging unidirectional blood flow from superficial to deep veins and enables muscular contraction to assist in returning venous blood toward the heart, against the force of gravity.

Clinical Relevance: Stripping of the great saphenous vein may injure the saphenous nerve, leading to sensory dysfunction along the medial calf. The two structures have a close but variable relationship, making iatrogenic injury of the latter a complication of endovenous laser therapy and radiofrequency ablation.[6]

Indications and Potential Point Combinations

- **Genitourinary disorders, including: genital pain, genital itching, dysmenorrhea, orchitis, leukorrhea, urethritis, dysuria, urinary retention, enuresis:** LR 5, LR 6, LR 12, SP 6, CV 2, CV 4.
- **Aching and pain in the crus:** Medial calf pain referred from the long flexors of the toes indicating trigger points in this muscle; add LR 6, LR 5, LR 2, SP 2, SP 3, acupressure at KI 1.

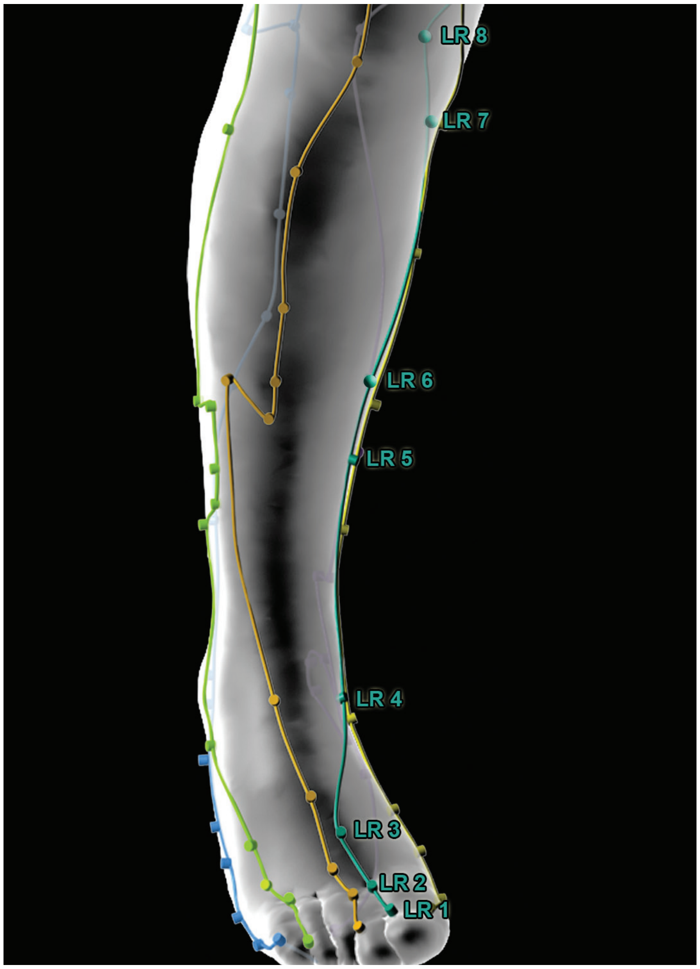

Figure 12-17. The name for LR 6, "Central Metropolis", refers to its location about midway along the crus in a busy, point-rich section of the leg. Many other points coexist in this region, including ST 38, ST 39, and ST 40 (shown in orange) and GB 35 and GB 36, in lime green. SP 7 is peeking around the corner medial and distal to LR 6 in shaded yellow.

- **Saphenous nerve entrapment:** LR 6, LR 4; palpate along the entire course of the saphenous nerve to determine locus and cause of entrapment.
- **Medial knee pain:** LR 6, LR 8, LR 9, SP 9, relevant trigger points. Rule out neuropathy of the saphenous nerve, infrapatellar branch, before considering surgery for the knee when patients complain of medial knee pain!
- **Heel pain:** Examine the soleus for a trigger point at LR 6 and/or LR 5.

LR 7

Xi Guan "Knee Joint", "Passageway to the Knee"

Caudal and distal to the medial condyle of the tibia, 1 cun caudal to SP 9, in the proximal portion of the medial head of the gastrocnemius muscle.

Muscles

- **Gastrocnemius muscle:** Plantarflexes the ankle when the knee is extended, raises the heel during ambulation, and flexes the leg at the knee joint.
- **Popliteus muscle:** Weakly flexes the knee and "unlocks" it by rotating the femur in a lateral direction atop the tibial plateau. Adheres to the joint capsule of the knee. Considered the "cornerstone stabilizer" of the posterolateral aspect of the knee in conjunction with its tendon, fascicles, and meniscocapsular attachment sites.[1] For the normal, intact lateral meniscus, the popliteus muscle acts as a retractor.[2]

Clinical Relevance: A trigger point in the gastrocnemius muscle at LR 7 send pain proximad and distad along the caudal thigh and calf, respectively. Referred pain extends to the plantar midfoot, mimicking plantar fasciitis pain like the long digitial flexors can. Myofascial trigger point pathology causes the calf to cramp, especially at night.

Trigger points in the popliteus muscle at or near LR 7 produce pain in the popliteal fossa and caudodistal femur over the medial epicondyle. Neuromodulation applied to structures around the knee such as the popliteus muscle has the potential to improve proprioception and general stability in conjunction with neuromuscular retraining. The popliteus muscle monitors and controls subtle movements in the knee, tantamount to a three-dimensional dynamic guidance system.[3] The popliteus musculotendinous complex and adjoining structures stabilize the knee by monitoring and controlling tibial external rotation, posterior translation during eccentric function (protecting the posterior cruciate ligament), and by causing tibial internal rotation and posterior translation during concentric function (protecting the anterior cruciate ligament). In short, LR 7 represents an access point through which to influence popliteus function.

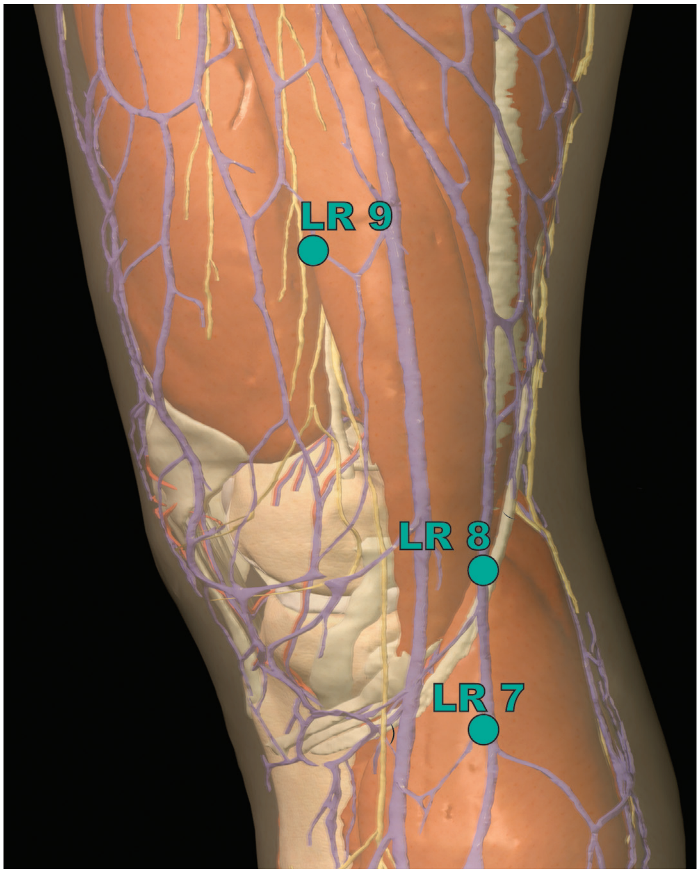

Figure 12-18. The descriptive name for LR 7, "Knee Joint", describes its proximity to the joint.

Nerves

- **Tibial nerve (L4, L5, S1, and S2):** The S1 and S2 branches innervate the plantaris, soleus, and gastrocnemius muscles, while the L4, L5, and S1 branches innervate the popliteus muscle.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: Tibial nerve branches may differ in terms of the spinal cord segments from which they originate. For example, S1 and S2 course in the tibial nerve branches to the gastrocnemius, soleus, and plantaris. L4 and L5 supply the tibialis posterior, while L4, L5, and S1 course to the popliteus. S2 and S3 supply the flexor hallucis longus and flexor digitorum longus. Thus, when employing points innervated by the tibial nerve for somatovisceral influence (e.g., when treating voiding dysfunction), more distal structures receive more caudal spinal segmental supply (i.e., from sacral cord segments). This explains why points along the LR, SP, and KI channels appear more routinely in needling formulae for voiding dysfunction than, for example, BL 40 or BL 55, which would be supplied by more cranial spinal segments that have a less direct relationship with the pelvic organs than do more caudal spinal segments. Thus, indications for LR 7 related to genitourinary problems arise from the association of the tibial nerve with spinal cord segments that supply not only the somatic tissues at LR 7 but also genitourinary organs.

Tibial nerve entrapment produces gastrocnemius muscle atrophy as well as paresthesia and pain from the neuropathy that ensues.

Venous structures of the pelvic limb may compress nerves, owing to their anatomical, vascular, and muscular relationships, especially in the standing position.[4] While microsurgery provides one course of action, acupuncture, laser therapy, and massage may aid patients suffering from saphenous nerve entrapment and obviate the need for surgery.

The saphenous nerve is subject to compression at a variety of sites along the medial pelvic limb; the nerve originates distal to the inguinal ligament, courses through the femoral triangle, and then accompanies the femoral vessels through the adductor canal.[5] The saphenous nerve then takes a more superficial course between the sartorius and gracilis muscles after penetrating the fascia lata. From here, the saphenous nerve travels on the medial aspect of the pelvic limb in the company

of the great saphenous vein. An infrapatellar branch exits the adductor canal to supply the craniomedial knee. Here, the nerve supplies both the skin and the patellar ligament. The remainder of the saphenous nerve follows the great saphenous vein to the distal limb. Two branches form on the distal medial crus, becoming the medial and lateral crural cutaneous branches. The former communicates with cutaneous branches of the femoral nerve on the craniomedial crus. The lateral crural cutaneous branch descends between the anterior tibialis tendon and the medial malleolus, lateral to the great saphenous vein. This supplies sensation to the dorsal foot, medial malleolus, and skin of the first metatarsal head, abutting that supplied by the deep peroneal (fibular) nerve between LR 2 and LR 3.

The first locus of saphenous nerve entrapment occurs distal to the adductor canal where the saphenous nerve becomes superficial. Further down the limb, the infrapatellar branch may be injured or truncated during total knee replacement or other knee surgery that entails approaching the knee through a long incision that coincides with the nerve. Scar tissue may damage remaining branches. In other cases, compression or injury of the saphenous nerve causes acute and chronic medial knee pain. More distal compression of the saphenous nerve may refer pain proximad to the infrapatellar branch, leading to diagnostic and localizing ambiguity. Varicose vein surgery is a well-known culprit of saphenous nerve damage given how closely yet irregularly the nerve and great saphenous vein interrelate along their journeys. Removal of the great saphenous vein for use in coronary artery bypass surgery is perhaps the most common cause of saphenous nerve damage in the limb.

The differential diagnosis for saphenous nerve entrapment includes: medial meniscal tear, patellofemoral disorder, suprapatellar plica, pes tendinopathy, osteochondritis dessicans, nonspecific synovitis, and reflex sympathetic dystrophy.[6] Additional differentials include syndromes of the saphenous vein such as venous insufficiency and phlebitis; nerve root compression, arterial pathology, and knee or hip arthritis.[7]

Nonsurgical methods of treatment for saphenous nerve impingement pain and sensory disturbance should be tried prior to surgery.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and peroneal (fibular) veins.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh, begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch, and anastomoses with the small saphenous vein and empties into the femoral vein. A rich, mixed, vascular network (vasa vasorum) and attendant nerve accompany the great saphenous vein from ankle to knee.[8]
- **Perforating veins:** These veins contain valves that allow flow

Figure 12-20. Deeply needled, LR 7 treats trigger points in both the gastrocnemius and popliteus muscles. Referred pain from a gastrocnemius trigger point covers the caudodistal thigh and caudal calf as well as focusing strongly on the plantar midfoot. A popliteus muscle trigger point centralizes pain in the popliteal fossa.

from the superficial to the deep veins. Perforating veins pass through deep fascia close to their origin off of the superficial veins. When they do so, they travel at an oblique angle so that muscular contraction and pressure within the compartment compresses the perforating veins. This phenomenon assists in encouraging unidirectional blood flow from superficial to deep veins and enables muscular contraction to assist in returning venous blood toward the heart, against the force of gravity.

Clinical Relevance: Stripping of the great saphenous vein may injure the saphenous nerve, leading to sensory dysfunction along the medial calf. The two structures have a close but variable relationship, making iatrogenic injury of the latter a complication of endovenous laser therapy and radiofrequency ablation.[9]

Indications and Potential Point Combinations

- **Medial knee pain, swelling, and inflammation:** Examine gastrocnemius for trigger points in the medial head at LR 7, BL 40, or KI 10. Also evaluate the popliteus muscle for a trigger point deeply located beneath LR 7, as shown in Figure 12-20.

LR 8

Qu Quan "Spring at the Crook", "Spring at the Bend"

Just proximal to the medial end of the popliteal crease, in a depression cranial to the tendons of the semimembranosus and semitendinosus muscles, caudal to the sartorius muscle. Locate with patient's knee flexed. About 1 cun cranial to KI 10. Have the patient flex the knee to locate the popliteal crease and to identify the semimembranosus and semitendinosus tendons. Review the relationship of the point to the tendons in Figure 12-22.

Muscles and Tendons

- **Sartorius muscle:** The sartorius flexes, laterally rotates, and abducts the thigh at the hip joint. Flexes the leg at the knee.
- **Gracilis tendon:** Flexes the leg, helps rotate it in a medial direction, and adducts the thigh.
- **Semitendinosus tendon:** Flexes the leg. Extends the thigh. When the knee is flexed, the semitendinosus muscle rotates the leg medially. Then the thigh and leg are flexed, the semitendinosus extends the trunk.

Clinical Relevance: The "pes anserinus" ("foot of the goose") on the leg embodies the insertion of the conjoined tendons of the sartorius, gracilis, and semitendinosus muscles at SP 9 after passing LR 8. The pes anserinus is superficial to the tibial insertion of the medial collateral ligament. The bursa that separates the pes anserinus from the medial collateral ligament may become inflamed or irritated from overuse or injury leading to pain, swelling, and tenderness to palpation. "Pes anserine bursitis" has been proposed as a cause of chronic knee pain and weakness; palpation of the knee and surrounding regions should help identify contributing factors and trigger point pathology. Although many patients with this problem are athletes, pes anserine bursitis or swelling in this region may represent an extra-articular manifestation of gout,[3] mineralized fibroma of the tendon sheath,[4] or cystic periarticular knee lesions. The source of knee pain at SP 9 or LR 8 may be ambiguous, meaning that the term "pes anserinus tendino-bursitis syndrome" may be inaccurate if other structures are indeed involved.[5] The syndrome involves pain in the medial aspect of the knee, especially when ascending or descending stairs, tenderness to palpation, and possibly local edema. Differential diagnosis includes medial meniscus injury, osteoarthritis of the medial knee, radiculopathy of the L3-L4 nerve roots, and medial collateral ligament lesion.

Nerves

- **Obturator nerve (L2-L4):** The obturator nerve branches into anterior and posterior branches. The anterior branch supplies adductor muscles, including the adductor longus and brevis muscles, the gracilis, and the pectineus muscles. The posterior branch supplies the adductor magnus and obturator externus muscles.
- **Femoral nerve (L2-L4):** The femoral nerve arises from the lumbar plexus and is its largest branch. Supplies the skin on the anteromedial thigh. Supplies the hip and knee joints and the anterior thigh muscles, including the sartorius muscle.
- **Sciatic nerve (L4-S3):** Supplies the hamstring muscles (i.e., the semimembranosus, semitendinosus, and long head of the biceps femoris muscles) by its tibial division (L5-S2).
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: Despite their common final destination, each muscle contributing to the pes anserinus carries a distinct innervation. That is, the femoral nerve supplies the sartorius, the obturator nerve innervates the gracilis, and the tibial portion of the sciatic nerve supplies the semitendinosus. Thus, needling

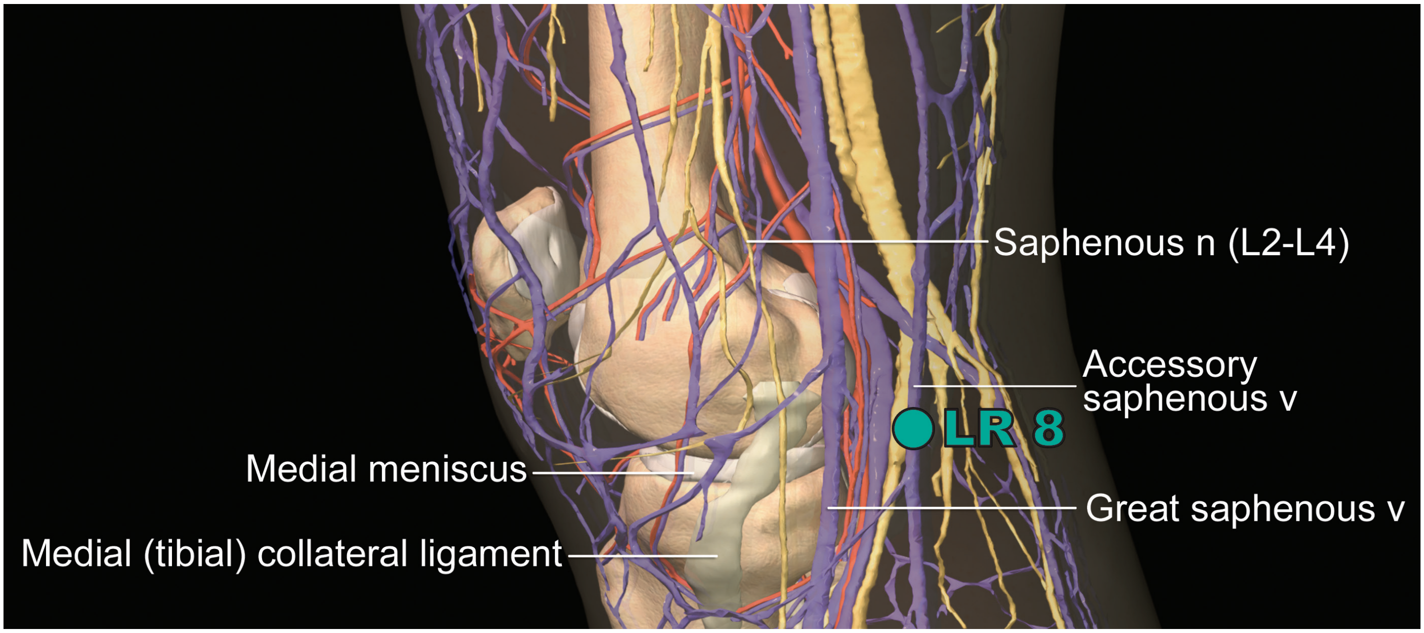

Figure 12-21. LR 8 is called "Spring at the Bend", signifying its relationship to the accessory saphenous vein (the "spring") level with the joint line (the "bend"). Other points around the knee with the term "spring" in their name include nearby GB 34 ("Yang Mound Spring") and SP 9 ("Yin Mound Spring").

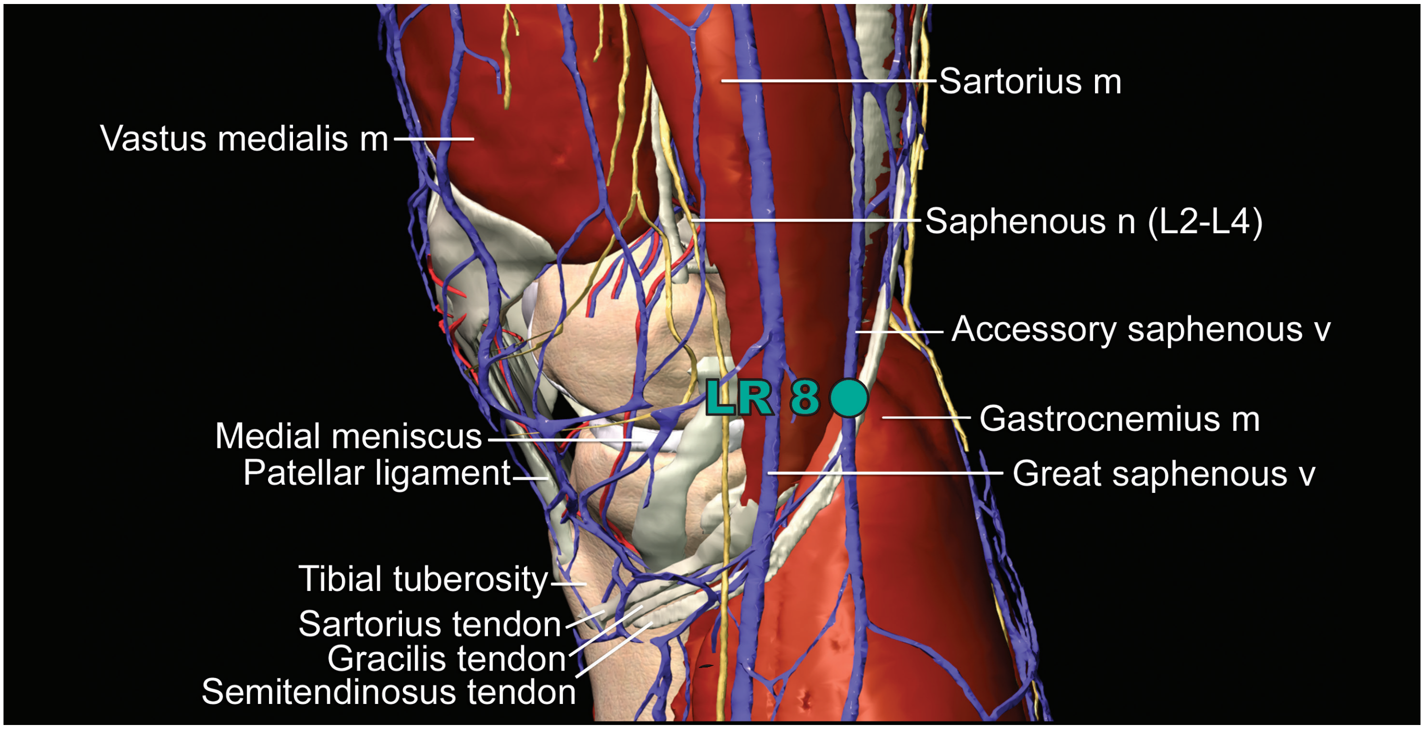

Figure 12-22. LR 8 lands along the myotendinous bundle destined to become the pes anserinus at SP 9. This structure contains a large number of mechanoreceptors that contribute to knee stability and position sense.

or otherwise stimulating the point LR 8, like SP 9, impacts three different myotendinous structures and their unique nerves.

John Hilton (1805-1878) was one of the first to note that patients with hip disease may also experience knee pain due to the common innervation of both joints.[6] He also lectured on his own "Hilton's Law", which states, "The same trunks of nerves, whose branches supply the groups of muscles moving a joint, furnish also a distribution of nerves to the skin over the insertions of the same muscles; and – what at this moment more especially merits our attention – the interior of the joint receives its nerves from the same source." Thus, the fact that the femoral, obturator, and tibial portion of the sciatic nerve all supply movers of the knee means, according to this law, that they each send branches to the overlying skin as well as the joint itself. This anatomical "law" highlights the relevance of SP 9 in treating disorders of the knee, including pain and proprioceptive abnormalities.

Venous structures of the pelvic limb may compress nerves, owing to their anatomical, vascular, and muscular relationships, especially in the standing position.[7] While microsurgery provides one course of action, acupuncture, laser therapy, and massage may aid patients suffering from saphenous nerve entrapment and obviate the need for surgery.

The saphenous nerve is subject to compression at a variety of sites along the medial pelvic limb; the nerve originates distal to the inguinal ligament, courses through the femoral triangle, and then accompanies the femoral vessels through the adductor canal.[8] The saphenous nerve then takes a more superficial course between the sartorius and gracilis muscles after penetrating the fascia lata. From here, the saphenous nerve travels on the medial aspect of the pelvic limb in the company of the great saphenous vein. An infrapatellar branch exits the adductor canal to supply the craniomedial knee. Here, the nerve supplies both the skin and the patellar ligament. The remainder of the saphenous nerve follows the great saphenous vein to the distal limb. Two branches form on the distal medial crus, becoming the medial and lateral crural cutaneous branches. The former communicates with cutaneous branches of the femoral nerve on the craniomedial crus. The lateral crural cutaneous branch descends between the anterior tibialis tendon and the medial malleolus, lateral to the great saphenous vein. This supplies sensation to the dorsal foot, medial malleolus, and skin of the first metatarsal head, abutting that supplied by the deep peroneal (fibular) nerve between LR 2 and LR 3.

The first locus of saphenous nerve entrapment occurs distal to the adductor canal where the saphenous nerve becomes superficial. Further down the limb, the infrapatellar branch may be injured or truncated during total knee replacement or other knee surgery that entails approaching the knee through a long incision that coincides with the nerve. Scar tissue may damage remaining branches. In other cases, compression or injury of the saphenous nerve causes acute and chronic medial knee pain. More distal compression of the saphenous nerve may refer pain proximad to the infrapatellar branch, leading to diagnostic and localizing ambiguity. Varicose vein surgery is a well-known culprit of saphenous nerve damage given how closely yet irregularly the nerve and great saphenous vein interrelate along their journeys. Removal of the great saphenous vein for use in coronary artery bypass surgery is perhaps the most common cause of saphenous nerve damage in the limb.

Saphenous neuropathy can cause knee pain.[9] Obesity, genu varum, and internal tibial torsion contribute to stress on the saphenous nerve. Symptoms of saphenous neuropathy include pain and paresthesia on the medial aspect of the knee. The differential diagnosis for saphenous nerve entrapment includes: medial meniscal tear, patellofemoral disorder, suprapatellar plica, pes tendinopathy, osteochondritis dessicans, nonspecific synovitis, and reflex sympathetic dystrophy.[10] Additional differentials include syndromes of the saphenous vein such as venous insufficiency and phlebitis; nerve root compression, arterial pathology, and knee or hip arthritis.[11]

Some patients complain of a "pulling" sensation during flexion and extension of the knee. Others remark that the area gives them an "unpleasant" sensation or a feeling of burning. On physical examination, the area over the infrapatellar branch of the saphenous nerve may have decreased sensation, dysesthesia, or hyperesthesia. Nonsurgical methods of treatment for saphenous nerve impingement pain and sensory disturbance should be tried prior to surgery. Acupuncture and related techniques designed to minimize nerve compression and entrapment from its origin at the femoral nerve and the femoral triangle to its destination, as well as to encourage restoration of normal function may aid in the conservative resolution of this disorder.

Vessels

- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh, begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch, and anastomoses with the small saphenous vein and empties into the femoral vein.
- **Superior medial genicular artery:** The superior medial genicular artery participates in the formation of the genicular anastomosis – a network of vessels around the knee. It does so with the help of the other genicular arteries, including the lateral superior, medial inferior, and lateral inferior arteries and three additional contributors: the descending genicular branch of the femoral artery, the descending branch of the lateral femoral circumflex artery, and the anterior recurrent branch of the anterior tibial artery. Genicular branches of the popliteal artery also supply the knee joint capsule and the ligaments of the knee.
- **Medial superior veins of the knee:** One of several deep veins around the knee that drain into the popliteal vein.

Clinical Relevance: Articular structures such as the knee receive abundant blood supply by means of anastomotic networks. However, numerous surgical procedures and trauma put the vascular supply of the patella at risk. They may acutely alter flow through direct vascular insult (e.g., pseudoaneurysm) or, over the long term, drive sympathetic nerve stimulation, peripheral or central nervous system sensitization in chronic pain states. Acupuncture in this region may aid in restoring proper circulation by neuromodulating nervi vasorum and central nervous system pathways.

Similarly, blood flow compromise to the patellar tendon may put that structure at risk of developing patellar tendinopathy and, conceivably, rupture.[12]

Perhaps most importantly, the anterior cruciate ligament and supporting structures derives its blood supply from the genicular periarticular vascular plexus.[13] Soft tissues within the knee (i.e., the infrapatellar fat pad and synovium) mediate the blood supply to both cruciate ligaments. As such, negative impacts to these sites may impair nutrition to the cruciate ligaments and contribute to their degradation.

Varicose saphenous veins contain unmyelinated C fibers in the external portion of the media as well as the internal part of the adventitia.[14] Histiocytes and other inflammatory cells exist scattered within the media. These findings provide evidence for the existence of a neurologic medium through which nociceptive signals from the vein reach the spinal cord and brain. Mast cells and concomitant inflammatory cells may serve to activate C fibers in the vessel wall of the varicose vein. The presence of nerves and inflammatory cells suggests an avenue through which neuromodulation through acupuncture and related techniques may impart healing effects for a disturbed milieu.

Indications and Potential Point Combinations

- **Medial knee pain:** LR 8, SP 10, SP 9, KI 10.
- **Cruciate ligament injury:** LR 8, BL 40, GB 33, ST 34, ST 35, ST 36, SP 10, SP 9. Consider electrical stimulation across the joint.

Evidence-Based Applications

- Laser acupuncture significantly outperformed sham laser for the treatment of **mild to moderate depression** with the following points: LR 8, LR 14, CV 14, CV 15, HT 7, SP 6, LI 4, and GV 20.[1]
- Laser acupuncture clinically statistically significantly reduced symptoms of **major depression** compared to placebo acupuncture. Points included LR 8, LR 14, KI 3, HT 7, and CV 14.[15] These same points increased brain activation in the frontal-limbic-striatal regions.[16]
- Electroacupuncture at 2 Hz reportedly **increased blood flow** in the spleen (but not the liver) and liver (but not the spleen) of rats when treating SP 9 and LR 8, respectively.[17]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV4, CV 6, and GV 4.[2]

LR 9

Yin Bao "Yin Wrapping", "Yin Wrappage", "Yin Bladder"

On the medial thigh, 4 cun proximal to the medial epicondyle of the femur and LR 8, in the cleft between the vastus medialis and sartorius muscles. (See Figure 12-24 for location.) (Alternate method: Starting at LR 8, slide a finger craniad across thebetween the vastus medialis and sartorius muscles to reach a tender spot within a depression.)

Connective Tissues

- **Vastoadductor membrane:** The vastoadductor membrane forms a subcompartment within the canal underlying the sartorius muscle, known as the "subsartorial canal".[1]

Clinical Relevance: This membrane connects the medial edge of the vastus medialis muscle to the lateral border of the adductor magnus muscle. In so doing it forms the roof of the adductor canal. (The adductor canal can be seen in cross section in Figure 12-25.)

Cutaneous branches of the saphenous and obturator nerves perforate the vastoadductor membrane. A number of vessels also course through this connective tissue, including communicating branches between the great saphenous and the deep venous system as well as muscular and cutaneous branches of the femoral artery.

Patients with spontaneous, nontraumatic, saphenous neuralgia secondary to saphenous nerve entrapment in the subsartorial canal present with medial knee and crus pain. These individuals report tenderness to palpation over the canal and sensory deficits along the saphenous nerve distribution.

Some have speculated that restless legs syndrome may result from entrapment of the saphenous nerve along its course, such as at adductor canal.

Increased stiffness and tension in the membrane may impair return of venous blood from the pelvic limb and worsen varicose veins.

Muscles and Tendons

- **Adductor magnus muscle:** Adducts the thigh. Comprises two parts – the adductor part and the hamstrings part. The adductor part flexes the thigh while the hamstrings part extends it.
- **Vastus medialis muscle:** Extends the leg at the knee joint. Extends the leg at the knee joint. Dubbed the "buckling knee muscle" by Travell and Simons, the vastus medialis harbors trigger points that not only cause pain but also inhibit muscle function, leading to unexpected failure of knee support.

Clinical Relevance: Trigger points in the adductor magnus and vastus medialis muscles refer pain along the LR and SP channels from LR 9 and SP 10 to the groin.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Anterior femoral cutaneous nerve (from the femoral nerve, L2-L4):** Supplies the skin on the anterior and medial Aspects of

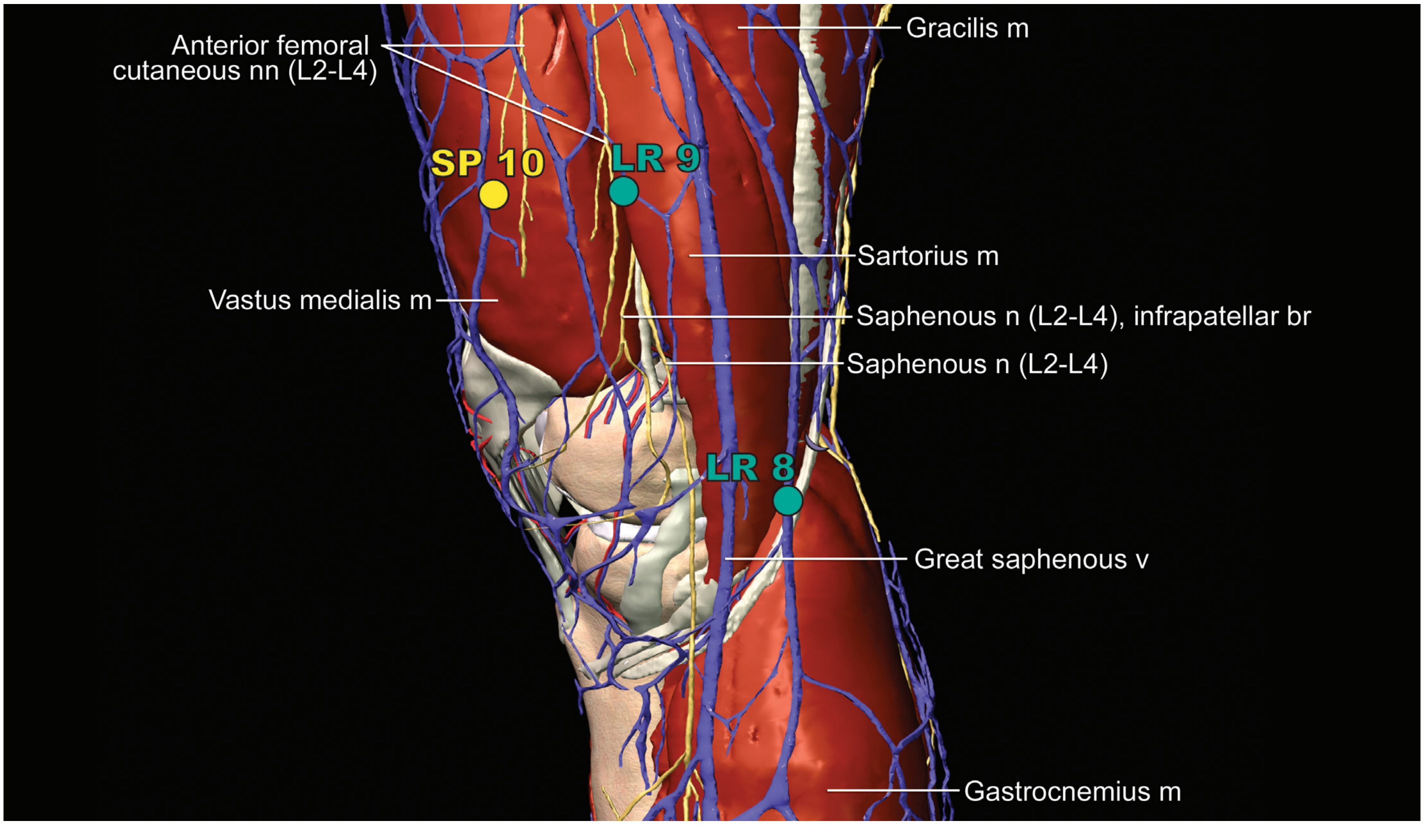

Figure 12-24. The sartorius adjacent to LR 9 resembles a fluid-filled bladder on the medial thigh that the ancient Chinese referred to as "Yin Bladder". The term "Yin Wrappage" connotes the way in which this muscle curves around the thigh on the medial ("Yin") surface.

the thigh.

- **Obturator nerve (L2-L4):** The obturator nerve branches into anterior and posterior branches. The anterior branch supplies adductor muscles, including the adductor longus and brevis muscles, the gracilis, and the pectineus muscles. The posterior branch supplies the adductor magnus and obturator externus muscles.
- **Femoral nerve (L2-L4):** The femoral nerve arises from the lumbar plexus and is its largest branch. Supplies the skin on the anteromedial thigh. Supplies the hip and knee joints and the anterior thigh muscles, including the sartorius muscle.

Clinical Relevance: Sites on the thigh where the saphenous nerve may become entrapped include 1) The adductor canal where the saphenous nerve splits from the femoral and courses independently along the fascial channel through the adductor canal, and 2). The locus where the nerve leaves the adductor canal to exit the fascial layer between the sartorius and gracilis muscles. Chronic irritation or compression may induce persistent, medial knee pain.[2] Palpating for myofascial restriction in the medial thigh should help localize the site of saphenous nerve compression or entrapment.

Vessels

- **Femoral artery:** Supplies the anteromedial surface of the thigh as well as the anterior surface.
- **Femoral vein:** The femoral vein arises from the popliteal vein.
- **Perforating veins:** Drain blood from the thigh muscles.
- **Deep vein of the thigh:** The perforating veins terminate in the deep vein of the thigh.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh, begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch, and anastomoses with the small saphenous vein and empties into the femoral vein.
- **Descending genicular artery, articular branch:** This artery arises from the femoral artery and gives rise to muscular and articular branches. It anastomoses with the superior and inferior medial genicular arteries. The descending genicular artery passes through the opening in the adductor magnus tendon to divide into saphenous and articular branches. The saphenous branch of the descending genicular artery follows the saphenous nerve along the medial aspect of the knee and the LR channel. Articular branches anastomoses with the medial superior genicular artery within the substance of the vastus medialis muscle, not far from SP 10.

Clinical Relevance: Applying acupuncture, laser therapy, or soft tissue manual therapy could aid circulation by alleviating fascial restriction and neurovascular compression.

Indications and Potential Point Combinations

- **Saphenous neuralgia or neuropathy, restless leg syndrome, altered or painful sensation along the medial thigh and leg (SP and LR channels):** Consider entrapment by the vastoadductor membrane; palpate for restrictions and tenderness along the medial thigh and needle accordingly, including LR 9.
- **Genitourinary conditions:** LR 9, SP 6, CV 4, BL 23, BL 28, BL 32.

LR 10

Zu Wu Li "Leg Five Miles", "Foot Five Li"

On the craniomedial thigh, on the lateral border of the adductor longus muscle, 2 cun from its attachment to the pubic symphysis, approximately 3 cun distal to ST 30. (See Figure 12-27 to examine the relationship between LR 10, ST 30, and the pubic symphysis.) The adductor longus tendon is often the most prominent tendon in the groin, and originates on the pubic bone. Ask the patient to adduct the thigh slightly to activate the tendon to better define its location.

Note: This point is located very close to the apex of the femoral triangle where the femoral artery exits the triangle to enter the adductor canal. (Review the anatomy of the femoral triangle in Figure 12-26.)

Connective Tissues

- **Adductor canal:** This conical or pyramidal canal contains the femoral vessels, the saphenous nerve, and a certain amount of connective tissue. Its distal extent, the narrowest point, borders the vastoadductor membraine, the sartorius muscle, the vastus medialis, and the adductor magnus and longus muscles.[1]

Clinical Relevance: Compression of the neurovascular contents in the adductor canal by tense muscles and/or facial restriction causes clinical symptoms of neuralgia and circulatory impairment. Patients with spontaneous, nontraumatic, saphenous neuralgia secondary to saphenous nerve entrapment in the adductor canal present with medial knee and crus pain. These individuals report tenderness to palpation over the canal and sensory deficits along the course of the nerve.

Restless legs syndrome may result from entrapment of the saphenous nerve along its course, such as at adductor canal.

Chronic groin pain has many etiologies due to the multiplicity of anatomical structures in this region that experience injury or disease. Muscle strain affecting the adductors or pectineus, tendonitis, bursitis, osteitis pubis, inguinal hernia, sustained stressful postures, inguinal ligament enthesopathy, and peripheral nerve entrapment (e.g., obturator or lateral femoral cutaneous nerves) constitute examples of disorders that produce chronic groin pain.[2]

Determining the course of the extrapelvic portion of the obturator nerve is challenging due to the variability of nerve, vessel, and fascia in the adductor regions. Figures 12-26 and 12-27 delineate the network of nerves, arteries and veins in the adductor corridor. They are difficult to follow even in a photo – imagine the complexity of trying to sort these out surgically!

Muscles

- **Adductor longus muscle:** Adducts the thigh.
- **Adductor brevis muscle:** Adducts the thigh. Also assists in thigh flexion.
- **Adductor magnus muscle:** Adducts the thigh. Comprises two parts – the adductor part and the hamstrings part. The adductor part flexes the thigh while the hamstrings part extends it.
- **Pectineus muscle:** Adducts the thigh. Flexes the thigh. Helps medially rotate the thigh.

Clinical Relevance: Trigger points in the adductor magnus refer pain along the medial thigh that describes the course of the LR pathway. Myofascial dysfunction in the adductor magnus and brevis send pain more predominantly down the ST and SP lines to the knee, then with just the SP channel to the ankle.

Figure 12-27. This image of the deep muscles of the proximal pelvic limb exposes the complex neurovascular anatomy associated with LR 10, LR 11, and LR 12.

Travell and Simons call the pectineus muscle the "fourth adductor". Trigger point pathology produces pain in the local groin and proximal thigh region along the LR 10, LR 11, LR 12 corridor. Pain may refer to the lateral thigh into ST channel territory.

The posterior, or caudal, division of the obturator nerve in the proximal medial thigh both exits through the obturator externus muscle and supplies it as well. From there, the posterior branch courses cranial to the adductor magnus muscle, sending branches to that and its brevis counterpart. Terminal articular branches of the obturator nerve exit the adductor hiatus and enter the popliteal fossa whereupon they supply the articular capsule, cruciate ligaments, and synovial membrane of the knee joint. Pathology of the hip, such as slipped capital femoral epiphysis, may refer pain to the knee by dint of the innervation of both the hip and knee by the posterior division of the obturator nerve.

Nerves

- **Obturator nerve (L2-L4):** The obturator nerve branches into anterior and posterior branches. The anterior branch supplies adductor muscles, including the adductor longus and brevis muscles, the gracilis, and the pectineus muscles. The posterior branch supplies the adductor magnus, adductor brevis, and obturator externus muscles.
- **Femoral nerve (L2-L4):** The femoral nerve arises from the lumbar plexus and is its largest branch. Supplies the skin on the anteromedial thigh. Supplies the hip and knee joints and the anterior thigh muscles, including the sartorius muscle.
- **Anterior femoral cutaneous nerve (L2-L4, from the femoral nerve):** Innervates the skin on the anteromedial thigh.
- **Genitofemoral nerve (L1, L2):** Divides into genital and femoral branches. The femoral branch supplies the skin overlying the femoral triangle. The genital branch supplies the labia majora in females and the scrotum in males.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the pelvic limb.

Clinical Relevance: Sites of compression for the anterior division of the obturator nerve occur between pectineus and obturator externus muscles as well as between the adductor longus and brevis. The obturator nerve travels medial to the femoral nerve within the pelvis. Near to where the obturator nerve exits the pelvis through the obturator foramen, it divides into anterior and posterior branches. The anterior branch courses cranial to the obturator externus muscle while the posterior branch courses through it. The anterior division supplies motor innervation to the adductor longus, adductor brevis, pectineus, and gracilis muscles. It also sends sensory supply to the hip joint and medial thigh. The posterior branch supplies the adductor brevis, the adductor magnus, and the obturator externus. It provides sensation to the knee joint as well. Causes of obturator neuropathy include pelvic and acetabular fractures, post-traumatic hematoma, pelvic tumors, obturator hernia, myositis ossificans, penetrating or surgical trauma, and nerve compression by fibrous brands secondary to chronic adductor tendinopathy with osteitis pubis, more common in athletes.

Traumatic contusion or laceration may cause a saphenous neuropathy within the adductor canal due to the nerve's superficial location. The nerve courses deep to the sartorius muscle in an oblique craniocaudal direction. The saphenous nerve is subject to compression at a variety of sites along the medial pelvic limb; the nerve originates distal to the inguinal ligament, courses through the femoral triangle, and then accompanies the femoral vessels through the adductor canal.[3] The saphenous nerve then takes a more superficial course between the sartorius and gracilis muscles after penetrating the fascia lata. From here, the saphenous nerve travels on the medial aspect of the pelvic limb in the company of the great saphenous vein. An infrapatellar branch exits the adductor canal to supply the craniomedial knee. Here, the nerve supplies both the skin and the patellar ligament. The remainder of the saphenous nerve follows the great saphenous vein to the distal limb. Two branches form on the distal medial crus, becoming the medial and lateral crural cutaneous branches. The former communicates with cutaneous branches of the femoral nerve on the craniomedial crus. The lateral crural cutaneous branch descends between the anterior tibialis tendon and the medial malleolus, lateral to the great saphenous vein. This supplies sensation to the dorsal foot, medial malleolus, and skin of the first metatarsal head, abutting that supplied by the deep peroneal (fibular) nerve between LR 2 and LR 3.

The first locus of saphenous nerve entrapment occurs distal to the adductor canal where the saphenous nerve becomes superficial. Further down the limb, the infrapatellar branch may be injured or truncated during total knee replacement or other knee surgery that entails approaching the knee through a long incision that coincides with the nerve. Scar tissue may damage remaining branches. In other cases, compression or injury of the saphenous nerve causes acute and chronic medial knee pain. More distal compression of the saphenous nerve may refer pain proximad to the infrapatellar branch, leading to diagnostic and localizing ambiguity. Varicose vein surgery is a well-known culprit of saphenous nerve damage given how closely yet irregularly the nerve and great saphenous vein interrelate along their journeys. Removal of the great saphenous vein for use in coronary artery bypass surgery is perhaps the most common cause of saphenous nerve damage in the limb.

Saphenous neuropathy can cause knee pain.[4] Obesity, genu varum, and internal tibial torsion contribute to stress on the saphenous nerve. Symptoms of saphenous neuropathy include pain and paresthesia on the medial aspect of the knee. The differential diagnosis for saphenous nerve entrapment includes: medial meniscal tear, patellofemoral disorder, suprapatellar plica, pes tendinopathy, osteochondritis dessicans, nonspecific synovitis, and reflex sympathetic dystrophy.[5] Additional differentials include syndromes of the saphenous vein such as venous insufficiency and phlebitis; nerve root compression, arterial pathology, and knee or hip arthritis.[6]

Some patients complain of a "pulling" sensation during flexion and extension of the knee from saphenous neuropathy. Others remark that the area gives them an "unpleasant" sensation or a feeling of burning. On physical examination, the area over the infrapatellar branch of the saphenous nerve may have decreased sensation, dysesthesia, or hyperesthesia. Nonsurgical methods of treatment for saphenous nerve impingement pain and sensory disturbance should be tried prior to surgery. Acupuncture and related techniques designed to minimize nerve compression and entrapment from its origin at the femoral nerve and the femoral triangle to its destination, as well as to encourage restoration of normal function may aid in the conservative resolution of this disorder.

Iatrogenic procedures in the groin, along with blunt or penetrating trauma, may damage the genitofemoral and ilioinguinal nerves, producing persistent pain and paresthesias in the inguinal region.[7] Hyperextension of the hip and physical activity typically worsen the pain from genitofemoral neuropathy, which may extend to the genitalia and proximomedial thigh over LR 10, LR 11, and LR 12.

Vessels

- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh, begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch, and anastomoses with the small saphenous vein and empties into the femoral vein.
- **Medial circumflex femoral artery:** Supplies the majority of blood to the femoral head and neck.
- **Medial circumflex femoral vein:** Accompanies the medial circumflex femoral artery and terminates in either the femoral or deep femoral vein.
- **Femoral artery:** Supplies the anteromedial surface of the thigh as well as the anterior surface.
- **Femoral vein:** The femoral vein arises from the popliteal vein.

Clinical Relevance: Obturator neuropathy, i.e., focal obturator nerve entrapment, can be caused by both fascial and vascular compression.

In some individuals, the medial circumflex femoral artery and vein cross the caudal (or posterior) division of the obturator nerve as the latter descends within a fascial plane superficial to the obturator externus and proximal portion of the adductor magnus muscle.[8] Arterial anastomoses between the muscular branches of the medial circumflex artery and the anterior branch of the obturator happen here – vascular abnormalities could cause obturator nerve compression. The presence of vessels overlying the nerve as well as its "low visibility" in imaging studies creates difficulties for clinicians attempting obturator nerve blocks.

Fascial expansions such as perivascular condensations around vessels supplying the adductor musculature produce a definitive layer of connective tissue that may entrap the anterior division of the obturator nerve.[9] The vascular pedicle from the medial circumflex femoral artery that leads to the pectineus, adductor longus, and adductor brevis surrounds the obturator nerve as it courses toward the apex of the brevis, thereby diminishing space further for the nerve.

The femoral artery and vein enter the adductor canal close to LR 10, at the apex of the femoral triangle. The femoral triangle, bounded superiorly by the inguinal ligament, medially by the adductor longus, and laterally by the sartorius, rests upon a floor formed by the iliopsoas muscle and pectineus. The roof of this triangle is built by the fascia lata and cribriform fascia, along with subcutaneous tissue and skin. From lateral to medial, the contents of the femoral triangle include the femoral nerve and branches, the femoral sheath and contents, the femoral artery and branches, and the femoral vein and tributaries (e.g., the great saphenous and deep femoral veins). As such, LR 10 serves as an entryway to a high traffic zone replete with vessels and nerves of major importance.

Figure 12-28. A needle injudiciously inserted deeply into LR 10 could readily injure major vessels within the adductor canal. This, could cause adductor canal outlet syndrome, a condition in which mechanical trauma of the femoral artery tears the intimal layer, forming a localized thrombosis.[11]

Indications and Potential Point Combinations

- **Groin pain:** LR 10, ST 32; palpate the pectineus muscle for trigger points.
- **Knee pain and/or hip pain referred from the adductor longus and brevis muscles:** LR 10, GB 29, ST 31, ST 34, SP 10.

Evidence-Based Application

- Electroacupuncture at LR 10, LR 11, ST 31, and GB 29 more effectively alleviated pain from **hip osteoarthritis** and benefited joint function over diclofenac sodium.[10]

LR 11

Yin Lian "Yin Corner"

On the craniomedial thigh on the lateral margin of the adductor longus muscle or tendon, 1 cun from its attachment near the pubic symphysis, approximately 2 cun distal to ST 30. The adductor longus tendon is often the most prominent tendon in the groin, and originates on the pubic bone.

Muscles

- **Adductor longus muscle:** Adducts the thigh.
- **Adductor brevis muscle:** Adducts the thigh. Also assists in thigh flexion.
- **Pectineus muscle:** Adducts the thigh. Flexes the thigh. Helps medially rotate the thigh.

Clinical Relevance: Trigger points in the adductor magnus refer pain along the medial thigh that describes the course of the LR pathway. Myofascial dysfunction in the adductor magnus and brevis send pain more predominantly down the ST and SP lines to the knee, then with just the SP channel to the ankle.

Travell and Simons call the pectineus muscle the "fourth adductor". Trigger point pathology produces pain in the local groin and proximal thigh region along the LR 10, LR 11, LR 12 corridor. Pain may refer to the lateral thigh into ST channel territory. Patients may complain of hip pain but indicate the region immediately distal to the inguinal ligament; i.e., the pectineus muscle. The deep-seated groin pain caused by pectineus trigger points worsens with weight bearing and activities that require thigh abduction. This myofascial pathology often accompanies trigger points in the iliopsoas and the adductors.

The posterior, or caudal, division of the obturator nerve in the proximal medial thigh both exits through the obturator externus muscle and supplies it as well. From there, the posterior branch courses cranial to the adductor magnus muscle, sending branches to that and its brevis counterpart. Terminal articular branches of the obturator nerve exit the adductor hiatus and enter the popliteal fossa whereupon they supply the articular capsule, cruciate ligaments, and synovial membrane of the knee joint. Pathology of the hip, such as slipped capital femoral epiphysis, may refer pain to the knee by dint of the innervation of both the hip and knee by the posterior division of the obturator nerve.

Nerves

- **Obturator nerve (L2-L4):** The obturator nerve branches into anterior and posterior branches. The anterior branch supplies adductor muscles, including the adductor longus and brevis muscles, the gracilis, and the pectineus muscles. The posterior branch supplies the adductor magnus and obturator externus muscles.
- **Genitofemoral nerve (L1, L2):** Divides into genital and femoral branches. The femoral branch supplies the skin overlying the femoral triangle. The genital branch supplies the labia majora in females and the scrotum in males.

Clinical Relevance: Sites of compression for the anterior division of the obturator nerve occur between pectineus and obturator externus muscles as well as between the adductor longus and brevis. The obturator nerve travels medial to the femoral nerve within the pelvis. Near to where the obturator nerve exits the pelvis through the obturator foramen, it divides into anterior and posterior branches. The anterior branch courses cranial to the obturator externus muscle while the posterior branch courses through it. The anterior division supplies motor innervation to the adductor longus, adductor brevis, pectineus, and

Figure 12-30. Reaching the pectineus through the femoral triangle requires careful localization and avoidance of the triangle's neurovascular contents. LR 11 nestles in the "Yin Corner", at the medial thigh where the leg meets the groin.

gracilis muscles. It also sends sensory supply to the hip joint and medial thigh. The posterior branch supplies the adductor brevis, the adductor magnus, and the obturator externus. It provides sensation to the knee joint as well. Causes of obturator neuropathy include pelvic and acetabular fractures, post-traumatic hematoma, pelvic tumors, obturator hernia, myositis ossificans, penetrating or surgical trauma, and nerve compression by fibrous brands secondary to chronic adductor tendinopathy with osteitis pubis, more common in athletes.

Iatrogenic procedures in the groin, along with blunt or penetrating trauma, may damage the genitofemoral and ilioinguinal nerves, producing persistent pain and paresthesias in the inguinal region.[1] Hyperextension of the hip and physical activity typically worsen the pain from genitofemoral neuropathy, which may extend to the genitalia and proximomedial thigh over LR 10, LR 11, and LR 12.

Vessels

- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh, begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch, and anastomoses with the small saphenous vein and empties into the femoral vein.
- **Femoral artery:** Supplies the anteromedial surface of the thigh as well as the anterior surface.
- **Femoral vein:** The femoral vein arises from the popliteal vein.
- **Medial circumflex femoral artery:** Supplies the majority of blood to the femoral head and neck.
- **Medial circumflex femoral vein:** Accompanies the medial circumflex femoral artery and terminates in either the femoral or deep femoral vein.

Clinical Relevance: Obturator neuropathy, i.e., focal obturator nerve entrapment, can be caused by both fascial and vascular compression.

In some individuals, the medial circumflex femoral artery and vein cross the caudal (or posterior) division of the obturator nerve as the latter descends within a fascial plane superficial to the obturator externus and proximal portion of the adductor magnus muscle.[2] Arterial anastomoses between the muscular branches of the medial circumflex artery and the anterior branch of the obturator happen here – vascular abnormalities could cause obturator nerve compression. The presence of vessels overlying the nerve as well as its "low visibility" in imaging studies creates difficulties for clinicians attempting obturator nerve blocks.

Fascial expansions such as perivascular condensations around vessels supplying the adductor musculature produce a definitive layer of connective tissue that may entrap the anterior division of the obturator nerve.[3] The vascular pedicle from the medial circumflex femoral artery that leads to the pectineus, adductor longus, and adductor brevis surrounds the obturator nerve as it courses toward the apex of the brevis, thereby diminishing space further for the nerve.

The femoral artery and vein enter the adductor canal close to LR 10, at the apex of the femoral triangle. The femoral triangle, bounded superiorly by the inguinal ligament (not shown here), medially by the adductor longus, and laterally by the sartorius, rests upon a floor formed by the iliopsoas muscle and pectineus. The roof of this triangle is built by the fascia lata and cribriform fascia, along with subcutaneous tissue and skin. From lateral to medial, the contents of the femoral triangle include the femoral nerve and branches, the femoral sheath and contents, the femoral artery and branches, and the femoral vein and tributaries (e.g., the great saphenous and deep femoral veins). As such, LR 10 and LR 11 serve as entryways to a high traffic zone replete with vessels and nerves of major importance.

Indications and Potential Point Combinations

- **Thigh or groin pain related to pectineus trigger points:** LR 11; consider adding GB 26, GB 27, and GB 28 for concomitant iliopsoas restriction and local trigger points in the adductors to address their contribution to perceived hip or groin pain distal to the inguinal ligament.
- **Vulvodynia, scrotal pain:** LR 11, SP 12, ST 30, CV 2, GV 3, BL 23.

Evidence-Based Application

- Electroacupuncture at LR 10, LR 11, ST 31, and GB 29 more effectively alleviated pain from **hip osteoarthritis** and benefited joint function over diclofenac sodium.[4]

LR 12

Ji Mai "Urgent Pulse"

On the base of the femoral triangle, distal to the inguinal Ligament and medial to the pulsation of the femoral artery.

Approximately 1 cun distal to and 2.5 cun lateral to the midline and CV 2.

Although some sources have described an alternate location for LR 12 cranial to the inguinal ligament and lateral to ST 30, treating that site would target different muscles, nerves, and vessels, thereby changing its clinical relevance and expected physiologic outcomes.

Note in Figure 12-33 the presence of the spermatic cord and large vessels within reach of a needling entering LR 12. Needle with caution in this region.

Muscles

- **Pectineus muscle:** Adducts the thigh. Flexes the thigh. Assists in rotating the thigh mediad.
- **Obturator externus muscle:** Adducts the thigh. Rotates the thigh laterad.
- **Obturator internus muscle:** Adducts the thigh when the hip flexes. Rotates the thigh laterad.

Clinical Relevance: Based on the cross section shown in Firgure 12-33, the pectineus muscle is the straight-on myofascial target of LR 12. Travell and Simons call the pectineus muscle the "fourth adductor". Trigger point pathology in the pectineus produces pain in the local groin and proximal thigh region along the LR 10, LR 11, LR 12 corridor. Pain may refer to the lateral thigh; i.e., ST channel territory. Patients may complain of hip pain but indicate the region immediately distal to the inguinal ligament; i.e., the pectineus muscle. The deep-seated groin pain caused by pectineus trigger points worsens with weight bearing and activities that require thigh abduction. This myofascial pathology often accompanies trigger points in the iliopsoas and the adductors.

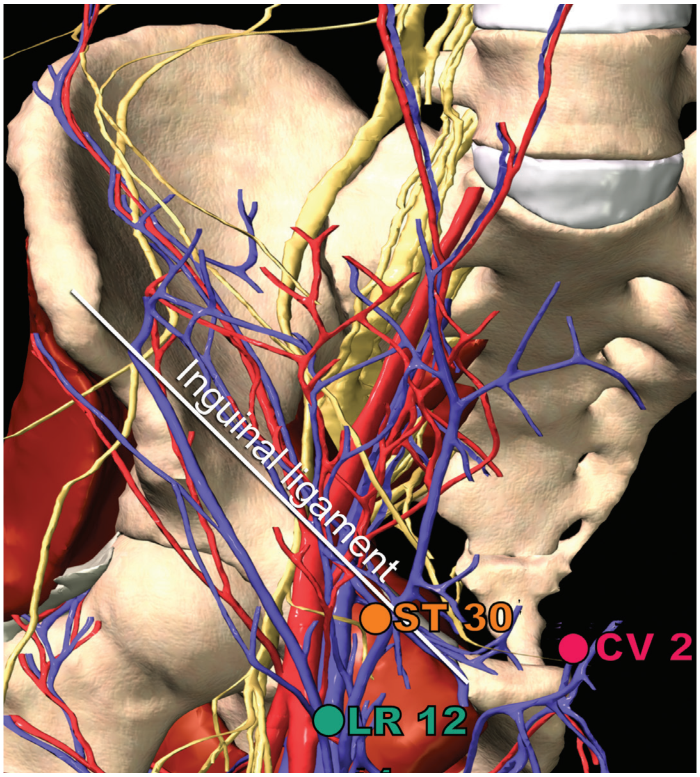

Figure 12-31. The "Urgent Pulse", i.e., the sensation appreciated when palpating the femoral artery, illustrates the ancient association between blood vessels and acupuncture channels. As seen in this image, LR 12 sits immediately adjacent to the femoral artery, between the "urgent pulse" and the femoral vein.

The posterior, or caudal, division of the obturator nerve in the proximal medial thigh both exits through the obturator externus muscle and supplies it as well. From there, the posterior branch courses cranial to the adductor magnus muscle, sending branches to that and its brevis counterpart. Terminal articular branches of the obturator nerve exit the adductor hiatus and enter the popliteal fossa whereupon they supply the articular capsule, cruciate ligaments, and synovial membrane of the knee joint. Pathology affecting the hip, such as slipped capital femoral epiphysis, may refer pain to the knee by dint of the innervation of both the hip and knee by the posterior division of the obturator nerve.

A trigger point in the obturator externus muscle can cause right lower abdominal wall pain near the inguinal ligament. Pain may radiate to the groin and proximal medial thigh. A burning sensation may accompany the pain. Discomfort can worsen when the patient drives or crosses the pelvic limbs.

The obturator internus muscle, along with its compatriots that create the pelvic diaphragm (i.e., bulbospongiosus, ischiocavernosus, transversus perinei, sphincter ani, levator ani, and the coccygeus) produce what Travell and Simons call a "pain in the rear". That is, they refer pain to the intergluteal cleft and perianal area. Trigger point pathology in the obturator internus may refer pain along the caudal thigh overlying sciatic nerve terrain.

While both obturator muscles fall in line with LR 12, treatment of their trigger points may be more safely instituted with manual trigger point release and stretching of the trunk, hip, and pelvic myofascial elements, rather than the extremely deep needling that it would require at LR 12, jeopardizing safety.

Nerves

- **Obturator nerve (L2-L4):** The obturator nerve branches into anterior and posterior branches. The anterior branch supplies adductor muscles, including the adductor longus and brevis muscles, the gracilis, and the pectineus muscles. The posterior branch supplies the adductor magnus and obturator externus muscles.
- **Genitofemoral nerve (L1, L2):** Divides into genital and femoral branches. The femoral branch supplies the skin overlying the femoral triangle. The genital branch supplies the labia majora in females and the scrotum in males.
- **Ilioinguinal nerve (L1, occasionally with T12):** Branches from the ilioinguinal nerve supply the skin of the scrotum and labium majus by means of its anterior scrotal and labial branches, respectively. Other branches supply the skin over the proximal and medial thigh. The ilioinguinal nerve accompanies the spermatic cord or round ligament of the uterus as it moves through the superficial inguinal ring, on the way to its destination of either the scrotum or labium majus. The ilioinguinal nerve is involved in the afferent limb of the cremasteric reflex, along with

the genitofemoral nerve (L1,L2). Branches of the ilioinguinal nerve include the anterior scrotal in males and the labial in females.

Clinical Relevance: Neural compression by space-occupying lesions, enlarged vessels, or overgrown connective tissue in the inguinal region can cause pain or tingling in the groin. External compression by tight clothing can produce similar symptoms. For example, restrictive garments compressing the genitofemoral nerve against the inguinal ligament entraps the nerve, leading to pain and/or numbness on the anterior thigh immediately below the midsection of the ligament.

Obturator hernia, a rare type of abdominal hernia also known as "little old lady's hernia", entraps the obturator nerve with pain and/or tingling and/or paresthesias along the medial thigh, down to the knee. Alternately, the patient with obturator hernia may present with vague symptoms suggestive of bowel obstruction, as when a loop of small intestine becomes lodged within the obturator canal. Patients with this condition may report a dull, cramping abdominal pain accompanied by nausea, and vomiting.[2]

Sites of compression for the anterior division of the obturator nerve occur between pectineus and obturator externus muscles as well as between the adductor longus and brevis. The obturator nerve travels medial to the femoral nerve within the pelvis. Near to where the obturator nerve exits the pelvis through the obturator foramen, it divides into anterior and posterior branches. The anterior branch courses cranial to the obturator externus muscle while the posterior branch courses through it. The anterior division supplies motor innervation to the adductor longus, adductor brevis, pectineus, and gracilis muscles. It also sends sensory supply to the hip joint and medial thigh. The posterior branch supplies the adductor brevis, the adductor magnus, and the obturator externus. It provides sensation to the knee joint as well. Causes of obturator neuropathy include pelvic and acetabular fractures, post-traumatic hematoma, pelvic tumors, obturator hernia, myositis ossificans, penetrating or surgical trauma, and nerve compression by fibrous brands secondary to chronic adductor tendinopathy with osteitis pubis, more common in athletes.

Iatrogenic procedures in the groin, along with blunt or penetrating trauma, may damage the genitofemoral and ilioinguinal nerves, producing persistent pain and paresthesias in the inguinal region.[3] Hyperextension of the hip and physical activity typically worsen the pain from genitofemoral neuropathy, which may extend to the genitalia and proximomedial thigh over LR 10, LR 11, and LR 12.

Damage to the ilioinguinal nerve has been called an "infamous complication of inguinal hernia surgery".[4] Chronic pain syndromes that take hold following iliohypogastric or ilioinguinal nerve injury during open inguinal hernia repair or gynecologic surgery may respond to neuromodulation.

The variability in spinal nerve origin for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy. Conversely, issues related to pain or dysfunction of somatic or visceral tissues served by the T12-L2 spinal segments may benefit from neuromodulation applied to ST 29, KI 12, and CV 3.

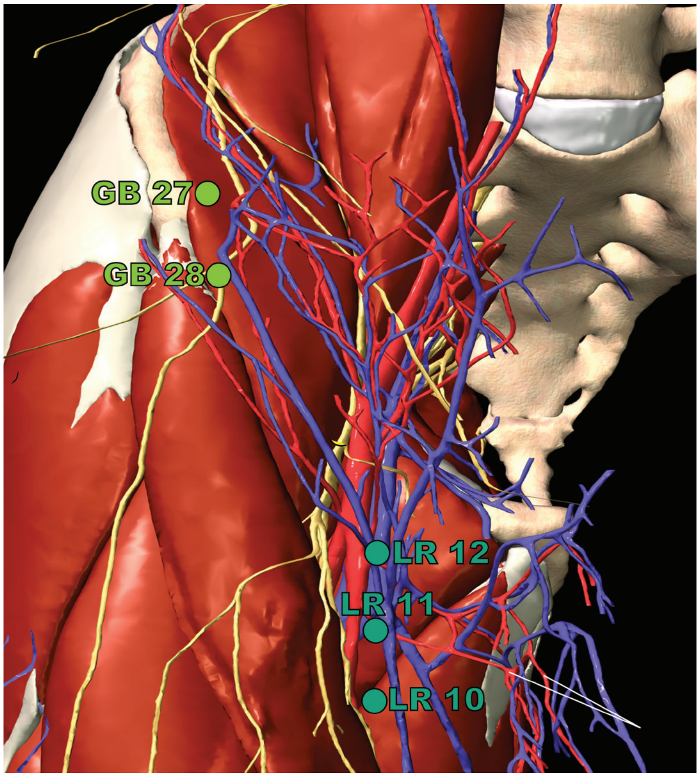

Figure 12-32. This view of the groin-region LR points illustrates the ways in which treatment at each point, i.e., LR 10, LR 11, and LR 12, might impact the pectineus muscle.

Vessels

- **Femoral artery:** Supplies the anteromedial surface of the thigh as well as the anterior surface.
- **Femoral vein:** The femoral vein arises from the popliteal vein.
- **Medial circumflex femoral artery:** Supplies the majority of blood to the femoral head and neck.
- **Medial circumflex femoral vein:** Accompanies the medial circumflex femoral artery and terminates in either the femoral or deep femoral vein.

Clinical Relevance: Obturator neuropathy, i.e., focal obturator nerve entrapment, can be caused by both fascial and vascular compression.

In some individuals, the medial circumflex femoral artery and vein cross the caudal (or posterior) division of the obturator nerve as the latter descends within a fascial plane superficial to the obturator externus and proximal portion of the adductor magnus muscle.[5] Arterial anastomoses between the muscular branches of the medial circumflex artery and the anterior branch of the obturator happen here – vascular abnormalities could cause obturator nerve compression. The presence of vessels overlying the nerve as well as its "low visibility" in imaging studies creates difficulties for clinicians attempting obturator nerve blocks.

Fascial expansions such as perivascular condensations around vessels supplying the adductor musculature produce a definitive layer of connective tissue that may entrap the anterior division of the obturator nerve.[6] The vascular pedicle from the medial circumflex femoral artery that leads to the pectineus, adductor longus, and adductor brevis surrounds the obturator nerve as it courses toward the apex of the brevis, thereby diminishing

space further for the nerve.

The femoral artery and vein enter the adductor canal close to LR 10, at the apex of the femoral triangle. The femoral triangle, bounded superiorly by the inguinal ligament (not shown here), medially by the adductor longus, and laterally by the sartorius, rests upon a floor formed by the iliopsoas muscle and pectineus. The roof of this triangle is built by the fascia lata and cribriform fascia, along with subcutaneous tissue and skin. From lateral to medial, the contents of the femoral triangle include the femoral nerve and branches, the femoral sheath and contents, the femoral artery and branches, and the femoral vein and tributaries (e.g., the great saphenous and deep femoral veins). As such, LR 10 and LR 11 serve as entryways to a high traffic zone replete with vessels and nerves of major importance.

Indications and Potential Point Combinations

- **Genital or pelvic pain:** LR 12; examine for trigger points, taut bands, and other local constrictions that may be compressing peripheral nerves.
- **Postoperative abdominal pain:** Apply pressure to LR 12.[1]
- **Hernia:** LR 12, ST 29, SP 13, GB 27; take care not to puncture intestinal contents involved with the hernia.
- **Thigh pain:** Identify, to the degree possible, whether the pain stems from myofascial dysfunction, nerve entrapment, or both.

LR 12 and LR 11 target the pectineus trigger points, though other points in the area will be required to address other myofascial components and fascial restriction.

LR 13

Zhang Men "Completion Gate", "Camphorwood Gate", "Screen Gate"

"Camphorwood Gate", "Screen Gate" Slightly distal and ventral to the tip of the 11th rib.

Also found where the tip of the patient's elbow touches the lateral thorax.

Muscles

- **External oblique muscle:** Flexes and rotates the trunk; supports and compresses internal organs.
- **Internal oblique muscle:** Flexes and rotates the trunk; supports and compresses internal organs.
- **Transversus abdominis muscle:** Compresses and supports the internal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Referred pain from trigger points in the abdominal oblique and transversus muscles can upset digestion. Or, referred pain may course in across the abdominal wall, extending toward the ipsilateral or even the contralateral subcostal margin, the umbilicus, the groin, and/or the genitalia. Needless to say, this leads to a variety of diagnostic dilemmas.

Enthesopathy where the internal oblique attaches to the costal margin can produce severe pain during coughing. View this attachment site in Figure 12-38.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.
- **10th intercostal nerve:** Supplies the skin in this region.
- **11th intercostal nerve:** Supplies the skin in this region.

Clinical Relevance: Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may ensue.[2] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[3] The nerves become entrapped as they travel a fibrous tunnel or where soft tissues compress them. Scar tissue worsens nerve entrapment.

Acupuncture and related techniques address these problems by releasing tissue tension, improving circulation, and fostering repair.

Front Mu points such as LR 13 (the Spleen Front Mu) and their Back Shu partners such as BL 20 (the Spleen Back Shu) influence viscera through communication between somatic and visceral neurons.

LR 13 resides within the T11 dermatome; the spleen organ derives its sympathetic innervation from T8 to T11 spinal cord segments.[4] As such, T11 provides the overlapping spinal

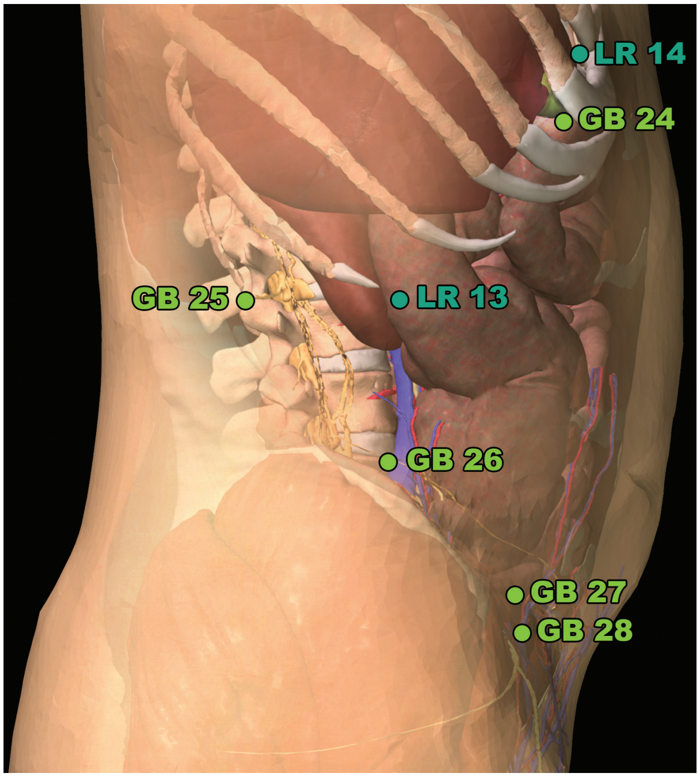

Figure 12-34. LR 13, LR 14, GB 24, and GB 25 all carry special significance as "Front Mu" or "Alarm" points. Tenderness to palpation at a Front Mu or Back Shu point may indicate dysfunction in its associated organ. The related organs for the Front Mu points appearing here are, respectively, spleen, liver, gallbladder, and kidney.

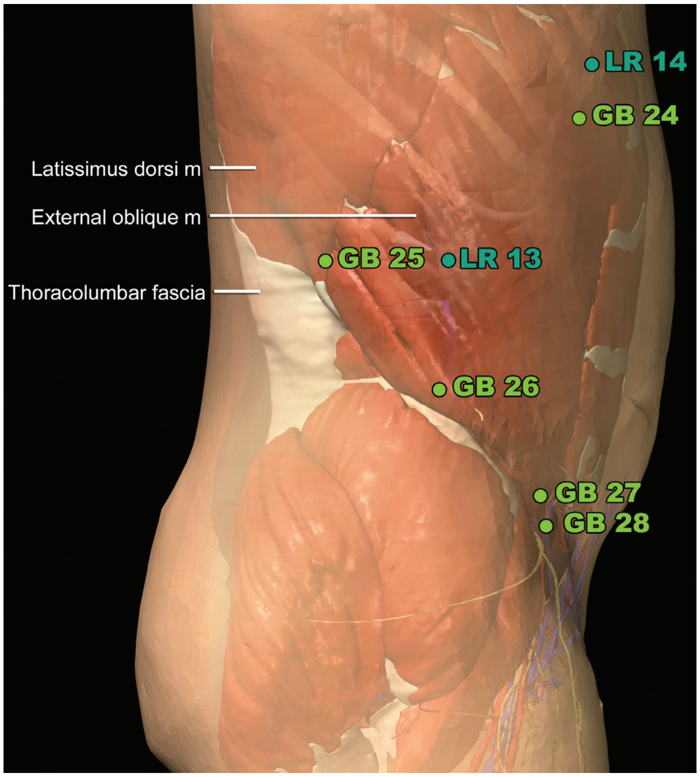

Figure 12-35. Visceral disease may trigger pain in abdominal wall musculature. Thus, tenderness to palpation at LR 13 can reflect internal organ dysfunction or abdominal wall pathology such as nerve entrapment or myofascial strain.

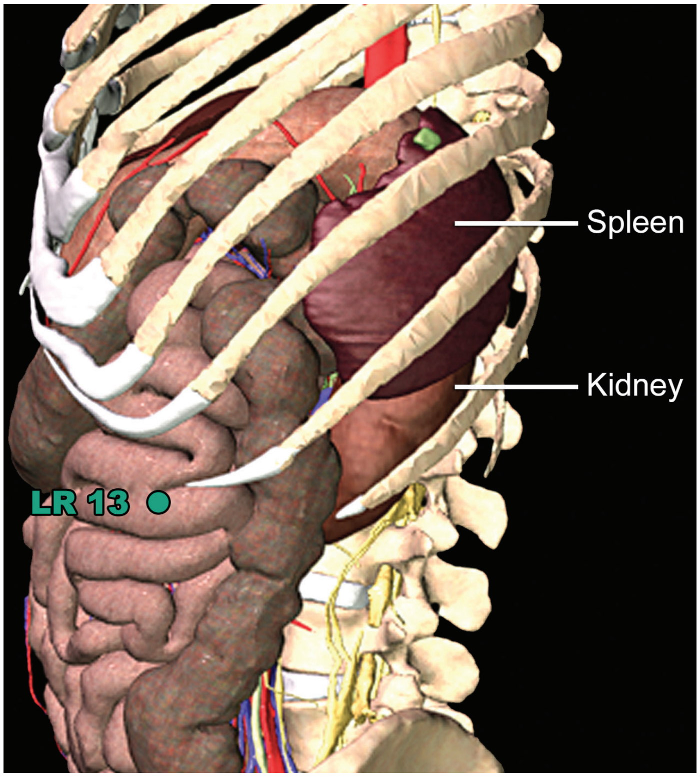

Figure 12-36. This left hemithorax illustrates the relationship between LR 13 and the spleen organ. Both appear along the same intercostal level, implicating spinal segmental overlap. The descriptive term for LR 13, "Screen Gate", connotes the way in which the ribcage resembles a screen. The term "Completion Gate" suggests that LR 13 serves as the gateway to LR 14, where the course of the twelve, paired channels becomes complete.

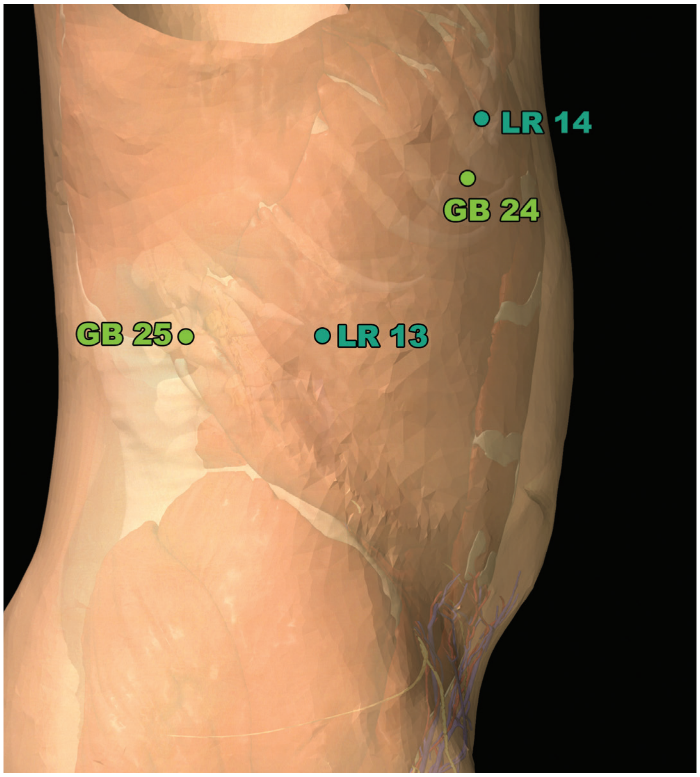

Figure 12-37. GB 25, LR 13, GB 24, and LR 14 fall along a crescent that follows the costal margin.

cord segment between somatic and organ supply. That said, nociceptive input from the body wall travels to several segments of spinal cord, not just one, introducing numerous possibilities for information exchange.

Vessels

- **Anterior and collateral branches of the 11th posterior intercostal arteries:** Supply the skin and muscles of this region.
- **Anterior and collateral branches of the 11th posterior intercostal veins:** Drain the skin and muscles of this region.
- **Anterior branches of the subcostal artery:** Supplies the skin and muscles of this region.
- **Anterior branches of the subcostal vein:** Drain the skin and muscles of this region.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Pain in the lateral thorax:** LR 13, GB 22, GB 25, tender trigger points.
- **Pleuritis:** LR 13, local trigger points as found. LU 1, LU 7, BL 13, BL 23.
- **Low back pain, with a feeling of cold in the low back or abdomen:** LR 13, GB 25, GB 26, GB 41, TH 5, BL 23, BL 52. Add massage and laser therapy; consider heat application.

Evidence-Based Applications

- Electroacupuncture at LR 13, GV 2, and GV 14 encouraged improved **survival of skin flaps** in rats compared to sham points.[1]

Figure 12-38. This cross section illustrates the locus of connection where, in this case, the right internal oblique muscle attaches to the costal cartilage of the twelfth rib. Myofascial pathology here can cause intense pain when the abdomen suddenly and forcefully contracts, as when coughing. The transversus abdominis muscle may serve as an accomplice.

LR 14

Qi Men "Cycle Gate"

In the 6th intercostal space, on the midclavicular line, approximately 4 cun lateral to the anterior midline.

Some authors suggest placing LR 14 in the first full intercostal space palpable above the costal arch, which in this case would displace or coincide with GB 24, as shown in Figure 12-39. Considering that sympathetic fibers from T8-T11[3] supply both the liver and gallbladder, moving both LR 14 and GB 24 one interspace caudad from their traditional locations seems justified neuroanatomically.

Muscles

- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.

Clinical Relevance: Trigger points in the intercostal muscles at LR 14, when the point is treated either in the 6th or 7th intercostal space, incite mainly local pain. Severe myofascial dysfunction may cause pain to travel toward the sternum. Or, patients complain of having a "stitch in the side", although diaphragmatic trigger points may also cause this sensation.

The external intercostal muscles contain more muscle spindles than do the internal intercostal muscles. Intercostal muscles inhabiting the most cranial seven intercostal spaces exhibit a greater density of muscle spindles than do those in the lower thorax. As such, physical medicine interventions in the cranial thorax might deliver a more robust response. At any location over the thorax, however, acupuncture of the intercostal muscles risks causing internal organ damage, illustrated by the cross-section of Figure 12-41. Therefore, acupressure, medical massage, soft tissue manipulation, and laser therapy should substitute for acupuncture for intercostal trigger points. Stretching or yoga may also help, along with corrective deep breathing exercises.

Nerves

- **6th intercostal nerve:** Supplies the skin and muscles of the 6th intercostal space.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin cranial to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin caudal to the umbilicus.

Clinical Relevance: Intercostal neuralgia produces pain of a burning, electrical, or stabbing type.[4,5] Trigger point and general myofascial release may aid in the reduction of neuropathic pain.

Vessels

- **Superficial thoracoepigastric vein:** Provides a collateral pathway by which the femoral vein can communicate with the axillary vein in the event of inferior vena caval obstruction.
- **Anterior intercostal arteries:** Derived from the musculophrenic arteries (branches of the internal thoracic arteries), the 6th and 7th anterior intercostal arteries supply the 6th and 7th intercostal muscles, respectively, along with the pectoral muscles, the breasts, and the skin.
- **Anterior intercostal veins:** Tributaries of the internal thoracic veins and accompany the intercostal arteries to drain venous blood from the 6th and 7th intercostal spaces.

Clinical Relevance: Reduced blood supply from muscle tension and connective tissue fibrosis reduces arterial blood supply and venous and lymphatic drainage.

The venous connection made by the thoracoepigastric vein serves as the vascular basis for the cycle completion between LR 14 and LU 1.

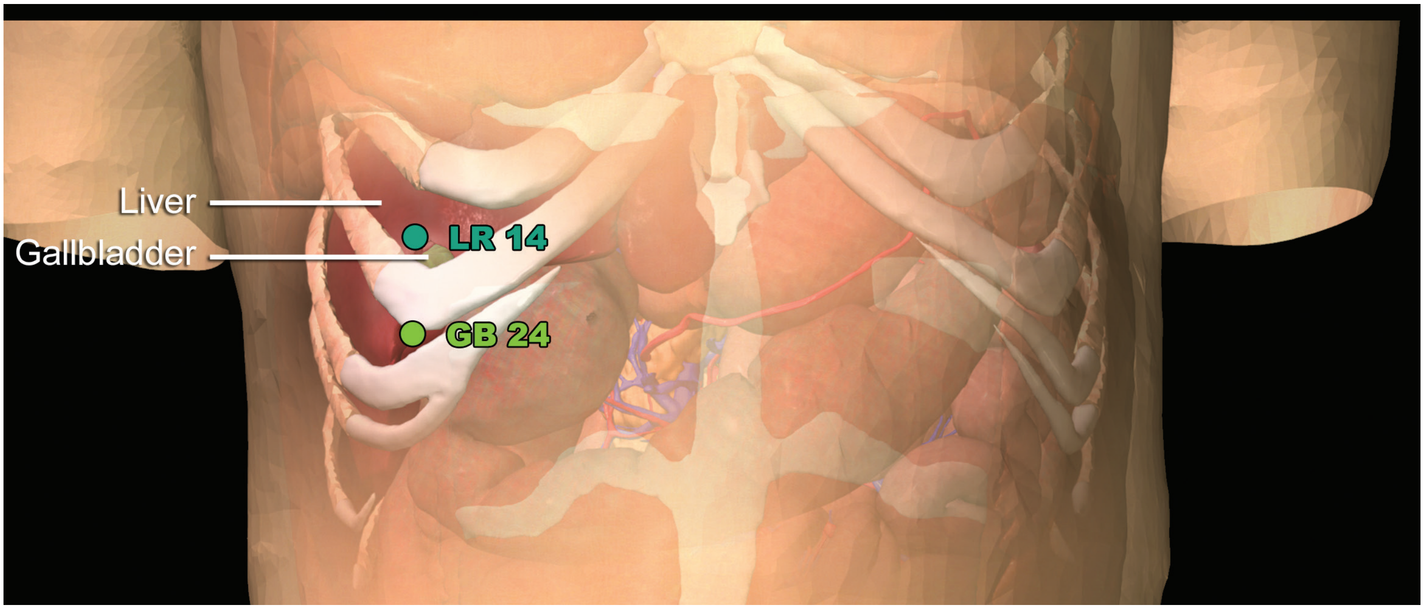

Figure 12-39. At their conventional locations, the right-sided LR 14 and GB 24 land close to the liver and gallbladder. On the left side in either location, they lie superficial to digestive structures; i.e., the stomach and transverse colon, respectively.

Indications and Potential Point Combinations

- **Pain in the chest, diaphragm, or lateral costal region:** LR 14, LR 13, BL 20, BL 21, CV 15.
- **Hepatitis, other hepatobiliary problems:** LR 14, GB 24, BL 18, BL 19, ST 36.
- **Vomiting:** LR 14, PC 6, ST 36.
- **Hiccoughs:** LR 14, CV 22.
- **Intercostal neuralgia:** LR 14, related trigger points.

Evidence-Based Applications

- **Laser acupuncture significantly outperformed sham laser for the treatment of mild to moderate depression with the following points:** LR 8, LR 14, CV 14, CV 15, HT 7, SP 6, LI 4, and GV 20.[1]
- Laser acupuncture at LR 14, CV 14, LR 8, HT 7, and KI 3 provided a statistically and significantly significant benefit in the treatment of **major depression.**[6] These same points increased brain activation in the frontal-limbic-striatal regions in healthy individuals.[7]
- Acupuncture at LR 14, LR 3, CV 6, CV 12, BL 17, BL 18, BL 23, SP 6, and SP 10 may have contributed to resolving **amenorrhea** in an athlete (case report).[8]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6 plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LR 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[2]

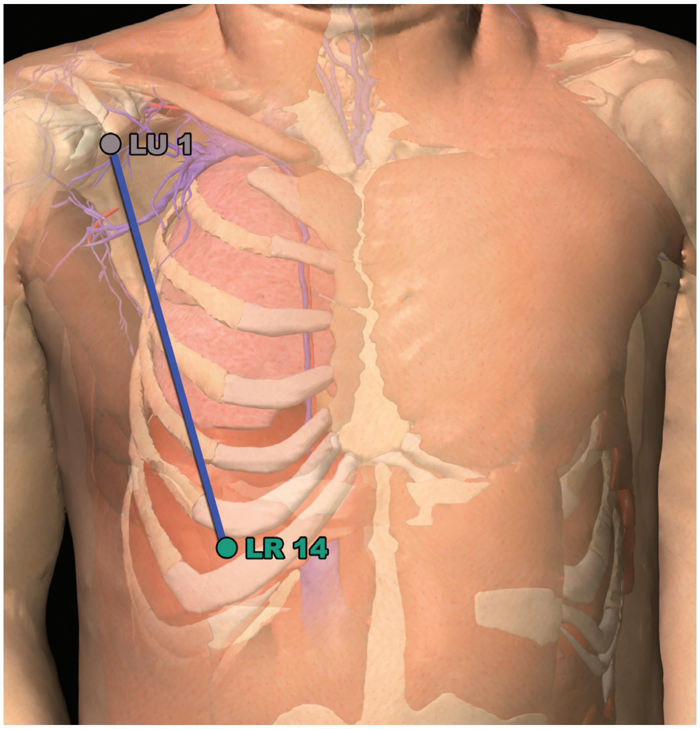

Figure 12-40. LR 14, "Cycle Gate", completes the tour, or cycle, of the twelve paired channels over the ventral, lateral, and dorsal surfaces of the body. The thoracoepigastric vein serves as the "gate" that completes the cycle. When needed, as in the case of inferior vena caval obstruction, the thoracoepigastric vein (represented here as a straight blue line) drains blood from the region around LR 14 to LU 1. The entire collateral communication route spans from the inferior vena cava distal to the obstruction, to the common iliac vein, external iliac vein, femoral vein, superficial epigastric/superficial circumflex iliac veins, thoracoepigastric/lateral thoracic veins, axillary vein, subclavian vein, brachiocephalic vein, and finally back into the superior vena cava.[9]

Section 4::

The Eight “Singular Vessels,” “Extraordinary Vessels,” or “Curious Meridians”

The Eight Singular Vessels

Also called “Extraordinary Channels” and “Curious Meridians”

Singular Vessels – Channels and the Vessels They Represent:

- **Governor Vessel = Venous plexuses of the spine and drainage pathways of the CNS and back**
- **Conception Vessel = Venae Cavae**
- **Chong Mai = Aorta**
- **Dai Mai = Subcostal vessels and sympathetic, thoracolumbar nerves**
- **Yang Wei Mai, Yin Wei Mai, Yang Qiao Mai, and Yin Qiao Mai = superficial venous networks on the pelvic limbs**
- **Yang Wei Mai, Yin Wei Mai, Yang Qiao Mai, and Yin Qiao Mai = superficial venous networks on the pelvic limbs**

Section 3 presented the points and trajectories of the twelve paired acupuncture channels. Now, Section 4 adds the two midline channels. These two belong to a set of eight channels that correspond to singular, or unitary vessel systems. In contrast to the singular vessels, the previously described paired channels comprises a right and left trajectory. Each of the eight singular, vessels demonstrates a uniqueness in some manner, whether unpaired as in the case of the vena cava and aorta, or set apart from its anatomical associates functionally, as in the case of the subcostal veins, arteries, and nerves.

The ventral and dorsal midlines channels, i.e., the Conception Vessel (CV) and Governor Vessel (GV) respectively, begin in the distal pelvis and end near the mouth. CV and GV are the only two from the eight singular channel system that have their own points and pathways. The other six lack linear avenues and classical surface locations assigned to them alone.

While fanciful ideas abound about their true nature, they in fact describe real anatomical entities. Unfortunately, erroneous translations incorporating descriptors such as “marvelous”, “curious”, or “extraordinary” have contributed to notions that these structures ferry spiritual, metaphysical energies through intangible, mystical pathways. Some insist that only the adept acupuncturist should attempt to influence the singular vessels with acupuncture, intimating that their “curious” contents are far too sophisticated and otherworldly for amateurs to engage or manipulate.

The reason that the material basis of these channels has eluded most Western acupuncture practitioners harkens back to translation errors from George Soulié de Morant.[1] Although he came close to recognizing their true nature by calling them “vessels”, Soulié de Morant still clung to hopes that acupuncture worked through unseen energies. Fortunately, Kendall exposed their tangible bases, coining the term “singular distribution vessels” instead of “marvelous meridians”. In his groundbreaking book, *The Dao of Chinese Medicine,* he explained:[2]

> “The singular distribution vessels consist of three major deep vessels of the body, including one arterial vessel and two venous vessels, in addition to five pairs of superficial distribution veins. Called *jimai* in Chinese, these vessels are considered singular because they are not assigned to any particular internal organ. Here, the character *ji* means singular, but is also identical in form to the character *qi*, typically used to mean strange. This character *qi* can also be interpreted as extraordinary, which is commonly contracted to mean extra, resulting in the singular distribution vessels being referred to as the ‘eight extra vessels.’ Being a critical part of the circulatory network, the singular vessels have regulatory functions over particular main distribution (jing) vessels (i.e., the twelve main channels: LU, LI, ST, SP, etc.) Certain nodes (i.e., acupuncture points) on those regulated distribution vessels represent confluent locations (called master and couple nodes) that are applied in the treatment of particular clinical indications.”

Whereas Soulié de Morant likened the eight vessels to canals or drains “for the excess of floods”, Kendall recognized the venous structures as capacitance vessels. To illustrate this disparity, in de Morant’s translation of the *Zhen Jiu Yi Xue”, Easy Studies in Needles and Moxa* by Li Shouxian in 1798, he wrote:

> “The meridians are twelve; the secondary vessels, fifteen. Energy and blood continue their course in them like water in large rivers… But when the rain of the sky is too abundant, all the large rivers suddenly swell and overflow, filling canals and drains. That is what one wishes to express when saying that the illness penetrates and fills the marvellous (sic) vessels. If one treats these conditions using the twelve meridians and there is no response, one must use the master points of the eight marvellous vessels. This causes the so-called canals and drains to circulate.”[3]

In contrast, Kendall brought actual anatomy and physiology into the picture in this translation of a passage from the ancient Nanjing:[4]

> “By analogy, the eight singular vessels are like a plan drawn up by the Sage of irrigation ditches and canals. When these irrigation ditches and canals are filled to overflow capacity, they pour into deep lakes. Therefore, using the Sage’s analogy, when there is an inability to constrain the distribution of blood and vital substances, the vessels in the human body will swell and bulge to excess. Blood then flows into the eight singular vessels so as not to circulate throughout the periphery and therefore relieve the twelve main distribution vessels when they cannot constrain the flow.” (Nanjing, Difficulty 28: the Eight Singular Distribution Vessels)

Kendall provides further insight by approaching the conceptual basis of the eight singular vessel system from a structure-function perspective:[5]

> “The study of therapeutic bloodletting led to early investigation of the vascular system. Much effort went into understanding vessel pathways, branching, and organization. All significant blood vessels of the body were identified, and many are named in relation to the anatomical region they serve, as well as to an associated internal organ. Twelve pairs of matched longitudinal arteries and veins (six pairs on each half of the body) comprise the organ-related main distribution vessels (jingmai). The collateral branches (luomai) of these main vessels supply tissues in the superficial and deep areas of the body. Collateral vessels divide further into fine vessels (sunmai), which comprise arterioles, capillaries, and venules. Fine vessels communicate between the outflowing arteries and

the return flow venous supply, thus ensuring continuous blood circulation. Vessels, along with associated nerves, provide the anatomical means of communication between the internal and external body, a factor that is essential to health, disease processes, and treatment mechanisms.

"Because there are more veins than arteries, the ancient Chinese identified five pairs of superficial venous networks that are not associated with internal organs. These veins, plus two deep major veins, are classified as singular vessels (jimai). About 70% of blood is now known to be in the slow-flowing veins, 11 to 12% is found in the fast-moving systemic arteries, and 5 to 6% is contained in the systemic capillaries. The remainder is in the lungs (8%) and heart (5%). Normally, the volumetric rate of flow in the veins and arteries is equal, even through the veins hold six times more blood than the arteries. The Chinese understood that veins are capacitance vessels, noting that they have additional capacity to control the relative blood volume between the arteries and veins."

By acknowledging and investigating the structure-function relationships between the vascular pathways, associated neural connections, and acupuncture points, one better understands how and why stimulating points creates the physiologic changes the Chinese noted with acupuncture. For example, analyzing the role of the venous network accompanying the brain and spinal cord provides insight and context about ways in which points stimulated on the GV channel help to lower brain and spinal cord temperature and impact the health of the nervous system in order to benefit patients with epilepsy, stroke, back pain, and headaches.

The Three Deep Singular Vessels: GV, CV, and the Chong Mai

The eight singular vessels in acupuncture fall into two groups. Three of the eight relate to three deep, large vessels. Five channels correlate with five superficial structures or networks. The three deep channels include:

1) GV (Du Mai), which represents vertebral and epidural venous networks attached to the azygous system that drains the back,

2) CV (Ren Mai), pertaining to the superior and inferior vena caval system and their tributaries, and

3) Chong Mai, the Penetrating Vessel or Thoroughfare Vessel, which accounts for the aorta. This is the only arterial pathway among the eight singular vessels.

Of the five superficial venous networks, only the **Dai Mai** (Belt Vessel or Girdle Vessel) offers a distinctly traceable trajectory, one that encircles the waist like a sloping belt.

The remaining four superficial venous networks offer less distinct courses comprised of tributaries that ultimately empty into larger passageways.

Yang and Yin in GV and CV

GV and CV form a complementary pair referred to as the "Sea of **Yang**" and the "Sea of **Yin**", respectively. As the "Sea of **Yang**", the venous system of the GV drains the back, spinal cord, and brain. Conversely, the "Sea of **Yin**", i.e., the vena caval system, receives blood from the Yin, or more caudal and ventral portions of the body including the pelvic limbs, pelvis, abdomen, neck, and face.

The actual veins represented by GV and CV meet in several places. The *Li Shi Zhen* referred to CV and GV as "branches from the same source, one in the front of the body and the other in the back. Just as the human body has the Directing [meaning the CV] and Governing Vessels, nature has midnight and midday: these two vessels are separate but also joined."[6] It continues, "The Governing and Directing Vessels may be seen as a closed circuit, one channel with two branches: one part Yang, the other Yin." And, "Indeed, the Governing and Directing Vessels intersect with each other and form as it were two circles which join up in the Interior."

More recently, Herlihy stated, "The vertebral vein system (GV) is a provision of Nature to equalize pressure, to redistribute blood, and in pathologic conditions of either of the two venae cavae (CV), to act as an alternative path for the continuation of the circulation… we must regard the venous system as being composed of five strata, of which the main two are the caval and vertebral systems…I wish to draw special attention to the pool of blood in the vertebral veins…In and out of this plexus blood runs, not unlike the earliest conceptions of an 'ebb and flow'."[7]

Anatomy and Physiology (Structure and Function) of the Veins Comprising the GV (Du Mai)

The GV begins "in front of the lowest part of the perineum and from this area, travels side-by-side up the interior part of the back (azygous and hemiazygous, and the ascending lumbar veins) to enter the node (i.e., acupuncture point) Fengfu (DU 16 (GV 16)), where it connects with the brain."[8]

The veins forming the GV network create a dynamic reflux-regulating system that operates through the epidural and radicular venous interconnections surrounding the spinal cord.[9,10] This network responds to venous pressure changes by adjusting intravascular resistance. For example, the radicular veins alter their diameter in cases of venous "hyperpression", in order to protect the spinal cord from potentially damaging pressure waves. In addition, venous reflux through the radicular veins offers selective cooling of the spinal cord, just as the dural sinuses help to cool the brain, draining excessively warm blood from sensitive neural tissue.[11,12]

Conjoined with the azygous system, the vertebral venous plexus participates as an alternate route of venous return in cases of caval blockade.[13] At times, however, the capacity of the radicular veins to modulate venous pressure may become overwhelmed. In certain circumstances, such as thrombosis in the inferior vena cava (IVC), epidural veins may dilate due to the increased blood flow through the vertebral venous plexus, resulting in neurologic compression or cauda equina syndrome.[14]

Chronic back pain and radiculopathy may also result from

The Metaphorical Attributes and Vascular Relationships of the Governor Vessel

Metaphorical Attributes	Anatomic Correlate
Warms the Lower Burner and the Bladder Harmonizes sexual function Tonifies Kidney *Yang*	The GV channel arises from the various venous plexuses (i.e. the rectal, vesical, prostatic, uterine, and vaginal plexuses) that drain the pelvis and its contents.
Strengthens the back Nourishes the Marrow	A network of intercommunicating veins empties into both the internal iliac veins and internal vertebral venous plexus. The internal vertebral venous plexus courses along the interior of the spinal column and enters the brain.
Strengthens the mind Lifts the *Qi* Nourishes the brain	Where the GV "enters the brain", at GV 16, the internal vertebral venous plexus connects with the occipital sinus, terminating at the confluence of sinuses, which is the dilated caudal extremity of the superior sagittal sinus. The superior sagittal sinus and the GV channel continue in a rostral direction, in line with the mid-sagittal cranial suture.
Extinguishes Interior Wind	Like the GV channel that "descends along the midline of the head to the bridge of the nose", the superior sagittal sinus links to a nasal emissary vein that emerges through the foramen cecum, an opening near the anterior end of the crista galli. This establishes a connection between the intracranial superior sagittal venous sinus and the extracranial veins of the nasal cavity, although it is not always present in an adult.

epidural and radicular venous congestion.[15] The ability of blood flow to reverse through the relatively valveless vertebral venous plexus explains the spread of certain metastatic lesions, such as the dissemination of prostate cancer cells to the spine.[16] Elevated intra-abdominal pressure causes blood draining the prostate to flow into the vertebral veins.[17] With these anatomical correlates in mind, the metaphorical attributes assigned to the GV by TCM texts no longer need remain elusive when instead explained as the vascular conduits and corresponding neural networks they actually are.

See the Table above for more details.

Anatomy and Physiology of the CV (Ren Mai))

The CV channel (vena cava) "starts below the node‡ Zhongji (RN 3) (CV-3) and travels up through the border of the pubic hair to follow along the interior aspect of the abdomen [medial branches of the superior and inferior epigastric veins], past Guanyuan (RN 4) (CV-4) and up to the throat. It then continues up the cheek, following along the face, to enter the eyes (Chengqi, ST 1)". In the ancient work, the *Ling Shu* (Divine Pivot section of the *Huang Di Nei Jing*), Qibo describes the upper extent of the CV as venous tributaries feeding into the superior vena cava (SVC). These include the internal jugular vein draining the brain and a portion of the face, the external jugular vein draining the head and face and the vertebral veins, draining the brain and neck.[18]

Both CV and GV began at the anoperineal region in the pelvis. At their conclusion, they rejoin on the face. The angular vein as an offshoot of CV communicates with the superior ophthalmic vein of GV via the nasofrontal vein, establishing an anastomosis between the anterior facial vein (CV territory) and the cavernous sinus (a GV structure).

The Ren Mai "controls the internal vessels" and supplies reserve blood to the 12 main channels (paired vascular pathways) by means of adjusting resistance in the large venous passageways, or capacitance vessels. Low-pressure baroreceptors in the walls of the great veins and atria (as opposed to high-pressure baroreceptors in the carotid sinus and aortic arch) send messages to the central nervous system, prompting it to modify blood volume distribution and pressure.

As with GV, dispelling the murky metaphors of TCM clarifies the anatomic and physiologic foundations of the CV channel. The Table on the following page compares the metaphorical attributes with their anatomic correlates in detail

Anatomy and Physiology of the Chong Mai (Thoroughfare Vessel)

Chong Mai energy-based descriptions contend that this "marvelous vessel" connects Pre-Heaven and Post-Heaven Qi. It supposedly accomplishes this by connecting the Kidneys (keepers of the Pre-Heaven Qi; i.e., inherited "Jing Qi" or spiritual-energetic gifts conferred by the mother) to the Stomach (bearer of Post-Heaven Qi or the end-products of digestion absorbed as nutrients). Maciocia comes close to acknowledging a vascular foundation for the Chong Mai in his statement that concerning this "Sea of the 12 channels". He states claims that the Chong Mai "branches out in many small capillary-like vessels" and, as the "Sea of Blood", "controls movement of Blood in the Uterus and controls, too, all the Deep Blood Connecting channels".[19] In the end, though, the discussion resorts to the energy-meridian myth.

In reality, the actual vessel responsible for these activities is the aorta, characterized as "always having a pulse beat". Similarly, in the Ling Shu (Divine Pivot), Qibo refers to the pulsation of the posterior tibial artery, a branch of the Chong Mai.[20] The Chong Mai (aorta) ferries oxygenated blood (carrying nutrients, blood

---

‡ The term "node" is Donald E. Kendall's term for acupuncture point.

The Metaphorical Attributes and Vascular Relationships of the Conception Vessel

Metaphorical Attributes	Anatomic Correlate
Nourishes Blood and *Yin* Regulates the uterus Moves *Qi* in the Lower Burner *(Jiao)* and uterus Affects male reproductive system	The inferior vena cava ultimately receives blood from the entire pelvis.
Activates the Triple Heater to control the transportation and penetration of *Qi* throughout the body	On its way to the inferior vena cava via the hepatic veins, blood draining from the viscera first circulates through the portal system, carrying nutrient-laden fluid (or, metaphorically, Nutritional *Qi*) into the liver for its dispersal throughout the body.
Controls Water Passages and the transformation, transportation, and excretion of fluids Strengthens the Kidneys	About one quarter of an individual's total blood volume circulates through the kidneys per minute, which clears waste from the blood and helps regulate fluid and electrolyte balance. Blood leaves the kidney through the renal vein, which drains into the inferior vena cava.
Controls fat tissue and membranes that anchor, connect, and envelop the organs	This function most likely describes the peritoneum, mesentery, and omentum, which performs the jobs to which the TCM description alludes. The inferior and superior mesenteric veins and their tributaries accomplish the mission of draining these structures.
Regulates the life cycle	Hypothalamic-pituitary-adrenal axis
Promotes the descending of Lung *Qi*	The superior vena cava receives blood from structures cranial to the diaphragm. Blocking superior vena cava blood flow results in a medical emergency known as superior vena cava syndrome (SVCS), which increases venous pressures in the head, neck, thoracic limbs, and cranial thorax, a notable obstruction to the descent of metaphorical *Qi*.

products, immune cells, dissolved gases, neurohormonal and humoral substances, etc.) from the left ventricle through the vessels and organs associated with the twelve main channels.

The "Sea of Blood" or Chong Mai issues branches to the thorax, abdomen, back and pelvic limbs. Its internal pathway extends to the perineum at CV 1. Its abdominal branches migrate to the surface, its head and spinal branches supply the nervous system, and its descending offshoots accompany the Kidney and Liver channels to the foot.[21]

Anatomy and Physiology of the Dai Mai (Belt Vessel)

The Dai Mai, the only horizontal acupuncture channel, corresponds to subcostal arteries and veins as well as nerves that supply sensation and sympathetic support to the mid-truncal, gluteal, and genital regions. The subcostal veins originate from the Du Mai (GV)'s ascending lumbar veins. The Dai Mai's circumferential nature brings it into contact with portions of the paired channels that cross the waist or belt territory. One point on the Gallbladder channel, GB 26, bears the same name ("Dai Mai") as this channel because of its coincidence along the Dai Mai singular vessel.

The functions of both the Dai Mai point (i.e., GB 26) and the Dai Mai singular vessel, or channel, overlap in their structure-function connections. That is, both impact thoracoabdominal nerves, the iliohypogastric nerve, the ilioinguinal nerve, the subcostal (12th intercostal) nerve, and affiliated vessels.

TCM texts assert that the Dai Mai channel harmonizes digestive activities, promotes communication and circulation between the upper and lower halves of the body, and resolves dampness in the lower burner (lower Jiao) or pelvis. A medical acupuncture interpretation translates these activities into physiologic responses culminating from neuromodulation of sympathetic supply to the pelvis from T12/L1. That is, tissues in the Dai Mai region are supplied by subcostal neurovascular structures that influence digestion in the lower intestinal tract as well as circulation to pelvic organs.

The Remaining Four Superficial Singular Vessels

The Yang Wei Mai (Yang Linking Vessel), the Yin Wei Mai (Yin Linking Vessel), the Yang Qiao Mai (Yang Heel Vessel) and the Yin Qiao Mai (Yin Heel Vessel) constitute the four remaining superficial singular vessels. In reality, these pathways consist of long, interlacing venous channels from pelvic limbs to the head.

One might ask why none of the singular vessels extends to the thoracic limbs. The answer can be found in the fact that the venous networks of the pelvic limbs possess different vasodilator characteristics than the thoracic limbs. Humans' upright posture and bipedal locomotion pose hemodynamic challenges; i.e., standing encourages blood to sink to the feet. The hydrostatic pressure gradient induced by gravity raises vascular pressure in the pelvic limbs to about 65 mm Hg higher than in the thoracic limbs.[22] The superficial pelvic limb veins, fed by the four superficial singular vessels, support blood redistribution to other parts of the body in accordance with the moment to moment shifts in regional volume. In this way, the superficial networks may play a capacitance role that assists the larger, deeper capacitance vessels of the pelvic limb.

Summary

Finding the form behind the function of the eight singular vessels releases acupuncturists from relying on myth and belief systems to explain their course and function. The following two chapters delve into the anatomic detail concerning points of the CV and GV venous routes.

Channel 13:: The Conception Vessel (CV)

The Conception Vessel traverses the ventral midline from perineum to chin. Its central location provides neuromodulatory access to nerve fibers from the right and left sides of the body. The singular vessel it represents comprises the deep and inaccessible venae cavae.[1]

Anus

This view of the perineum shows how CV 1 lands within a needle's reach of several key nerves and vessels pertaining to genitourinary activity and anal retention. This image also illustrates the proximity of the prostate to CV 1. Surgery of the prostate may cause iatrogenic damage to nerves supplying the trigone, striated sphincter, bladder neck, and caudal urethra. Such injury risks inducing urinary incontinence. Should this occur, neuromodulation at CV 1 may lessens the symptoms of voiding dysfunction. In women, pelvic organ prolapse and stress incontinence may arise from myofascial dysfunction of the pelvic floor (also called the pelvic diaphragm). Acupuncture and related techniques applied to CV 1 may stimulate recovery of proper pelvic diaphragm biomechanics.

Anus

This view of the perineum provides a window into the pelvis. It exhibits the ventral rami of the sacral nerves as they exit the ventral sacral foramina. The pudendal nerve arises from the ventral rami of S2, S3, and S4. Superficial and deep branches of the pudendal nerve supply CV 1. The pudendal nerve divides into inferior rectal nerves, the perineal nerve, and the dorsal nerve of the penis or clitoris. In addition to supplying the external genitalia, the pudendal nerve courses to the urethral and anal sphincters, the scrotum, and both the bulbospongiosus and ischiocavernosus muscles. Contractions of these muscles participate in ejaculation and feelings of orgasm. Pudendal nerve damage after difficult childbirth or extensive bicycling can cause a temporary loss of function or persistent and painful neuralgia. Neuropathic, burning perineal pain may arise from compressed inferior cluneal nerves that course close to the perineum following the departure (branching off) of the posterior femoral cutaneous nerve.

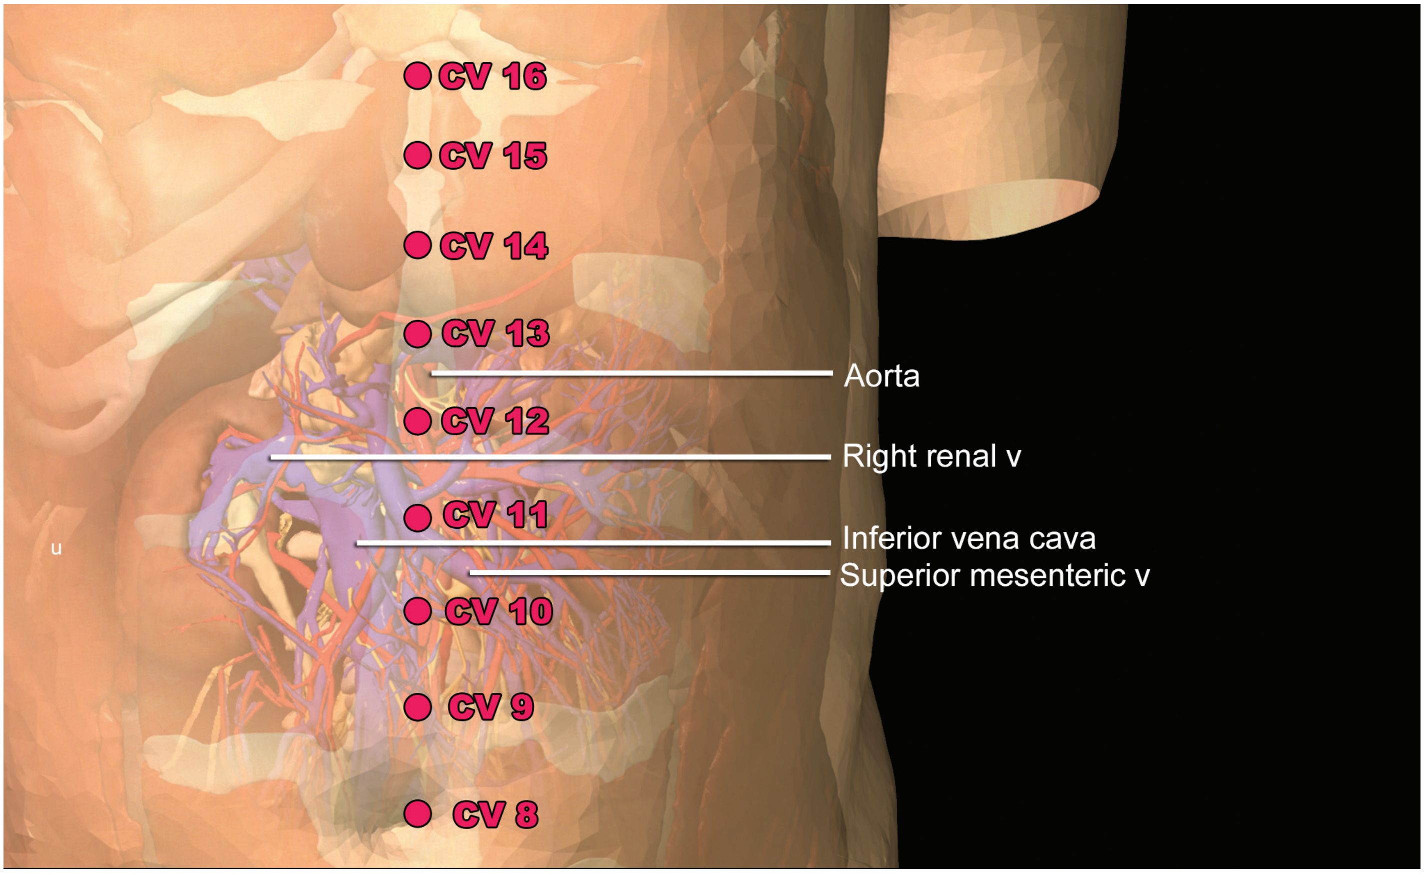
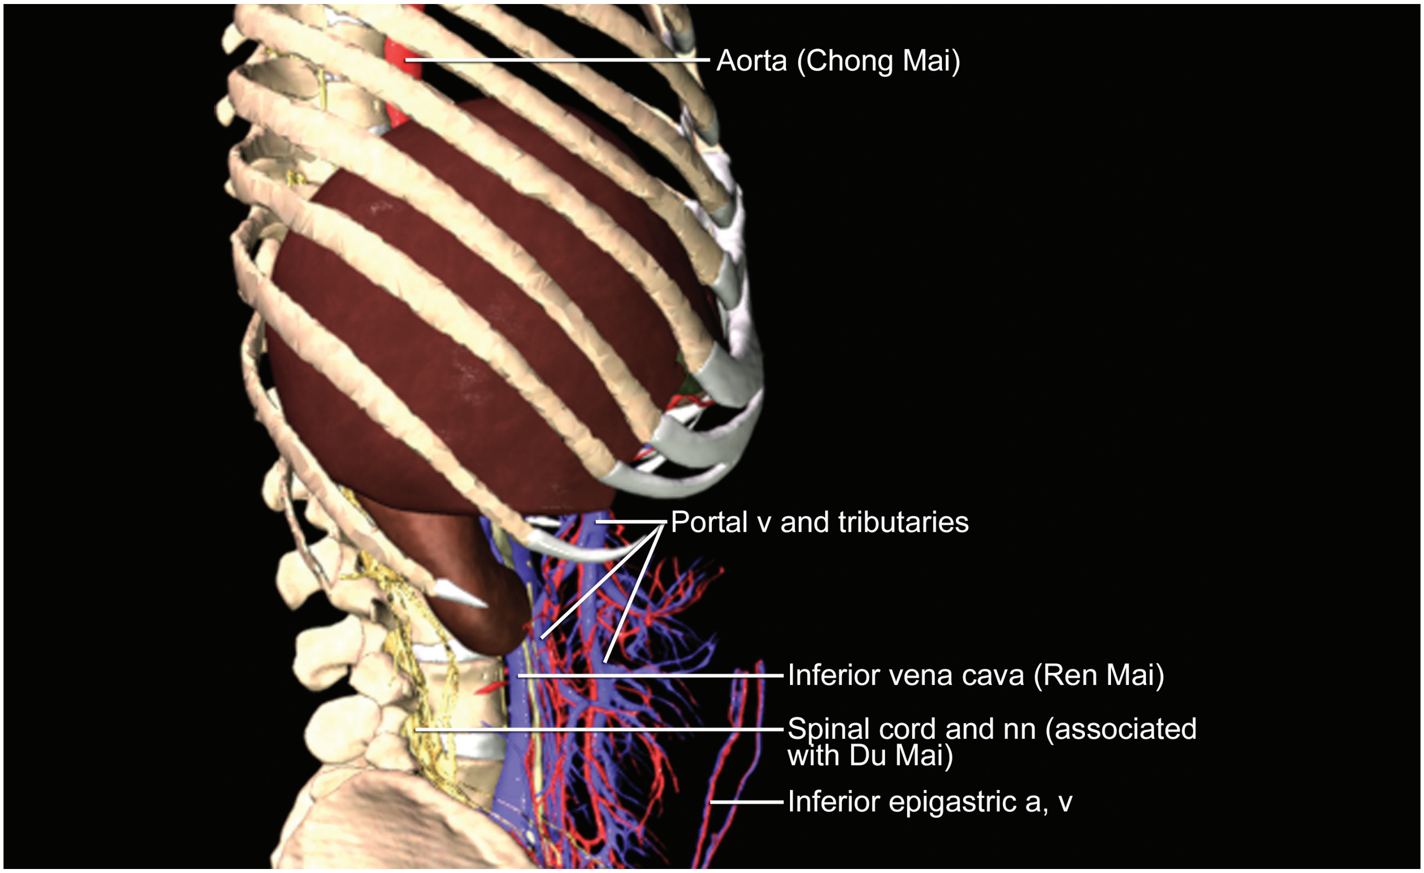
CV ascends the abdomen directly atop the linea alba on the muscle layer and sundry internal organs that deep needling may injure. There is no standard depth at which one places an acupuncture needles. Safe needling depths range from a few millimeters to several centimeters, depending on age, size, and adiposity of individuals.[2]

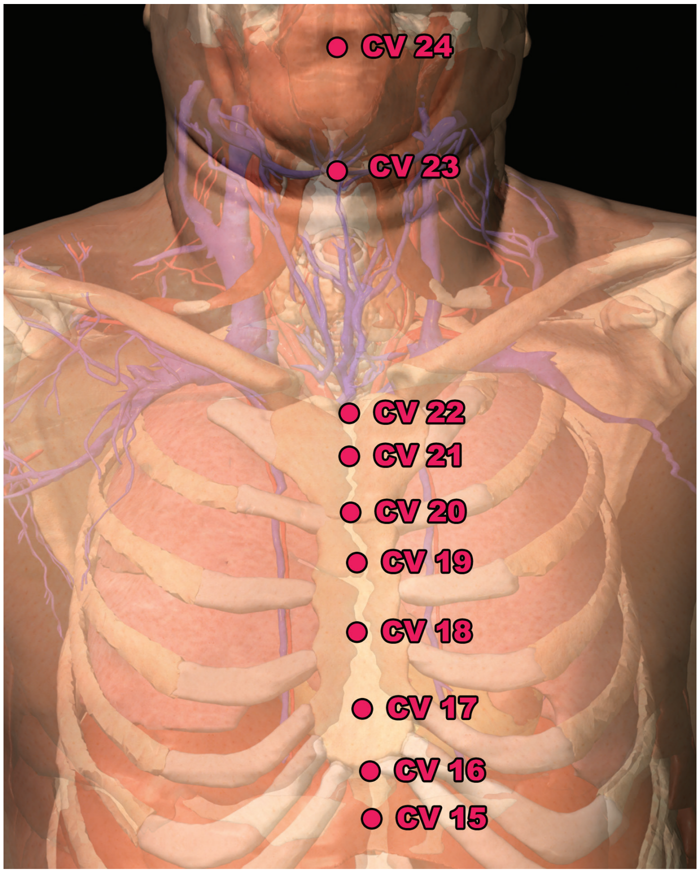


The inferior vena cava (IVC) and hepatic portal vein lie side by side in the abdomen. The hepatic portal vein arises from the confluence of the superior mesenteric vein (labeled in this image) and splenic veins. The portal vein of the liver collects poorly oxygenated and nutrient-dense venous blood from the abdominal gastrointestinal tract that includes the spleen, pancreas, and gallbladder. It empties this blood into the liver for processing. Following filtration and metabolic activities, the liver sends the blood onward and into the IVC via the hepatic veins. In contrast, the IVC, a "systemic" vein. carries deoxygenated blood from the caudal, non-digestive portions of the body into the right atrium of the heart. In cases of portal occlusion, portal hypertension, and cirrhosis, sites of venous juncture between the IVC and portal circulation may become engorged and exhibit varicosities. Varicosities develop in several sites, including the esophagus, rectum, paraumbilical region, and colon. Connections between systemic and portal systems at the esophagus involve the esophageal vein from the azygous (systemic) circulation where it links with the left gastric vein (portal). Hemorrhoids form where rectal veins dilate as the inferior and middle rectal veins (IVC-systemic) intersect with the superior rectal vein on its way to the inferior mesenteric vein (part of the portal venous system). The "caput medusa" develops in the paraumbilical region where anastomosing veins enlarge and radiate away from the umbilicus (CV 8) as the ligamentum teres (the obliterated umbilical vein) and median umbilical ligament join the superficial, superior, and inferior epigastric system (systemic). Finally, venous twigs draining the colon (portal) mingle with systemic retroperitoneal veins. Acquired obstruction of the IVC from cancer or thrombosis prompts the opening of one or more collateral venous circulation pathways. Four major routes offer alternative avenues through which blood from the pelvic limbs and pelvis returns to the heart. A deep pathway leads through the ascending lumbar veins and azygous system, including the intravertebral, paraspinal, and extravertebral plexuses. Another pathway takes blood through the periuretic plexus and left gonadal vein to the left renal vein, with the left side predominating because blood fails to flow as fluidly through the right side. The right gonadal vein empties into the infrarenal IVC which might be blocked by a thrombus. One superficial collateral route connects the external iliac veins with the superior epigastric and internal mammary veins. Blood drains into the subclavian veins and finally the superior vena cava. Another superficial path brings blood from the circumflex iliac veins to the superficial epigastric veins, anastomosing with the lateral thoracic veins and axillary veins through the thoracoepigastric vessels. Finally, venous blood from the pelvic limbs may take a retrograde course through the internal iliac veins and into the hemorrhoidal plexus. From there, it ascends into the inferior mesenteric vein, the splenic vein, and into the portal vein.[3]

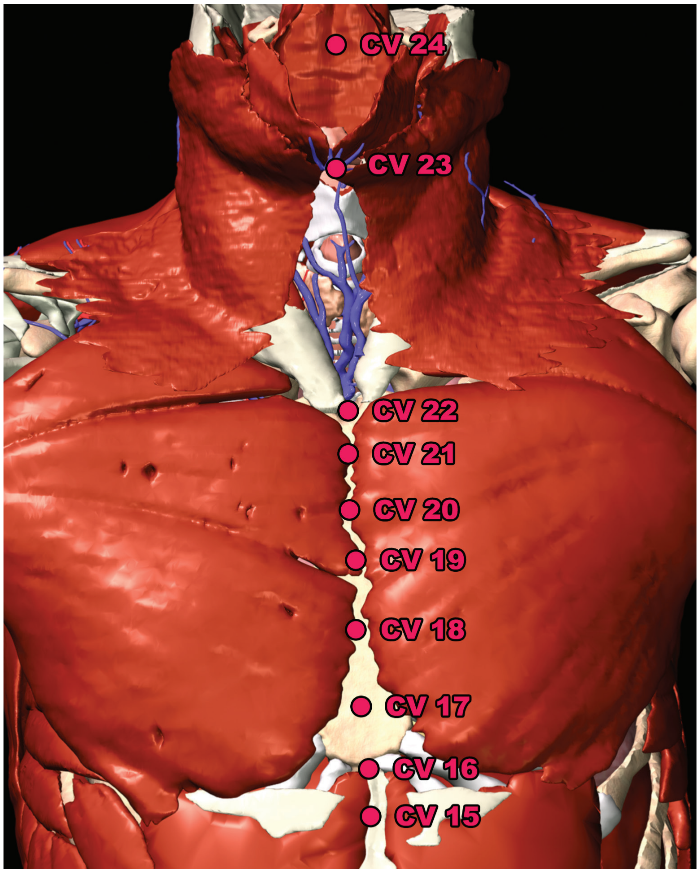


Aorta (Chong Mai)
Portal v and tributaries
Inferior vena cava (Ren Mai)
Spinal cord and nn (associated with Du Mai)
Inferior epigastric a, v

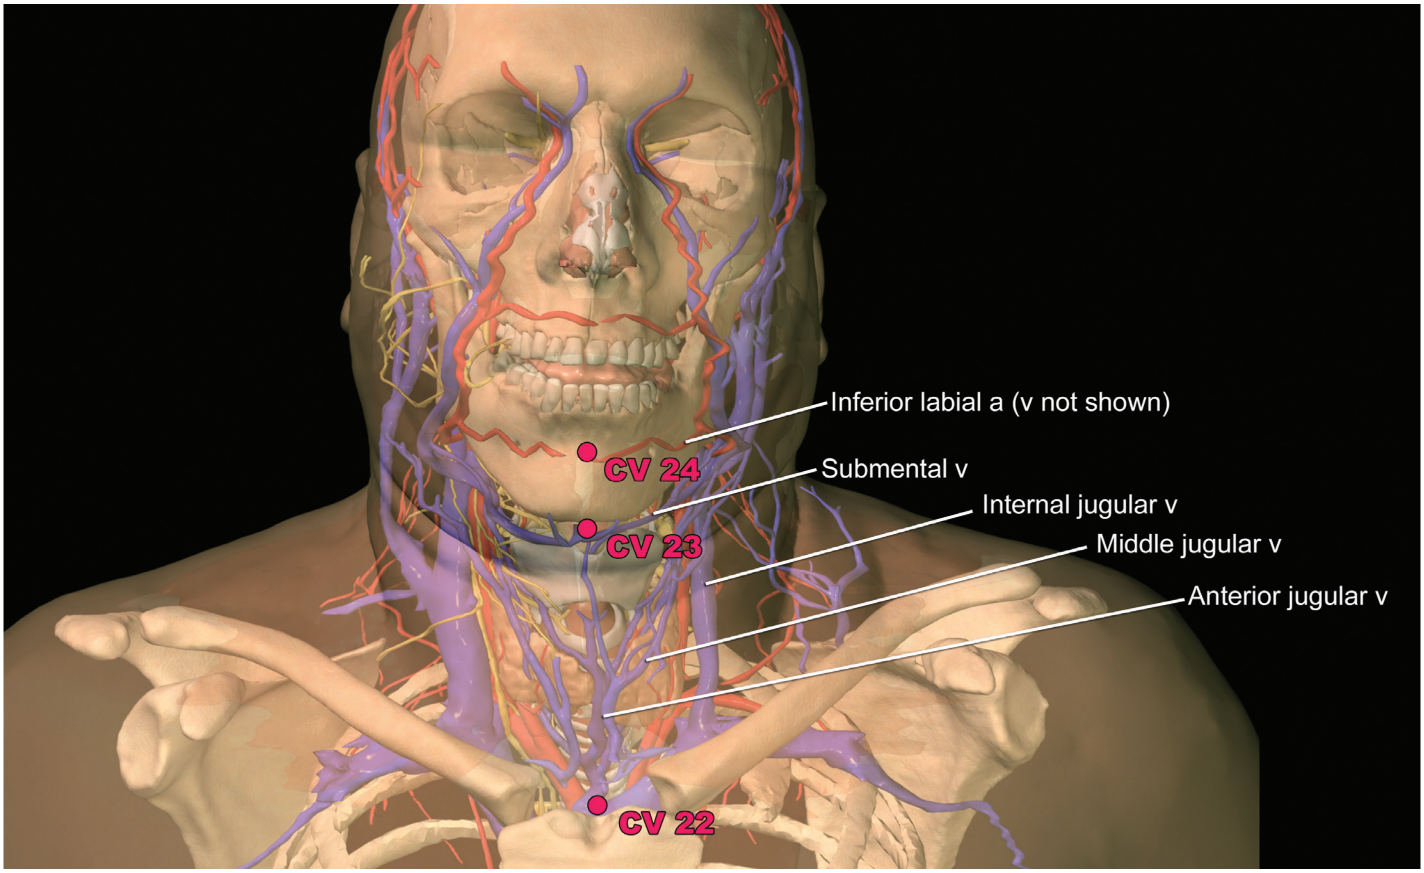
The IVC travels next to the spine and anastomoses with the azygous venous system and epidural venous plexuses. As such, CV and GV, or the caval and azygous/epidural venous systems respectively, communicate and allow blood to redirect its course back to the heart if the usual avenues are blocked. When caval obstruction occurs, due to acquired or congenital (anomalous) blockade, the azygous system then must accommodate the massive blood volume that the IVC would ordinarily have accomodated. This additional avenue of collateral circulation comprises the retroperitoneal and vertebral plexuses, the ascending lumbar veins, and the paravertebral veins which then drain into the azygous and hemiazygous system. On occasion, the testicular and ovarian veins participate in providing parallel pathways.[4] This image illustrates the aorta (Chong Mai), vena cava (CV), and spinal nerves that relate indirectly to the epidural venous plexus (GV).



Veins traversing the anterior chest and abdominal wall contain valves that impel blood toward the midline and the anastomotic venous network interlacing over the sternum.[5] From CV 15 to CV 22, the suprasternal venous network adjoins with the internal thoracic (formerly, mammary) veins and, through those conduits, the brachiocephalic veins.



Pectoral fascia overlying the sternum connects the right and left pectoralis major muscles. This view illustrates the way in which septae of the pectoralis major muscle insert onto the sternum. From a functional perspective, separation of the muscle fibers into individual insertions sets the stage for zonal activation of certain septae. In other words, depending on the movement required, differential activation of portions of the muscle allows for finer motor control along with more precise movements.[6]



The superior vena cava receives venous drainage from the face and neck by means of the internal and external jugular veins. The CV channel ends below the lip at the inferior labial vein (only the artery appears in this image).

CV 1

Hui Yin "Meeting of Yin"

In the center of the perineum, midway between the anus and the caudal border of the scrotum in males, or between the anus and the caudal labial commissure in females.

Caution: Deep needling at CV 1 may injure portions of the penis in males.

Fascial Entity

- **Perineal body:** A pyramid-shaped, fibromuscular mass that contains collagenous fibers and elastic fibers, nerve endings, and both smooth and skeletal muscle. Provides an attachment site for the perineal muscles, including the bulbospongiosus muscle, the external anal sphincter, and the superficial and deep transverse perineal muscles. The rectum also attaches to the perineal body, as do vaginal slips from the pubococcygeus and the anal sphincter.

Clinical Relevance: The perineal body is a vital component of the pelvic floor.[1] Weakening of the perineal body predisposes women to rectocele and enterocele.

Muscles

- **Bulbospongiosus muscle:** Supports the perineal body. In males, it assists erection by compressing outflow veins and pushing blood into the penis. It also compresses the bulb of the penis after ejaculation to expel the final drops of urine or semen. In females, it supplies the sphincter of the vagina and assists in clitoral erection.
- **Superficial and deep transverse perineal muscles:** Help support the abdominopelvic organs and assist them in resisting increased intra-abdominal pressure. Supports the perineal body or pelvic floor.

Clinical Relevance: In women, pelvic organ prolapse and stress incontinence may result from myofascial dysfunction and weakness of the pelvic floor (also called the pelvic diaphragm). Acupuncture and related techniques applied to CV 1 along with appropriate exercises may improve pelvic diaphragm biomechanics.

In men, contraction of the bulbospongiosus and ischiocavernosus muscles contributes to ejaculation and sensations associated with orgasm.

Nerves

- **Perineal nerve:** A branch of the pudendal nerve. Supplies the bulbospongiosus, ischiocavernosus, superficial and deep transverse perineal muscles, and the external urethral sphincter muscles.
- **Pudendal nerve (S2-S4):** The main nerve of the perineum, the pudendal nerve supplies its skin and muscles; as such, it supplies sensation to the lower vagina, vulva, and perineum as well as motor innervation to the perineal muscles. It is also the main sensory nerve of the external genitalia in males.

Parasympathetic and sympathetic nerve fibers proceed to the

Figure 13-2. CV 1, the "Meeting of Yin", lands at the intersection of the singular vessels, CV, GV, and Chong Mai. At CV 1, conduits associated with these channels involve, for CV, the internal iliac vein; for GV, the vertebral venous plexus, and for Chong Mai, the aorta. Connections to the aorta at CV 1 include the internal iliac, internal pudendal, and inferior rectal arteries. This cross section indicates the position of CV 1 on the perineum, the most "yin" or caudal point on the pelvis and entire trunk.

erectile tissue, glands, and blood vessels of this region, coursing alongside the blood vessels and pudendal nerve branches on their way to the perineum.

- **Genitofemoral nerve (L1,L2):** Supplies motor innervation to the cremaster muscle as well as sensation to the posterolateral scrotum in the male or posterolateral labia majora in the female.
- **Perineal ramus or medial inferior cluneal branch of the posterior femoral cutaneous nerve (S1-S3):**[3] Provides cutaneous sensation to the proximal medial thigh. Communicates with the caudal anal nerves and dorsal scrotal nerves.

Clinical Relevance: Superficial and deep branches of the pudendal nerve supply CV 1. The pudendal nerve divides into inferior rectal nerves, the perineal nerve, and the dorsal nerve of the penis or clitoris. In addition to supplying the external genitalia, the pudendal nerve innervates the urethral and anal sphincters, the scrotum, along with the bulbospongiosus and ischiocavernosus muscles. These muscles contract during ejaculation/orgasm. Pudendal nerve damage after difficult childbirth, reconstructive surgery or extended bicycling (e.g., spin class)[11] can cause a temporary loss of function or persistent and painful neuralgia. Pudendal neuropathy produces a sensation of heaviness or burning along the route it traverses. It may cause the patient to feels as though the vagina or rectum contains foreign bodies; sitting worsens the condition.[2]

Neuropathy of the perineal ramus or medial inferior cluneal branch of the posterior femoral cutaneous nerve causes a burning type of perineal pain of the scrotum or labiae majorae, lateral aspect of the anal margin, caudal portion of the buttock, and proximodorsal portions of the thigh. Clunalgia worsens when sitting on a hard surface when the nerve becomes compressed between the ischial bone and the hamstring group of muscles. In contrast, pudendalgia only involves the perineum (penis, anus, and clitoris) and worsens when a bicycle seat or similar structure compresses soft tissues of the perineum.

Surgery of the prostate may cause iatrogenic damage to nerves supplying the trigone, striated sphincter, bladder neck, and caudal urethra. Urinary incontinence may result; if so, neuromodulation at CV 1 may lessen symptoms of voiding dysfunction.

Vessels

- **Perineal artery:** Distributes to the superficial perineal muscles and the scrotum.
- **Perineal vein:** Drains blood from the external genitalia.

Clinical Relevance: Iatrogenic injury of the perineal vessels may follow procedures such as penile implantation.[12]

Indications and Potential Point Combinations

- **Prostate problems:** CV 1, GV 1, BL 34, SP 6.
- **Uterine prolapse:** CV 1, CV 4, GV 20, BL 32.
- **Hemorrhoids:** CV 1, GV 1, BL 35, BL 54, and BL 57.[4,5]

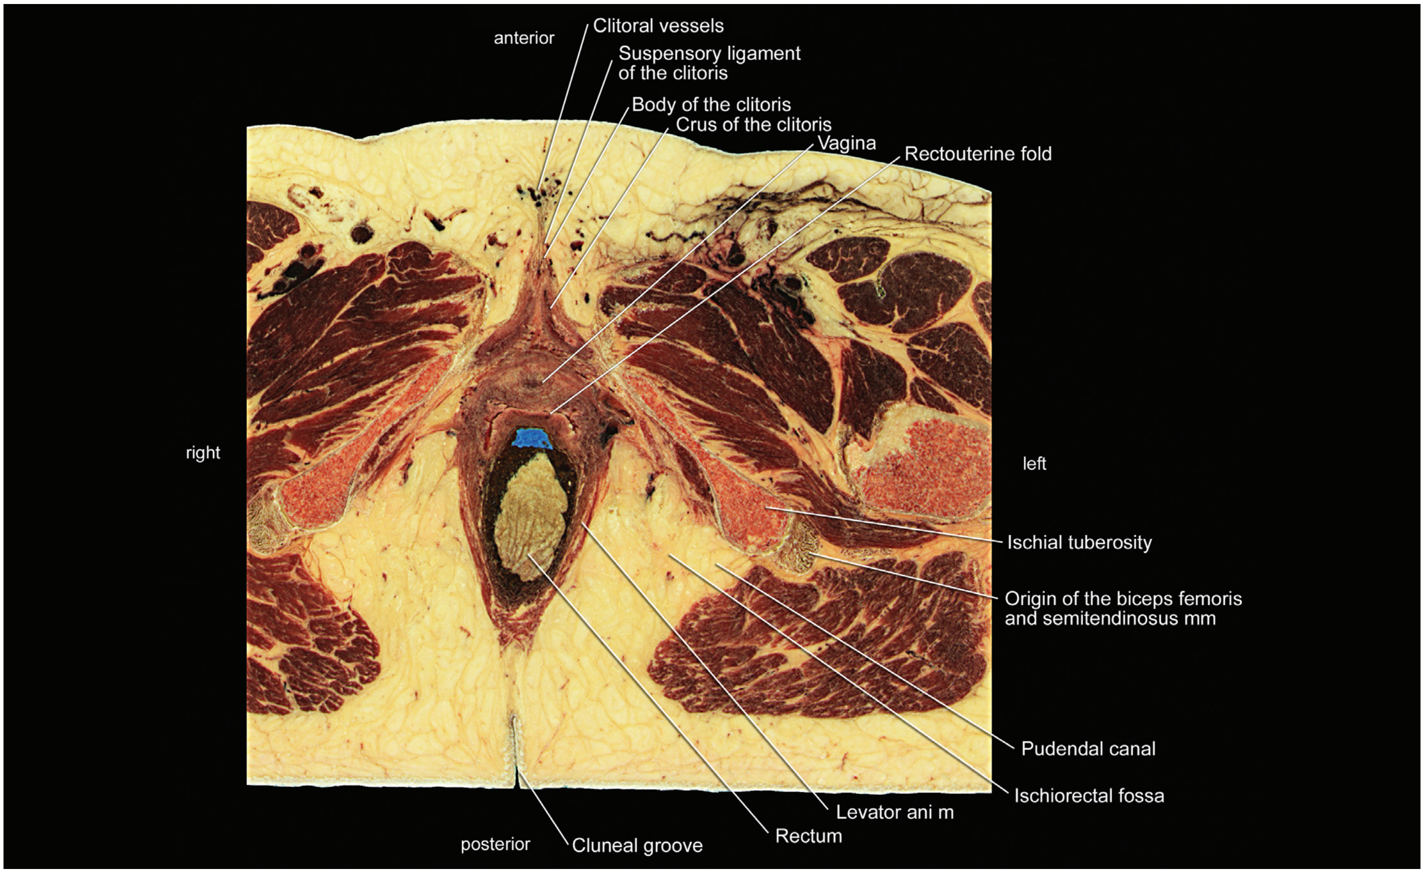

Figure 13-3. CV 1 resides between the rectum and vagina in the female. This cross section depicts the structures located just cranial, or superior, to CV 1.

- **Anal pruritus:** CV 1, GV 1, GV 2, BL 35, BL 57.
- **Scrotal, anal, or penile pain:** CV 1, GV 1, BL 35, BL 36, BL 57. Consider trigger points in the sphincter ani muscle, as they refer a poorly localized, aching pain around the anal region and produce pain upon defecation.
- **Erectile dysfunction due to trigger points in the sphincter ani muscle:** CV 1, GV 1.
- **Dyspareunia during entry in women:** CV 1, GV 1.
- **Genital herpes:** CV 1, LR 9.
- **Enuresis, urinary retention or incontinence:** CV 1, CV 3, CV 4, KI 3, SP 6, BL 23, BL 32.
- **Loss of consciousness:** CV 1, HT 9, GV 20, Yintang.

Evidence-Based Applications

- Neuroanatomically, CV 1 likely benefits **sexual muscle function** by its proximity to the perineal nerve.[6]
- Electroacupuncture at CV 1, CV 2, CV 4, CV 5, BL 21, BL 23, and BL 32 benefited patients with persistent **sensory urgency** after **transurethral resection of the prostate.**[7]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[8]
- Chinese drug injection at CV 1, CV 4, and LR 10 led to improvements in functional and arterial low-level blood supply **erectile dysfunction** in a Chinese research trial.[9]
- Points affecting **ovarian function** in rats with experimentally induced inflammation of the ovary included CV 4, Zigong (EX-CA 1, lateral to SP 13), BL 23, GV 4, GV 1, CV 1, SP 6, ST 36, CV 12, BL 18, and GV 4.[10] Of these, CV 4, Zigong (EX-CA 1), BL 23, and GV 4 delivered the most impact.

CV 2

Qu Gu "Curved Bone"

On the anterior midline, just above the pubic symphysis, 5 cun below the umbilicus.

Fascia

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Median umbilical ligament:** This remnant of the urachus had at one time joined the apex of the fetal bladder to the umbilicus. The median umbilical ligament represents the embryologic remnant of the cloaca and allantois.

Coursing from the urinary bladder to the umbilicus, the median umbilical fold covers the median umbilical ligament.

- **Rectus sheath:** A bilaminar fibrous aponeurotic extension of the three transverse abdominal muscles (external oblique, internal oblique, and transversus abdominis), the rectus sheath encases the rectus abdominis muscle on both sides, from ribs to pelvis. It fuses in the midline to become the linea alba along which the CV channel courses.

Clinical Relevance: Urachal remnant disease, though rare, usually presents in the neonatal period but may cause acute abdominal pain in older children. Differential diagnoses include appendicitis, inflammatory bowel disease, cystitis, strangulated umbilical hernia, abscess, Meckel's diverticulum, and more.[11] Congenital anomalies that impair obliteration of the conduit include persistent urachus, urachal sinus, urachal cyst, and a vesicourachal diverticulum. Signs and symptoms of urachal infection include fever, pain in the lower midline, urinary dysfunction and/or infection, and a palpable suprapubic mass. While acupuncture and related techniques may assist with recovery, patients with an infected urachus likely require surgical excision of the urachal remnant and antibiotics. Do not delay appropriate diagnosis and treatment in favor of trying acupuncture for these patients until medically or surgically indicated measures have been instituted.

Nerves

- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3[12]):** The iliohypogastric nerve divides into anterior and lateral cutaneous branches. The lateral branch supplies the skin over the iliac crest while the ventral branch supplies the skin cranial to the pubic region. Supplies the skin of the hypogastric region and iliac crest. Also supplies the internal oblique and transverse abdominal muscles. The iliohypogastric nerve is the first nerve of the lumbar plexus.[13] The lumbar plexus forms from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or caudal to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.
- **Ilioinguinal nerve (L1, occasionally with T12):** Branches from the ilioinguinal nerve supply the skin of the scrotum and labium majus by means of its anterior scrotal and labial branches, respectively. Other branches supply the skin over the proximal and medial thigh. The ilioinguinal nerve accompanies the spermatic cord or round ligament of the uterus as it moves through the superficial inguinal ring, on the way to its destination of either the scrotum or labium majus, depending on the gender of the individual. The ilioinguinal nerve is involved in the afferent limb of the cremasteric reflex, along with the genitofemoral nerve (L1, L2). Branches of the ilioinguinal nerve include the anterior scrotal in males and the labial in females. Damage to the ilioinguinal nerve has been called an "infamous complication of inguinal hernia surgery".[14]
- **Thoracoabdominal nerves (T7-T12), ventral rami:** In the paravertebral region, the thoracic mixed autonomic, sensory, and motor nerves divide into a large ventral ramus and a smaller dorsal ramus in the paravertebral spaces.

Clinical Relevance: Neuroanatomically, CV 2 supports circulation and neural input to the external genitalia presumably via its association with the iliohypogastric and ilioinguinal nerves from L1.[6] Further, preganglionic sympathetic neurons supplying the reproductive organs arise from the spinal cord segments T11-L2, demonstrating central nervous system overlap of nerve origins.[7] Sympathetic axons from lumbar spinal segments travel to the pelvic plexus by way of the inferior mesenteric plexus and

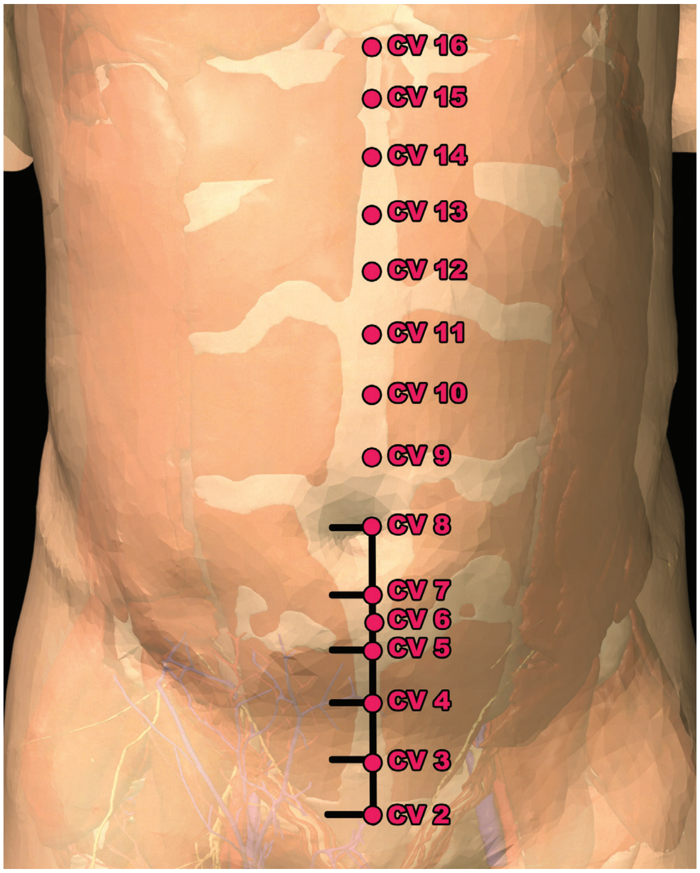

Figure 13-4. One demarcates the location of CV points on the abdomen by means of proportional measurements, as this area lacks distinct topographical features. CV 2, just cranial to the "Curved Bone" or pubic symphysis, begins a line that measures 5 cun to the umbilicus, indicated here.

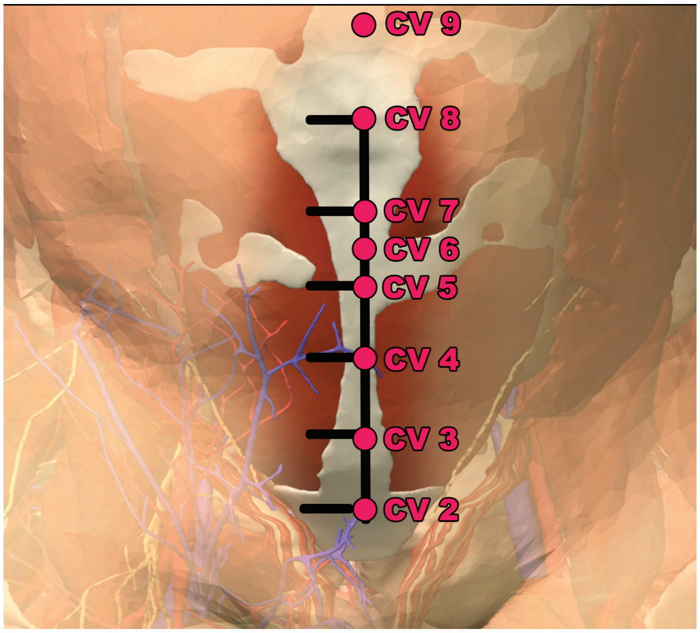

Figure 13-5. The CV line follows the linea alba, shown here as the "white line" beneath the points, from pubis to xiphoid process. This segment, between CV 2 and CV 8, overlies the median urachal ligament, a vestigial remnant of the embryonic urachus.

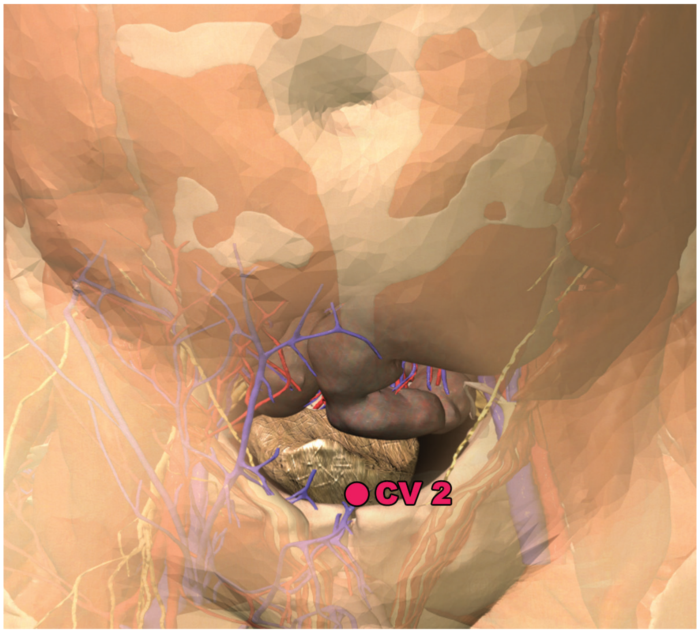

Figure 13-6. Trigger points in the vicinity of CV 2 may provoke symptoms of a urinary tract infection. Conversely, urinary disorders can cause discomfort in the caudal abdomen, from about CV 2 to CV 5. Note the bladder's location deep to CV2, appearing as a fibrous-looking structure, just cranial to the "Curved Bone" (CV 2's descriptive title) of the pelvic rim. Figure 13-7 shows the relationship of the urinary bladder to the pubic symphysis in cross section.

hypogastric nerves. In the pelvic plexus, they synapse on postganglionic sympathetic neurons that project to the genitalia. Axons of preganglionic sympathetic neurons destined for the genitalia originate in lower thoracic spinal cord segments and travel caudad within the sympathetic chain to become postganglionic after synapsing in the S2 through S4 sacral ganglia. Postganglionic axons join the pudendal nerve to supply the genitalia.

Entrapment of the ilioinguinal and iliohypogastric nerves can cause chronic, lower abdominal pain. Injection of local anesthetic relieves the pain, suggesting that acupuncture and related techniques could provide relief as well.

The iliohypogastric nerve communicates extensively with the subcostal and ilioinguinal nerves. The iliohypogastric nerve pierces the transversus abdominis muscle. Some of its branches pierce the aponeurosis of the external oblique muscle. Communication between the genitofemoral and ilioinguinal or iliohypogastric nerves is common, causing overlap of sensory supply. Neurons from T11-L2 travel to the pelvic plexus via the inferior mesenteric plexus and hypogastric nerves.[15] Within the pelvic plexus, synapses take place between the plexus and postganglionic sympathetic fibers that project to the penis. Postganglionic sympathetic fibers consist of two types: cholinergic sympathetic and adrenergic sympathetic neurons. The cholinergic neurons function as vasodilators to the erectile tissue of the penis. Adrenergic neurons activate smooth muscle tissue in the epididymis, vas deferens, seminal vesicles, and prostate gland.

Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis muscle plane, between the internal oblique muscle and the transverse abdominis muscle.[16] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from the plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively. The variability in spinal nerve origins for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy.

Crosstalk among nerves of the abdominal wall impacts anesthetic procedures such as nerve blocks and neuromodulatory approaches, including acupuncture and related techniques. For example, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually neuromodulate several spinal cord segments rather than only one level, thereby extending the treatment's impact more broadly.

Incisions often occur along the linea alba; i.e., the CV line. Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[17] Entrapment of thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[18] Nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction compress their turning points. Entrapment of an anterior branch of a spinal nerve within the rectus abdominis muscle or sheath produces pain in the lower abdomen and pelvis that sometimes simulates gynecologic disease in female patients. In men, entrapped cutaneous abdominal nerves can provoke penile pain. Scars increase the risk of nerve entrapment. Acupuncture may benefit these patients by releasing tension in the tissues and freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[19] Paresis of the abdominal wall can lead to mechanical complaints as well. Considering the benefits of acupuncture and related techniques for peripheral nerve injury, ilioinguinal nerve injury would likely respond to neuromodulation unless the nerves were severed completely. Chronic pain syndromes that take hold following iliohypogastric or ilioinguinal nerve injury during open inguinal hernia repair or gynecologic surgery should also be addressed with neuromodulation, in addition to adjunctive abdominal support and multimodal analgesia.

Vessels

- **Superficial (inferior) epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior (deep) epigastric artery:** Supplies the rectus abdominis muscle and the medial portion of the anterolateral abdominal wall. A branch of the external iliac artery. Anastomoses with the superior epigastric artery within the rectus sheath near the umbilicus.
- **Superficial (inferior) epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior (deep) epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. Collateral venous connections provide alternate routes for venous return from the lower extremities, by bypassing an obstructed or ligated inferior vena cava. Venous blood instead drains into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.
- **Superficial external pudendal artery:** A branch of the femoral artery, the superficial external pudendal artery crosses the spermatic cord and supplies the skin on the lower abdomen, the penis, and scrotum. The superficial external pudendal artery anastomoses with branches of the internal pudendal artery. The deep external pudendal artery also arises from the femoral artery, but in contrast to its superficial counterpart, passes across the pectineus and adductor longus muscles to supply the skin of the scrotum and perineum. The deep external pudendal artery anastomoses with scrotal branches of the perineal artery.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; in more cranial regions, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep surface. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[20] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[21]

The valveless epigastric veins serve as collateral drainage routes for abdominopelvic blood. In the event of vena caval obstruction or ligation., the epigastric veins ferry venous blood craniad across the abdominal wall and into the internal thoracic, subclavian and brachiocephalic veins. From there, it empties into the superior vena cava.

Circulation to CV 2 increased with acupressure to SP 6 in college students with dysmenorrhea.[22] This suggests that tibial and saphenous nerve activation at SP 6 improves blood flow in the pelvis and that both neuromodulation and circulatory changes confer the benefits expected by treatment of SP 6.

Indications and Potential Point Combinations

- **Genitourinary or gynecologic problems:** CV 2, CV 3, CV 4, SP 6, BL 32, BL 34, BL 23 plus others as necessary to address specific neural pathways.
- **Distended abdomen:** CV 2, CV 12, ST 25, ST 36, BL 25.
- **Chronic lower abdominal pain:** Consider abdominal cutaneous nerve entrapment, iatrogenic peripheral nerve injury, or myofascial pain syndrome in addition to intraabdominal pathology.[1]
- **Osteitis pubis:** CV 2, KI 11.[2]
- **Penile pain:** Consider rectus abdominis and puborectalis/pubococcygeus trigger points and target accordingly, including CV 2.[3]

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis**.[4]
- Acupuncture reportedly benefited patients with **urinary retention** in a Chinese clinical trial with the following points: CV 2, CV 3, CV 4, SP 6, SP 9, BL 23, BL 28, BL 32, and BL 39.[5]
- Electroacupuncture at CV 1, CV 2, CV 4, CV 5, BL 21, BL 23, and BL 32 benefited patients with persistent **sensory urgency after transurethral resection of the prostate**.[8]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[9]
- Acupuncture at CV 2, CV 3, EX-CA 1 (lateral to SP 13), ST 25, and ST 28 benefited women with **uterine disorders.**[10]

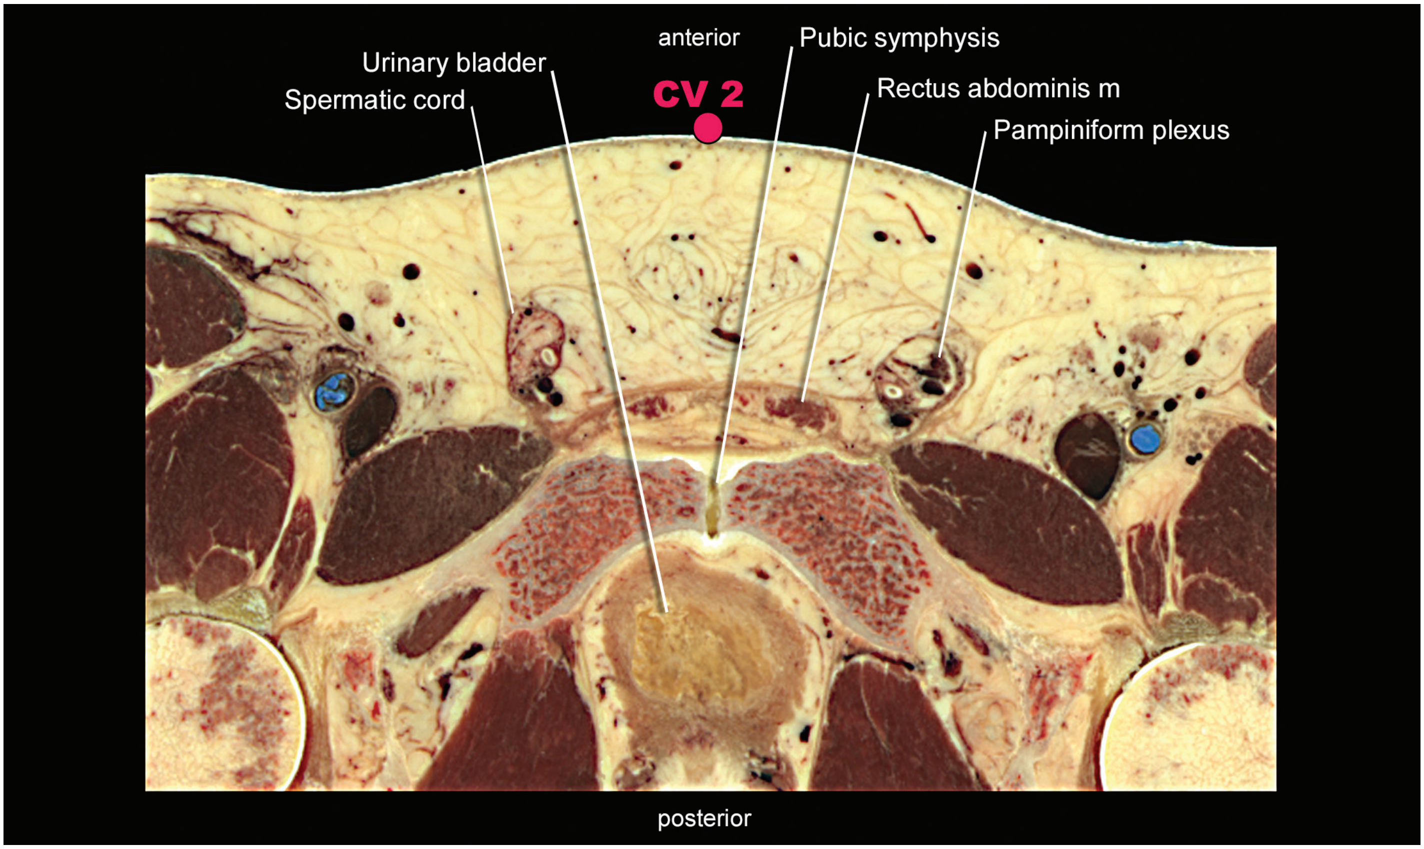

Figure 13-7. (Male pelvis) Somatovisceral and viscerosomatic reflexes can confuse clinical pictures, as trigger points may cause symptoms of genitourinary discomfort, while pelvic organ dysfunction may refer pain to the caudal abdominal wall.

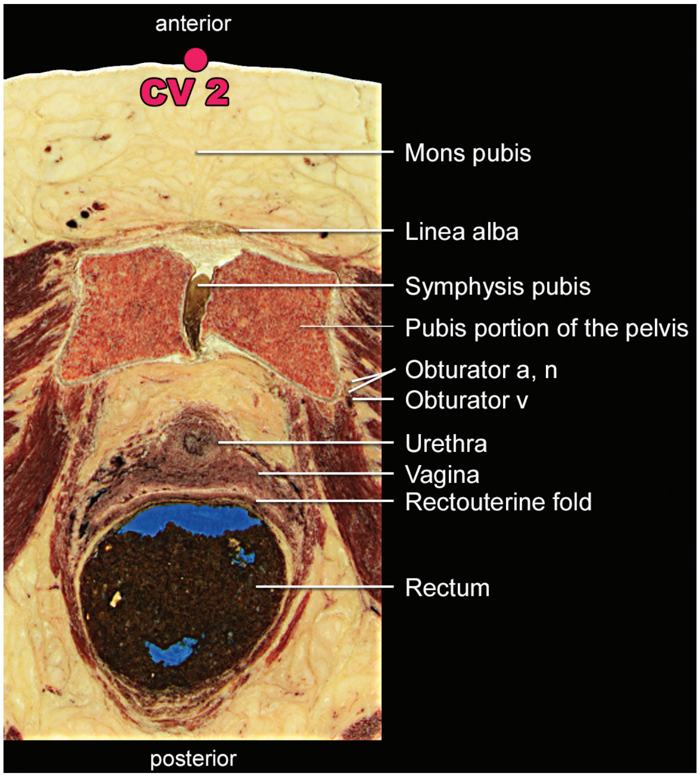

Figure 13-8. (Female pelvis) This cross-section presents contents of the female pelvis deep to CV 2, in contrast to that of the male as shown in Figure 13-7.

CV 3

Zhong Ji "Central Pole", "Urgent Center"

On the midline of the suprapubic region, 1 cun cranial to the cranial border of the symphysis pubis and 4 cun caudal to the umbilicus. In other words, one can find CV 3 1/5 the distance from the pubic bone to the umbilicus.

Fascia

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Median umbilical ligament:** This remnant of the urachus had at one time joined the apex of the fetal bladder to the umbilicus. The median umbilical ligament represents the embryologic remnant of the cloaca and allantois. Coursing from the urinary bladder to the umbilicus, the median umbilical fold covers the median umbilical ligament.

Clinical Relevance: Urachal remnant disease, though rare, usually presents in the neonatal period but may be found in older children suffering from acute abdominal pain. Differential diagnoses include appendicitis, inflammatory bowel disease, cystitis, strangulated umbilical hernia, abscess, Meckel's diverticulum, and more.[13] Congenital anomalies include persistent urachus, urachal sinus, urachal cyst, and a vesicourachal diverticulum. Signs and symptoms of urachal infection include fever, pain in the lower midline, urinary dysfunction and/or infection, and a palpable suprapubic mass. While acupuncture and related techniques may assist with recovery, patients with an infected urachus may require surgical excision of the urachal remnant and antibiotics. Do not delay appropriate diagnosis and treatment in favor of trying acupuncture for these patients until medically or surgically indicated measures have been instituted.

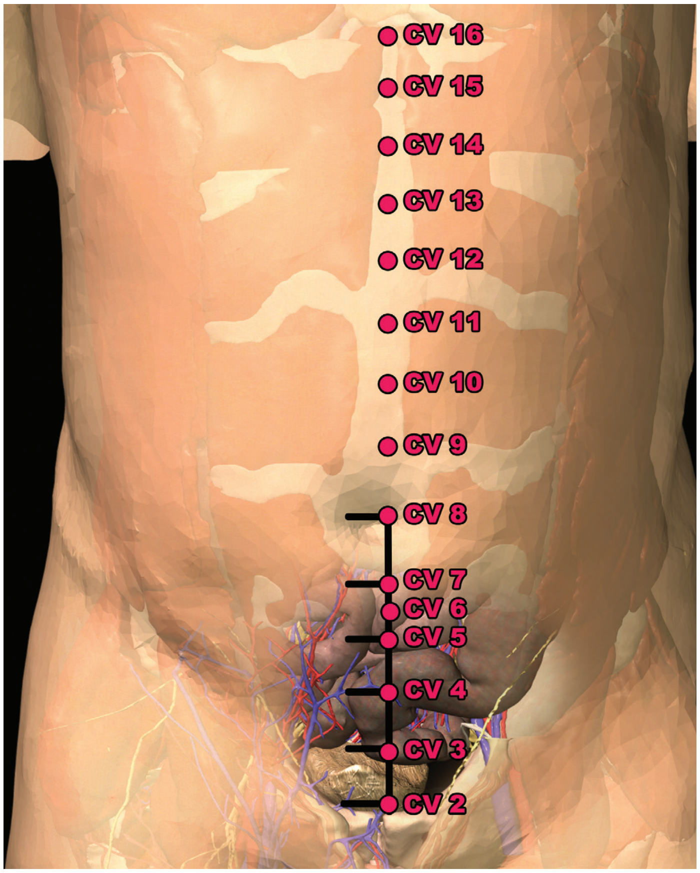

Figure 13-9A. A look inside the abdomen at the level of the caudal abdominal CV points illustrates the relationship between CV 3, the urinary bladder, the sigmoid colon, and pubis.

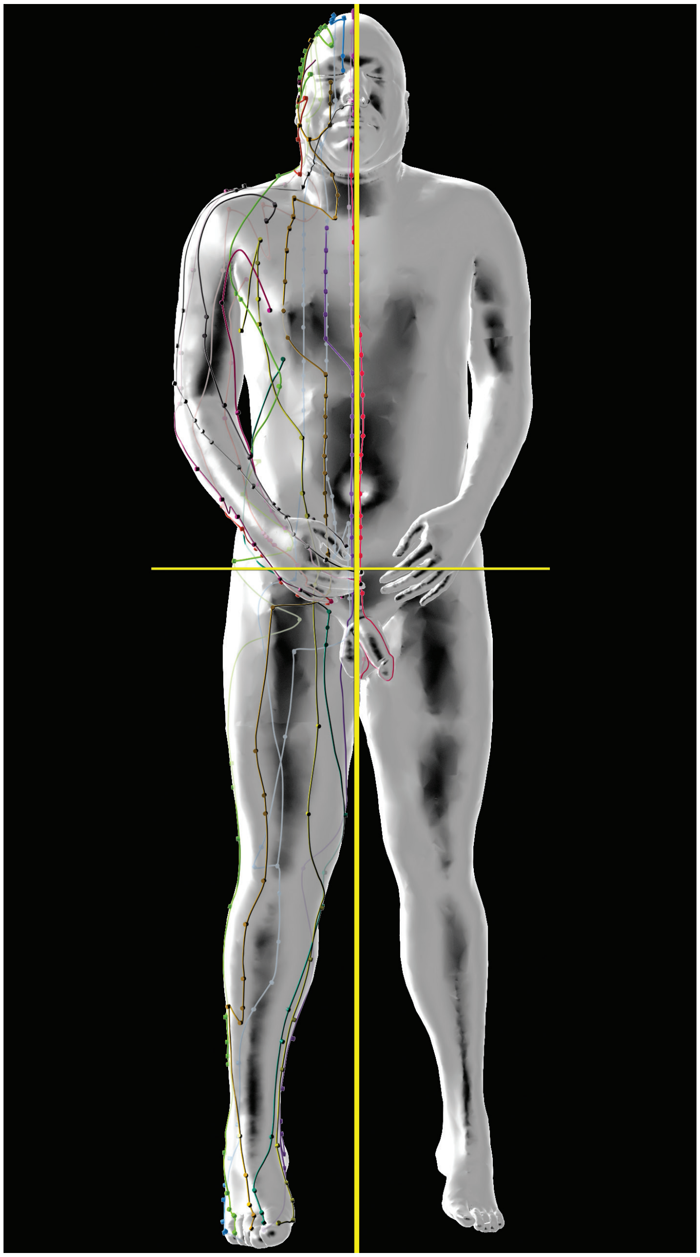

Figure 13-9B. CV 3, at the "Central Pole" of the body, designates the midpoint of the the vertical and horizontal axes, depicted by the intersecting yellow lines.

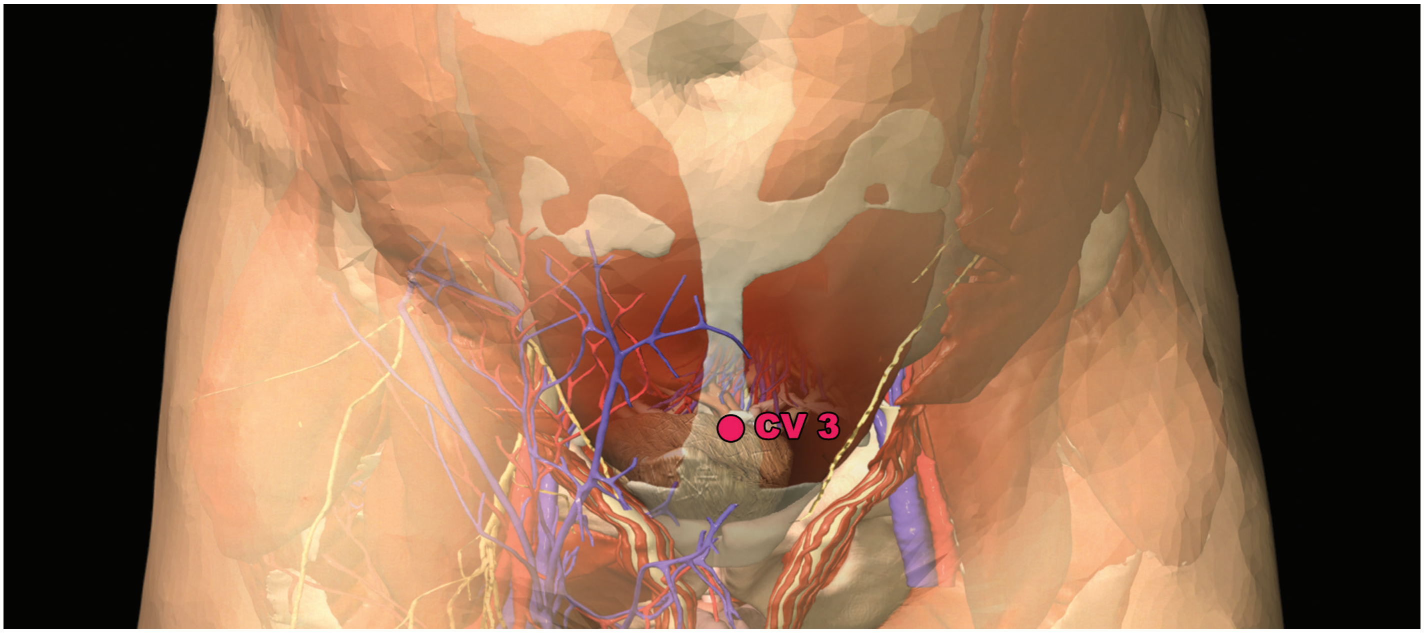

Figure 13-10. The name "Urgent Center" for CV 3 suggests the sense of urgency to void perceived, due to either a full bladder or myofascial dysfunction at CV 3 confusing the nervous system. This image reveals both the urinary bladder along with the overlying muscles of the abdominal wall, where the implicated trigger points may reside.

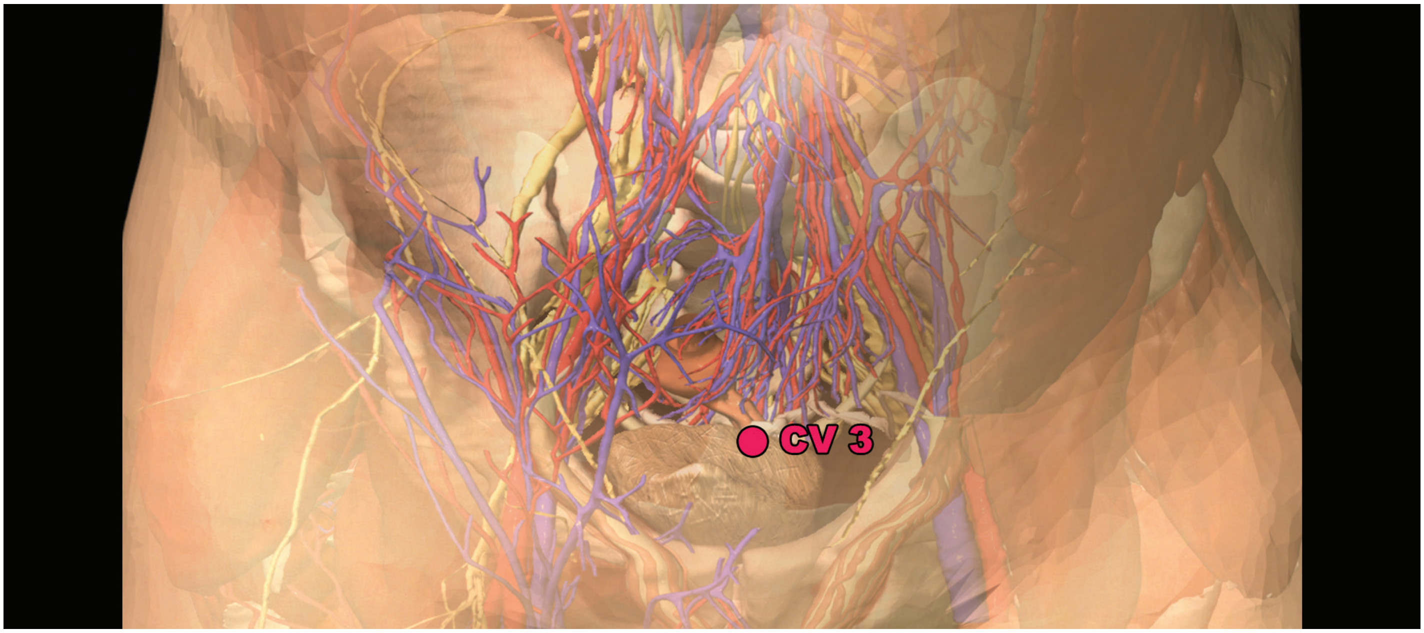

Figure 13-11. Removing the intestines from this image reveals the abundant vasculature of the pelvis. Remember that neuromodulation of the tibial nerve, thoracolumbar spinal cord segments, and sacral nerve roots by means of acupuncture and related techniques influences both circulation and neural input to pelvic organs such as the urinary bladder.

Nerves

- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3[14]):** The iliohypogastric nerve divides into anterior and lateral cutaneous branches. The lateral branch supplies the skin over the iliac crest while the ventral branch supplies the skin cranial to the pubic region. Supplies the skin of the hypogastric region and iliac crest. Also supplies the internal oblique and transverse abdominal muscles. The iliohypogastric nerve is the first nerve of the lumbar plexus.[15] The lumbar plexus forms from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or ventral to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.
- **Ilioinguinal nerve (L1, occasionally with T12):** Branches from the ilioinguinal nerve supply the skin of the scrotum and labium majus by means of its anterior scrotal and labial branches, respectively. Other branches supply the skin over the proximal and medial thigh. The ilioinguinal nerve accompanies the spermatic cord or round ligament of the uterus as it moves through the superficial inguinal ring, on the way to its destination of either the scrotum or labium majus, depending on the gender of the individual. The ilioinguinal nerve is involved in the afferent

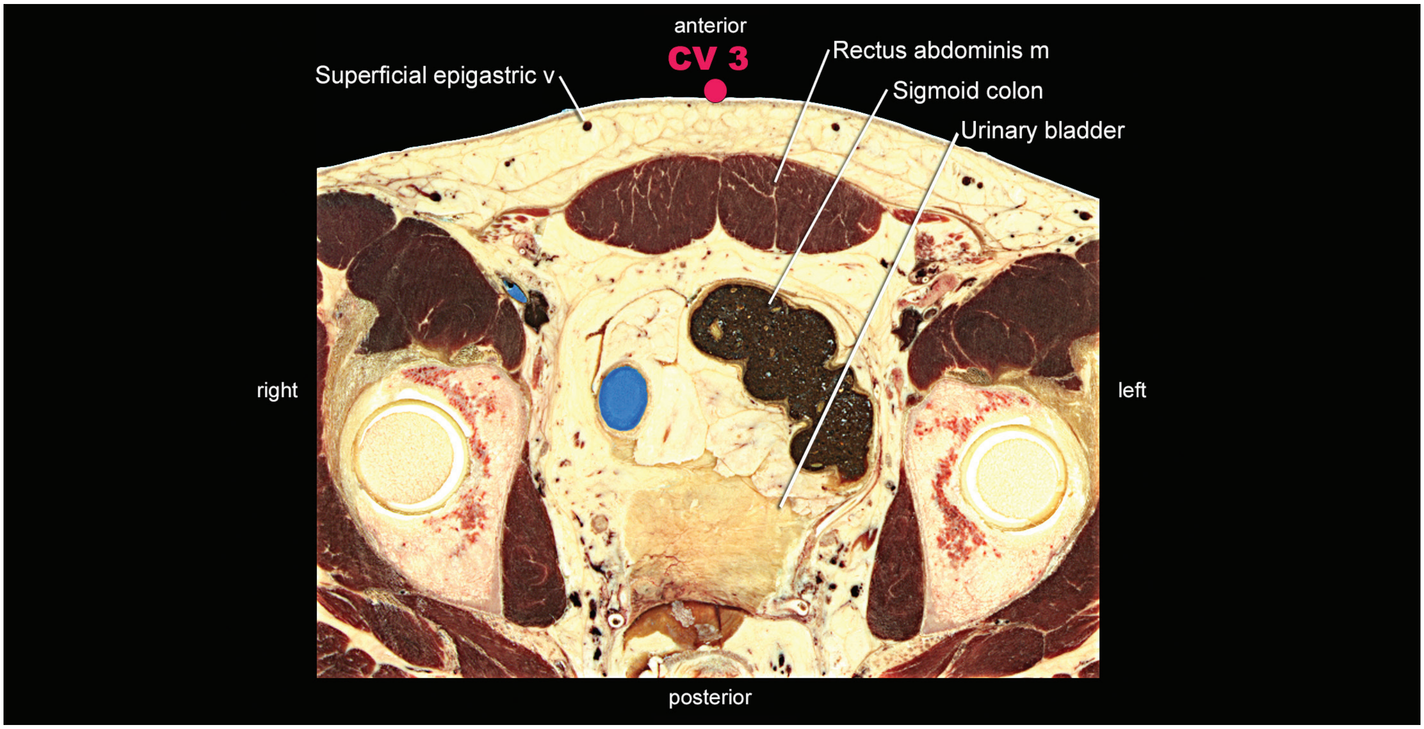

Figure 13-12. Safe needling depth for CV points depends upon patients' muscularity and adiposity. In this cross section of the male pelvis, note the distance between CV 3 and the sigmoid colon. The dorsal aspect of the urinary bladder shows well on this level but the colon is hiding its ventral component.

limb of the cremasteric reflex, along with the genitofemoral nerve (L1, L2). Branches of the ilioinguinal nerve include the anterior scrotal in males and the labial in females. Damage to the ilioinguinal nerve has been called an "infamous complication of inguinal hernia surgery".[16]

- **Thoracoabdominal nerves (T7-T12), ventral rami:** In the paravertebral region, the thoracic mixed autonomic, sensory, and motor nerves divide into a large ventral ramus and a smaller dorsal ramus in the paravertebral spaces. The ventral ramus of each side meets at the CV channel.

Clinical Relevance: CV 3, considered the Front Mu points for the urinary bladder, makes that association by means of overlap between nerves supplying the point as well as this and other pelvic organs through interneuronal connections in thoracolumbar spinal cord segments and the inferior hypogastric plexus.[1]

Gentle mechanical skin stimulation can inhibit transmission of afferent volleys from the bladder to parasympathetic segments in the sacrum. This signal interruption then inhibits rhythmic micturition contractions. The mechanism involves low-frequency inputs from low threshold cutaneous mechanoreceptors activated by gentle skin stimulation.[17] These findings indicate that CV 3 may hold value as a site for stimulation in acupuncture treatment protocols for urinary incontinence. Patients could learn to stimulate their own CV 3 as a daily routine to help resolve disorders of micturition through self-care.

The iliohypogastric nerve communicates extensively with the subcostal and ilioinguinal nerves. The iliohypogastric nerve pierces the transversus abdominis muscle. Some of its branches pierce the aponeurosis of the external oblique muscle. Communication between the genitofemoral and ilioinguinal or iliohypogastric nerves is common, causing overlap of sensory supply. Neurons from T11-L2 travel to the pelvic plexus via the inferior mesenteric plexus and hypogastric nerves.[18] Within the pelvic plexus, synapses take place between the plexus and postganglionic sympathetic fibers that project to the penis. Postganglionic sympathetic fibers consist of two types: cholinergic sympathetic and adrenergic sympathetic neurons. The cholinergic neurons function as vasodilators to the erectile tissue of the penis. Adrenergic neurons activate smooth muscle tissue in the epididymis, vas deferens, seminal vesicles, and prostate gland.

Nerves of the ventromedial abdominal wall form extensive communications between the internal oblique muscle and the transverse abdominis muscle.[19] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from the plexuses run in a craniocaudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively. The variability in spinal nerve origins for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy.

Crosstalk among nerves of the abdominal wall impacts anesthetic procedures such as nerve blocks and neuromodulatory approaches, including acupuncture and related techniques. For example, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually neuromodulate several spinal cord segments rather than only one level, thereby extending the treatment's impact more broadly.

Incisions often occur along the linea alba; i.e., the CV line. Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[20] Entrapment of thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[21] Entrapment of the ilioinguinal and iliohypogastric nerves can cause chronic, lower abdominal pain. Injection of local anesthetic relieves the pain, suggesting that acupuncture and related techniques could provide relief as well.

Nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction compress their turning points. Entrapment of an anterior branch of a spinal nerve within the rectus abdominis muscle or sheath produces pain in the lower abdomen and pelvis that sometimes simulates gynecologic disease in female patients. In men, entrapped cutaneous abdominal nerves can provoke penile pain. Scars increase the risk of nerve entrapment. Acupuncture may benefit these patients by releasing tension in the tissues and freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[22] Paresis of the abdominal wall can lead to mechanical complaints as well. Considering the benefits of acupuncture and related techniques for peripheral nerve injury, ilioinguinal nerve injury would likely respond to neuromodulation unless the nerves were severed completely. Chronic pain syndromes that take hold following iliohypogastric or ilioinguinal nerve injury during open inguinal hernia repair or gynecologic surgery should also be addressed with neuromodulation, in addition to adjunctive abdominal support and multimodal analgesia.

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area cranial to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the ventrolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart.

These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the internal thoracic, subclavian and brachiocephalic veins, and from there, into the superior vena cava.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; in more cranial regions, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep surface. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[23] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[24]

The valveless epigastric veins serve as collateral drainage routes for abdominopelvic blood. In the event of vena caval obstruction or ligation., the epigastric veins ferry venous blood craniad across the abdominal wall and into the internal thoracic, subclavian and brachiocephalic veins. From there, it empties into the superior vena cava.

Indications and Potential Point Combinations

- **Genitourinary or gynecologic problems: pain, amenorrhea, dysmenorrhea, vulvar pruritus, vaginal discharge, postpartum hemorrhage, dysuria, polyuria, urethritis, cystitis, impotence, spermatorrhea, infertility, retained placenta:** CV 3, SP 6, BL points over the sacrum, and other caudal body points to neuromodulate lumbosacral spinal cord segments. Other point options include: CV 3, CV 4, ST 29, SP 6, KI 3, and LR 3.[25]

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis**.[2]
- Acupuncture at CV 3, CV 6, HT 7, BL 23, BL 40, LU 9, LR 2, and LR 3 reportedly succeeded in treating pediatric **nocturnal enuresis**.[3]
- Electroacupuncture at CV 3, CV 4, and BL 32 benefited patients with **spinal cord injuries** by shortening the time to achieve a **balanced bladder,** as long as the treatments occurred within three weeks after injury.[4]
- Acupuncture reportedly benefited patients with **urinary retention** with the following points: CV 2, CV 3, CV 4, SP 6, SP 9, BL 23, BL 28, BL 32, and BL 39.[5]
- Acupuncture at CV 3, BL 23, BL 28, KI 3, SP 6, SP 9, LR 2 (or LR 3) provided effective prophylaxis of **recurrent lower urinary tract infection** in adult women.[6]
- Moxibustion at CV 3, CV 4, and CV 6 lessened symptoms of **post-stroke urinary problems.**[26]
- Manual acupuncture at CV 3, CV 6, GV 4, BL 23, BL 32, LI 4, ST 36, and KI 3, once weekly for ten weeks provided significant improvement in **anal continence** for patients with fecal incontinence via neuromodulation, in ways seemingly similar to sacral nerve stimulation.[7]
- Acupuncture at CV 3, CV 4, CV 6, GV 20, LI 4, BL 23, SP 6, and the Shenmen ear acupuncture point significantly improved symptoms of **primary dysmenorrhea** over those in the placebo group.[8]

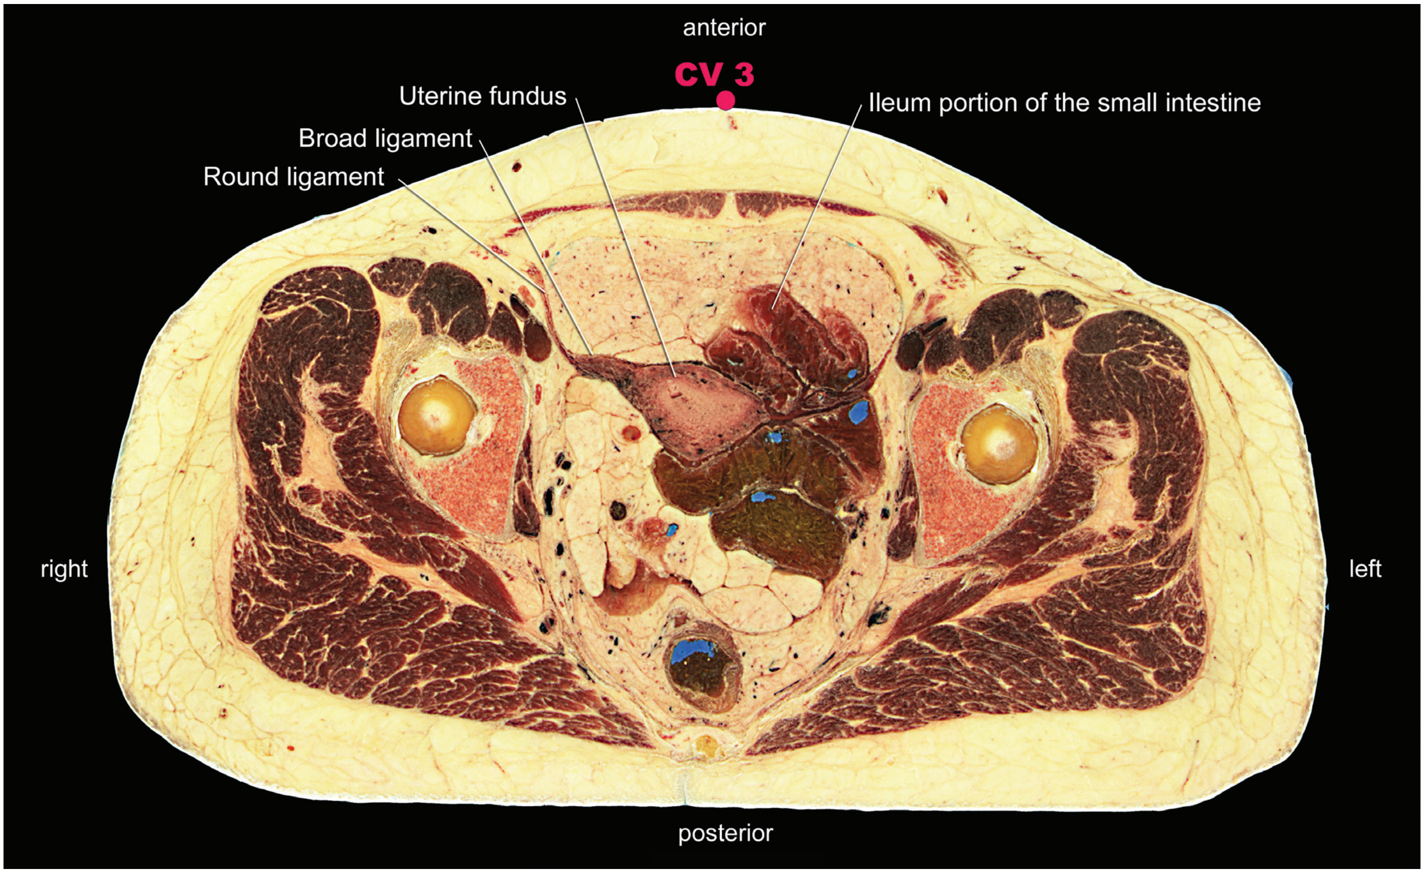

Figure 13-13. In the female pelvis, depicted here, CV 3 relates to the uterus along with the bladder.

- A case series reported that both acupuncture and moxibustion at BL 23, BL 32, BL 54, SP 6, CV 3, CV 4, KI 12, and LR 3 were effective in treating **erectile dysfunction.**[9]
- Needling of BL 67 and CV 3 effectively treated **retained placenta** in a case series.[10]
- Moxibustion at CV 3, CV 4, CV 5, CV 7, GV 4, and BL 18, BL 22, BL 23, and BL 52 significantly increased clinical pregnancy rate when introduced as an adjunctive treatment in women receiving in vitro fertilization (IVF) after embryo implantation failed.[27]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV19, LU9, and LR 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[11]
- Needling and mild moxibustion delivered to BL 23, BL 25, BL 54, CV 3, CV 4, CV 6, SP 6, and ST 28 effectively resolved **chronic prostatitis.**[12]

CV 4

Guan Yuan "Gate of Origin", "Pass Head"

On the ventral midline, 2 cun cranial to the cranial border of the symphysis pubis, 3 cun caudal to the umbilicus.

NOTE: Do not needle in pregnant women except to induce labor. Even then, avoid deep needling.

Fascia

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Median umbilical ligament:** This remnant of the urachus had at one time joined the apex of the fetal bladder to the umbilicus. The median umbilical ligament represents the embryologic remnant of the cloaca and allantois. Coursing from the urinary bladder to the umbilicus, the median umbilical fold covers the median umbilical ligament.

Clinical Relevance: Urachal remnant disease, though rare, usually presents in the neonatal period but may be found in older children suffering from acute abdominal pain. Differential diagnoses include appendicitis, inflammatory bowel disease, cystitis, strangulated umbilical hernia, abscess, Meckel's diverticulum, and more.[22] Congenital anomalies include persistent urachus, urachal sinus, urachal cyst, and a vesicourachal diverticulum. Signs and symptoms of urachal infection include fever, pain in the lower midline, urinary dysfunction and/or infection, and a palpable suprapubic mass. While acupuncture and related techniques may assist with recovery, patients with an infected urachus may require surgical excision of the urachal remnant and antibiotics. Do not delay appropriate diagnosis and treatment in favor of trying acupuncture for these patients until medically or surgically indicated measures have been instituted.

Nerves

- **Subcostal nerve (T12):** Supplies the lowest portions of the external oblique muscles as well as the skin over the hip and anterior superior iliac spine.
- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3[23]):** The iliohypogastric nerve divides into anterior and lateral cutaneous branches. The lateral branch supplies the skin over the iliac crest while the ventral branch supplies the skin cranial to the pubic region. Supplies the skin of the hypogastric region and iliac crest. Also supplies the internal oblique and transverse abdominal muscles. The iliohypogastric nerve is the first nerve of the lumbar plexus.[24] The lumbar plexus forms from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or ventral to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.
- **Thoracoabdominal nerves (T7-T12), ventral rami:** In the paravertebral region, the thoracic mixed autonomic, sensory, and motor nerves divide into a large ventral ramus and a smaller

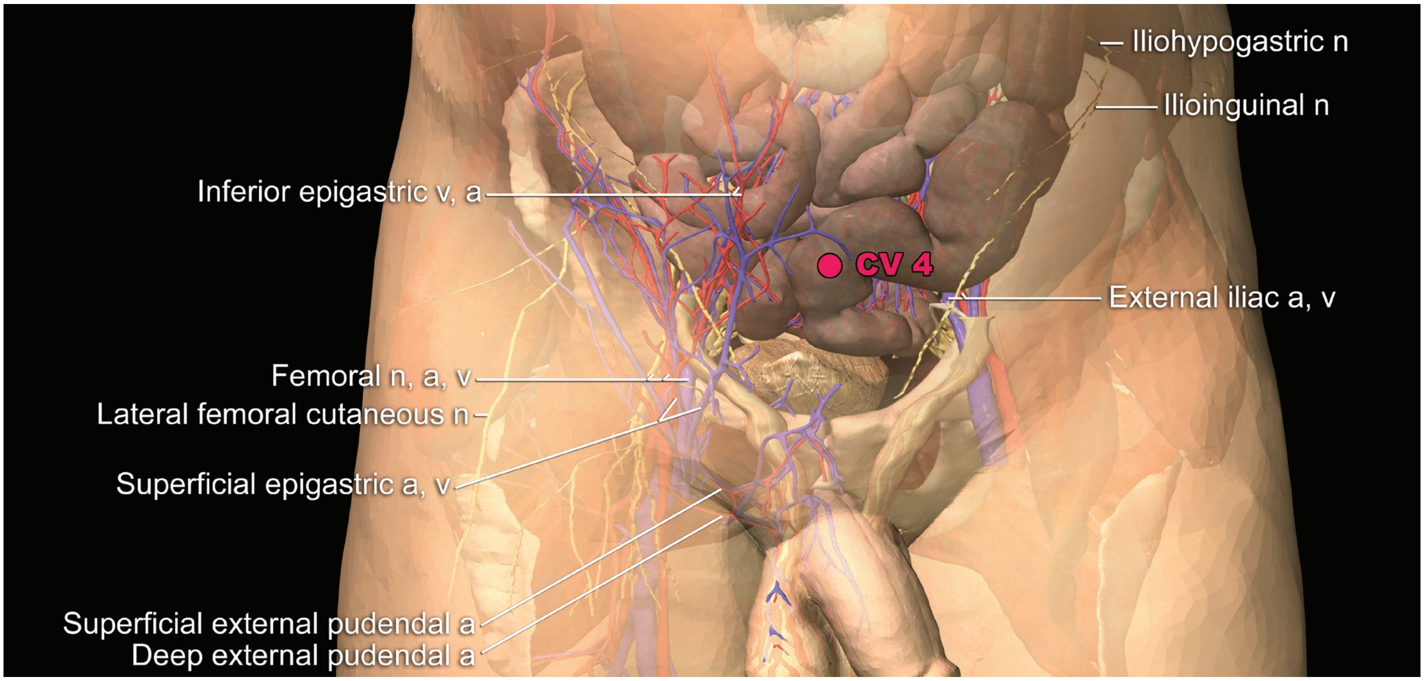

Figure 13-14A. CV 4 has almost thirty alternate names, with many alluding to the uterus ("blood chamber"), fetal development, fetal passage through this region during delivery, "cinnabar field" (Dantian), "elixir field", or "source of life".[32,33] While these names indicate uniquely female aspects, the point's action as a Front Mu point for the small intestine applies to both genders.

dorsal ramus in the paravertebral spaces. The ventral ramus of each side meets at the CV channel.

Clinical Relevance: CV 4, considered the Front Mu point for the small intestine, may impact digestion and genitourinary function by sending somatic afferent stimulation into spinal cord segments that supply both the tissues affected by acupuncture and the associated organs.

Neuroanatomically, CV 4 may, at least in part, influence autonomic input to the genitalia through its relationship to the inferior hypogastric plexus.[1]

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area cranial to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the ventrolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the internal thoracic, subclavian and brachiocephalic veins, and from there, into the superior vena cava.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; in more cranial regions, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep surface. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[25] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[26]

The valveless epigastric veins serve as collateral drainage routes for abdominopelvic blood. In the event of vena caval obstruction or ligation., the epigastric veins ferry venous blood craniad across the abdominal wall and into the internal thoracic, subclavian and brachiocephalic veins. From there, it empties into the superior vena cava.

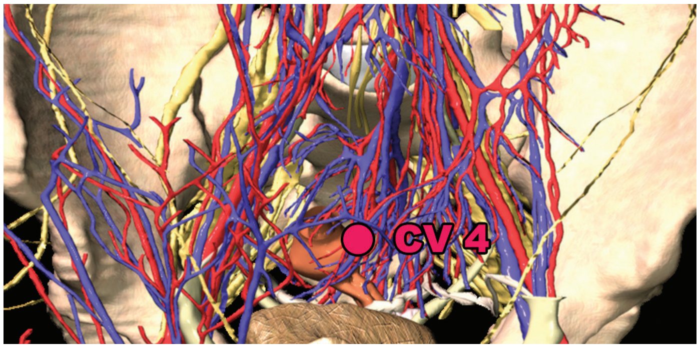

Figure 13-14B. This close-up image of CV 4, the bladder, and the ventral sacrum reveals the sacral nerve roots that supply the bladder and uterus – organs that CV 4 may impact by dint of overlapping innervation of the point and pelvic viscera.

Indications and Potential Point Combinations

- **Reproductive system problems, including seminal discharge, erectile dysfunction, vaginal discharge, menstrual problems (metrorrhagia, amenorrhea, dysmenorrhea), uterine prolapse, postpartum hemorrhage:** CV 4, CV 6,. BL 23, SP 6, GV 20.
- **Urinary problems or voiding difficulty, including dysuria, enuresis, and urethritis:** CV 4, CV 3, BL 28, BL 23.
- **Diarrhea, dysentery:** CV 4, BL 21, BL 27, ST 36, SP 6.
- **Lower abdominal pain:** CV 4, CV 6, ST 25, ST 36, BL 25.
- **Hernia:** CV 4, ST 29, ST 30, local points (cranial, caudal, medial, and lateral to the hernia).
- **Hypotension, shock:** CV 4, HT 9, GV 20, GV 26 (if necessary).

Evidence-Based Applications

- Electroacupuncture at CV 3, CV 4, and BL 32 benefited patients with **spinal cord injuries** by shortening the time to achieve a balanced bladder , as long as the treatments occurred within three weeks after injury.[2]
- Acupuncture reportedly benefited patients with **urinary retention** in a Chinese clinical trial with the following points: CV 2, CV 3, CV 4, SP 6, SP 9, BL 23, BL 28, BL 32, and BL 39.[3]
- Moxibustion at CV 3, CV 4, and CV 6 lessened symptoms of **post-stroke urinary problems.**[27]
- Acupuncture at SP 6, BL 39, BL 28, and CV 4 provided significant improvement in women diagnosed as having **overactive bladder with urge incontinence.**[4]
- Acupuncture at BL 23, BL 28, and GV 4 or CV 4, CV 6, and SP 6 benefited patients with diurnal symptoms associated with **idiopathic bladder instability.**[5]
- Points affecting ovarian function in rats with experimentally induced **inflammation of the ovary** included CV 4, Zigong (EX-CA 1, lateral to SP 13), BL 23, GV 4, GV 1, CV 1, SP 6, ST 36, CV 12, BL 18, and GV 4.6 Of these, CV 4, Zigong (EX-CA 1), BL 23, and GV 4 delivered the most impact.
- Acupuncture at CV 4, CV 6, BL 23, SP 6, LI 4, GB 34, and GV 20 significantly improved the symptoms of **primary dysmenorrhea** up to two years after therapy.[7]
- Moxibustion at CV 3, CV 4, CV 5, CV 7, GV 4, and BL 18, BL 22,

BL 23, and BL 52 significantly **increased pregnancy rate** when introduced as an adjunctive treatment in women receiving in vitro fertilization (IVF) after embryo implantation failed.[28]

- Electroacupuncture at CV 1, CV 2, CV 4, CV 5, BL 21, BL 23, and BL 32 benefited patients with **persistent sensory urgency after transurethral resection of the prostate.**[8]
- Acupuncture at CV 4, BL 23, BL 25, and ST 25 offers an alternative to pharmacologic **sedation and analgesics in patients receiving extracorporeal shockwave lithotripsy** who are unable to tolerate medication.[9]
- Electroacupuncture at 10 Hz, delivered to LR 3-SP 6, ST 28-EX-CA1, and CV 6-CV 4 demonstrated that acupuncture can **reduce uterine artery impedance.** Treatment of this sort may provide an alternative approach to preventing pre-eclamsia or intrauterine growth restriction in high risk women.[10]
- A case series reported that both acupuncture and moxibustion at BL 23, BL 32, BL 54, SP 6, CV 3, CV 4, KI 12, and LR 3 were effective in treating **erectile dysfunction.**[11]
- Electroacupuncture at CV 4, GV 20, SP 6, KI 3, and HT 7 may have afforded a modulating positive effect on psychogenic and **non-psychogenic erectile dysfunction.** It improved the quality of erection and restored sexual activity in 39% of patients.[12]
- Chinese drug injection at CV 1, CV 4, and LR 10 led to improvements in functional and arterial low-level blood supply **erectile dysfunction** in a Chinese research trial.[13]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LR 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[14]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[15]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in improvement in **sperm quality**, specifically in the ultrastructural integrity of spermatozoa.[16]
- Needling and mild moxibustion delivered to BL 23, BL 25, BL 54, CV 3, CV 4, CV 6, SP 6, and ST 28 effectively resolved **chronic prostatitis.**[17]
- Acupuncture and moxibustion at ST 25, ST 36, ST 37, CV 4, SP 6, SP 9, BL 20, BL 21, and BL 25 benefited patients with **chronic nonspecific ulcerative colitis** in a case series.[18]
- A case series reported that acupuncture and moxibustion at ST 25 and CV 4 effectively improved symptoms in **patients with chronic colitis.**
- Electroacupuncture at ST 36, ST 37, ST 25, ST 28, CV 4, and CV 6 alleviated **constipation** through activation of the parasympathetic nervous system.[29]
- Electroacupuncture at CV 12 and CV 4 in **diabetic** rats induced secretion of endogenous β-endorphin; this reduced plasma glucose concentration in an insulin-dependent manner.[19]
- Moxibustion at CV 4 in tumor-bearing mice **improved immune function and regulation.**[20]
- Indirect moxibustion applied to CV 4 and CV 8 three times weekly for four weeks increased catalase activity significantly, suggesting support of the **antioxidant defense system** through heating of these points.[30]
- Electroacupuncture at CV 4 and CV 12 modulated the limbic-prefrontal functional network, which overlaps with functional circuits associated with **cognitive and emotional regulation.**[31]
- Acupuncture at abdominal points augmented the benefits of local points when combined into a treatment involving CV 4, CV 12, ST 26, and SP 15, in addition to ST 34, ST 35, GB 33, GB 34, SP 10, and EX-LE 4 for **osteoarthritis of the knee.**[21]

CV 5

Shi Men "Stone Gate"

On the ventral midline, 2 cun caudal to the umbilicus, 3 cun cranial to the cranial border of the symphysis pubis.

Fascia

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Median umbilical ligament:** This remnant of the urachus had at one time joined the apex of the fetal bladder to the umbilicus. The median umbilical ligament represents the embryologic remnant of the cloaca and allantois.

Coursing from the urinary bladder to the umbilicus, the median umbilical fold covers the median umbilical ligament.

Clinical Relevance: Urachal remnant disease, though rare, usually presents in the neonatal period but may be found in older children suffering from acute abdominal pain. Differential diagnoses include appendicitis, inflammatory bowel disease, cystitis, strangulated umbilical hernia, abscess, Meckel's diverticulum, and more.[4] Congenital anomalies include persistent urachus, urachal sinus, urachal cyst, and a vesicourachal diverticulum. Signs and symptoms of urachal infection include fever, pain in the lower midline, urinary dysfunction and/or infection, and a palpable suprapubic mass. While acupuncture and related techniques may assist with recovery, patients with an infected urachus may require surgical excision of the urachal remnant and antibiotics. Do not delay appropriate diagnosis and treatment in favor of trying acupuncture for these patients until medically or surgically indicated measures have been instituted.

Nerves

- **Subcostal nerve (T12):** Supplies the lowest portions of the external oblique muscles as well as the skin over the hip and anterior superior iliac spine.
- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3[5]):** The iliohypogastric nerve divides into anterior and lateral cutaneous branches. The lateral branch supplies the skin over the iliac crest while the ventral branch supplies the skin cranial to the pubic region. Supplies the skin of the hypogastric region and iliac crest. Also supplies the internal oblique and transverse abdominal muscles. The iliohypogastric nerve is the first nerve of the lumbar plexus.[6] The lumbar plexus forms from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or ventral to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.
- **Thoracoabdominal nerves (T7-T12), ventral rami:** In the paravertebral region, the thoracic mixed autonomic, sensory, and motor nerves divide into a large ventral ramus and a smaller dorsal ramus in the paravertebral spaces. The ventral ramus of each side meets at the CV channel.

Clinical Relevance: CV 5, considered the Front Mu point for the elusive structure called the "Triple Heater", may impact digestion and genitourinary function by sending somatic afferent stimulation into spinal cord segments that supply both the tissues affected by acupuncture and the associated organs.

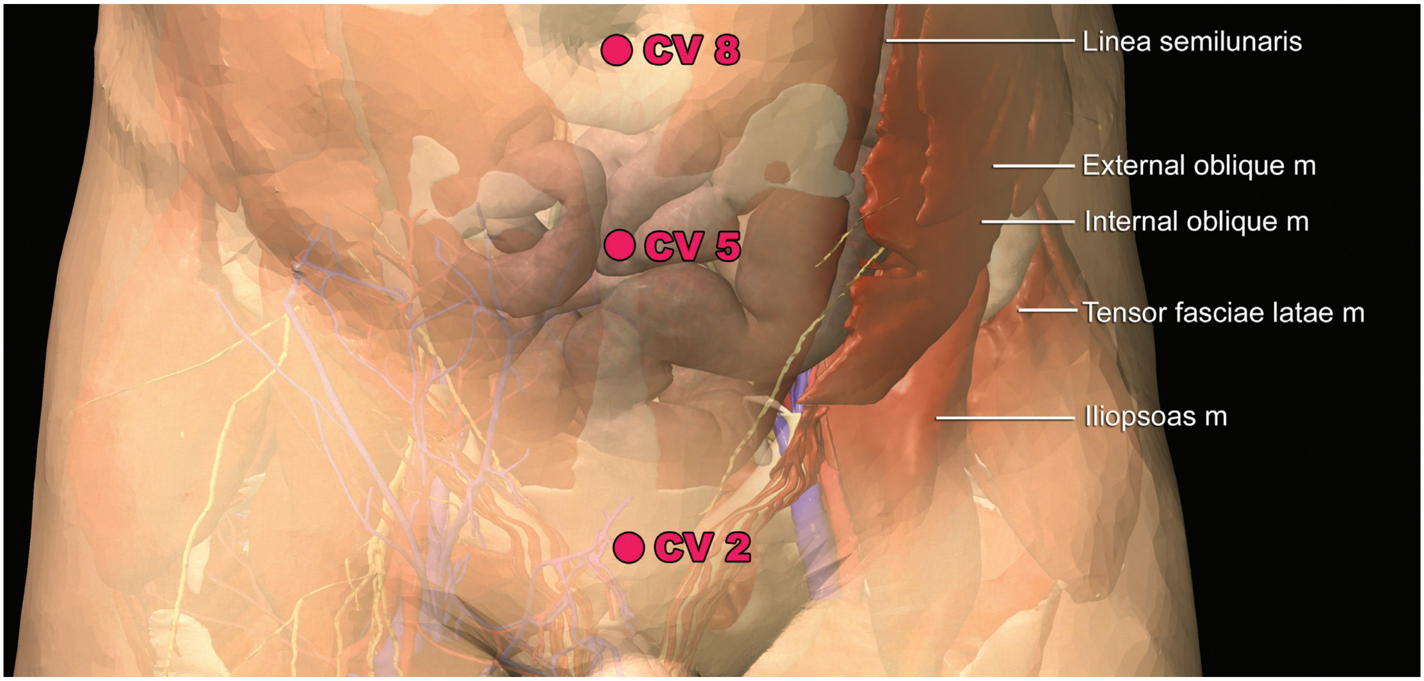

Figure 13-16A. The descriptive term for CV 5, "Stone Gate" alludes to hard, stone-like, masses in the intestines deep to CV 5, as shown here, or to concretions in the urinary tract, described in Figure 13-16B.

Neuroanatomically, CV 5 may, at least in part, influence autonomic input to the genitalia through its relationship to the inferior hypogastric plexus.[1]

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area cranial to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the ventrolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the internal thoracic, subclavian and brachiocephalic veins, and from there, into the superior vena cava.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; in more cranial regions, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep surface. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[7] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[8]

The valveless epigastric veins serve as collateral drainage routes for abdominopelvic blood. In the event of vena caval obstruction or ligation, the epigastric veins ferry venous blood craniad across the abdominal wall and into the internal thoracic, subclavian and brachiocephalic veins. From there, it empties into the superior vena cava.

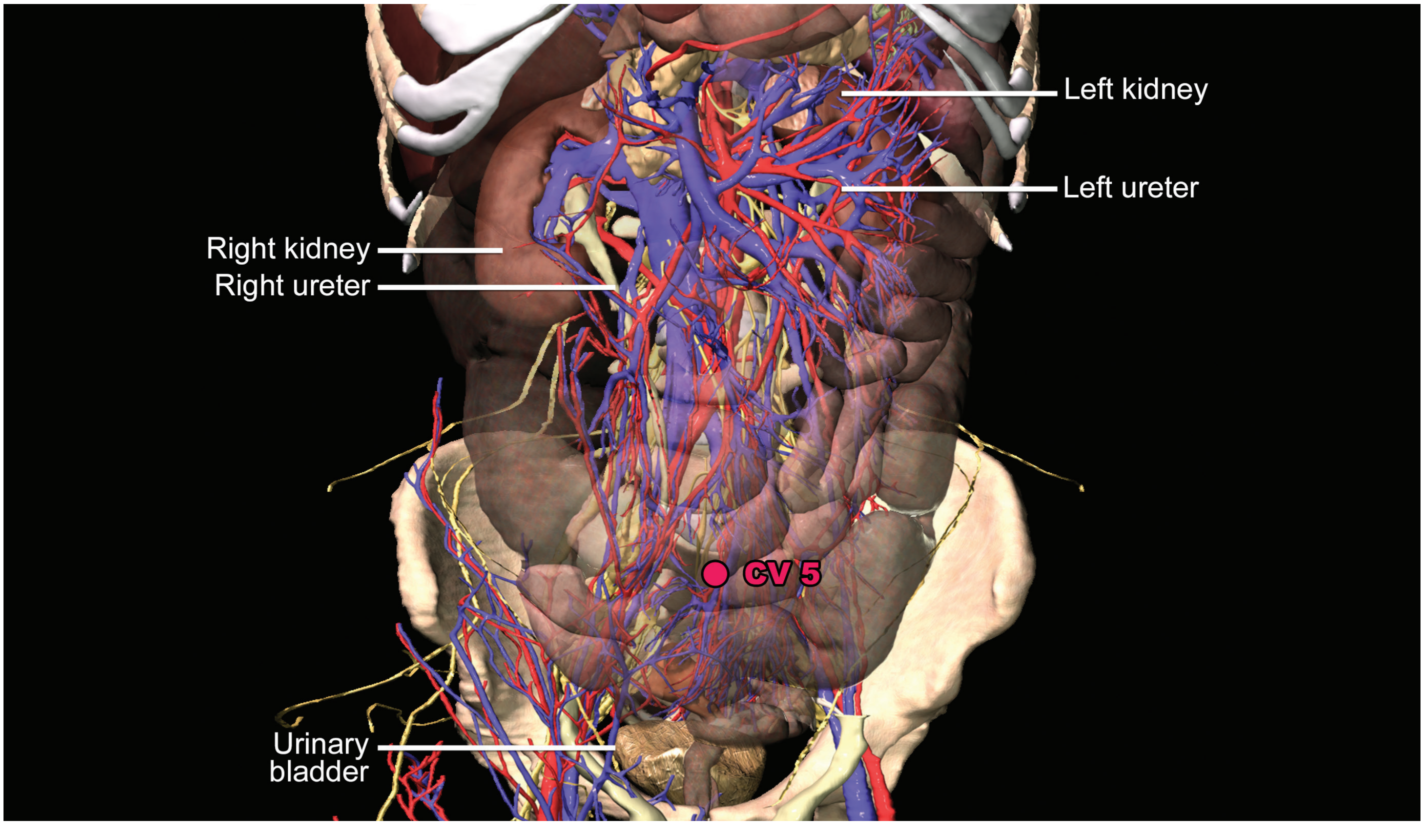

Figure 13-16B. Ureteroliths traversing from kidney to bladder incite pain, inflammation, and possible obstruction. Sympathetic innervation of the ureter arises from the lower fibers of the renal plexus (T11-T12), the superior hypogastric plexus, and the hypogastric nerve and inferior hypogastric plexus.[10] Acupuncture and related techniques applied to CV 5, shown in this image, may neuromodulate the same spinal cord segments that supply the ureter with sympathetic innervation. (The ureter derives its parasympathetic control from the vagus nerve.)

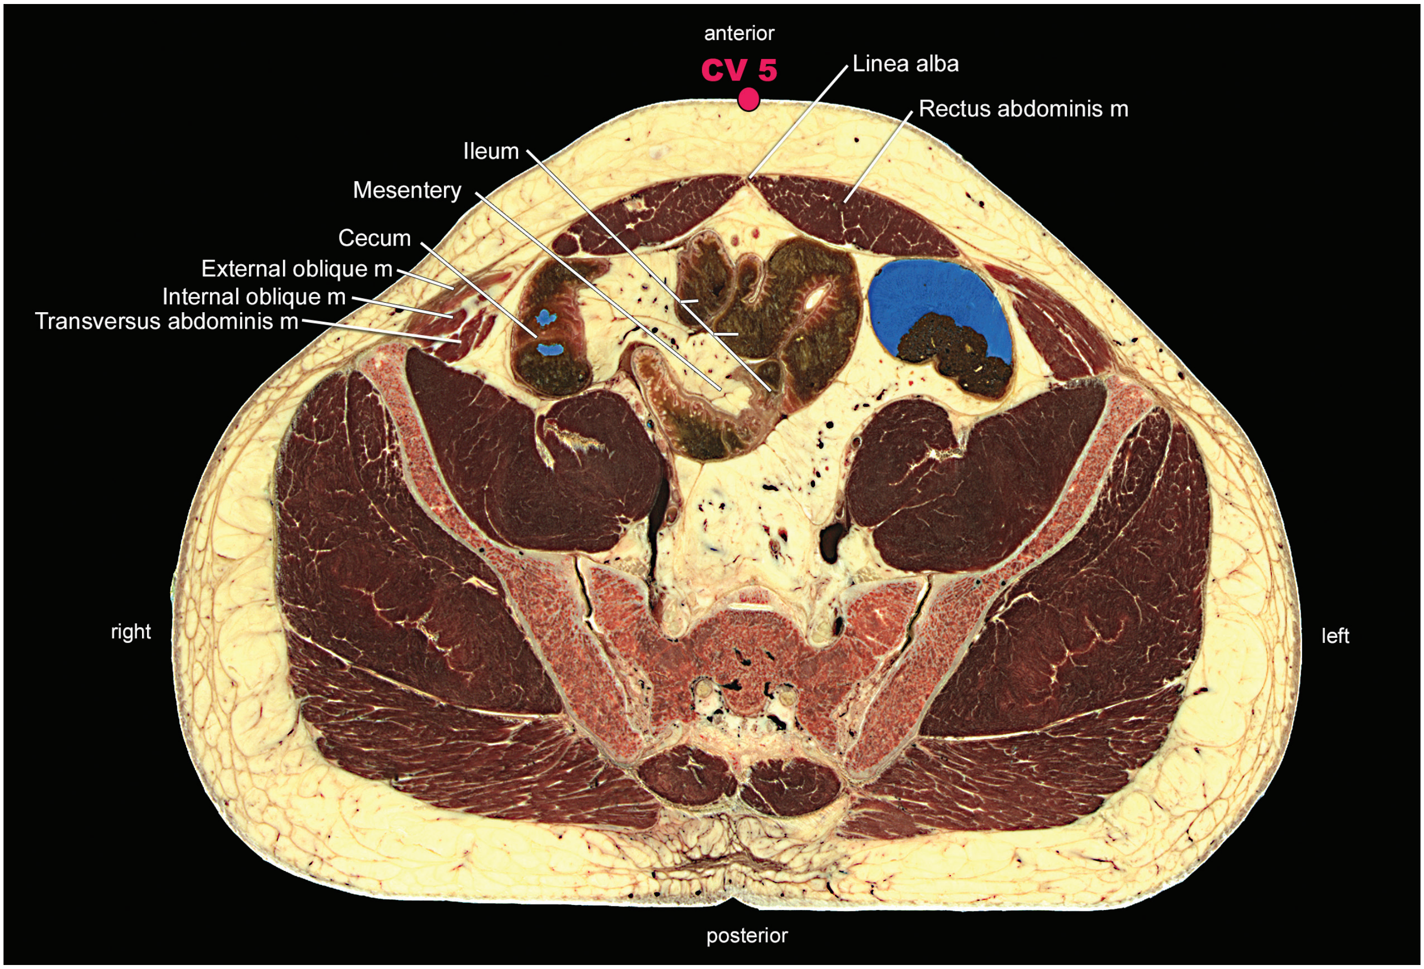

Figure 13-17. This cross-section explains how, by palpating CV 5 between the rectus abdominis muscles, one could find hard, stone-like structures in the ileum of an obstipated or constipated patient.

Indications and Potential Point Combinations

- **Ascites:** CV 5, CV 12, CV 14, KI 16, ST 25, ST 36, KI 27, BL 39, GV 20.
- **Ureterolithiasis:** CV 5, CV 3, GB 25, GB 26, BL 23, BL 52, BL 10, ST 36.
- **Myasthenia gravis:** CV 5, CV 4, CV 12, CV 17, GB 34, ST 36, GV 14, GV 20.

Evidence-Based Applications

- Electroacupuncture at CV 1, CV 2, CV 4, CV 5, BL 21, BL 23, and BL 32 benefited patients with **persistent sensory urgency** after transurethral resection of the prostate.[1]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LR 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[2]
- Electroacupuncture "warming therapy" applied to CV 5, CV 4, CV 12, CV 17, and GB 34 combined with pyridostigmine led to a significantly better therapeutic effect on **myasthenia gravis** than that provided by pyridostigmine alone, according to a Chinese study.[3]
- Moxibustion at CV 3, CV 4, CV 5, CV 7, GV 4, and BL 18, BL 22, BL 23, and BL 52 significantly **increased pregnancy rate** when introduced as an adjunctive treatment in women receiving in vitro fertilization (IVF) after embryo implantation failed.[9]

CV 6

Qi Hai "Sea of Qi"

On the ventral midline, 1.5 cun caudal to the umbilicus, 3.5 cun cranial to the cranial border of the symphysis pubis.

Fascia

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of thevabdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Median umbilical ligament:** This remnant of the urachus had at one time joined the apex of the fetal bladder to the umbilicus. The median umbilical ligament represents the embryologic remnant of the cloaca and allantois. Coursing from the urinary bladder to the umbilicus, the median umbilical fold covers the median umbilical ligament.

Clinical Relevance: Urachal remnant disease, though rare, usually presents in the neonatal period but may be found in older children suffering from acute abdominal pain. Differential diagnoses include appendicitis, inflammatory bowel disease, cystitis, strangulated umbilical hernia, abscess, Meckel's diverticulum, and more.[11] Congenital anomalies include persistent urachus, urachal sinus, urachal cyst, and a vesicourachal diverticulum. Signs and symptoms of urachal infection include fever, pain in the lower midline, urinary dysfunction and/or infection, and a palpable suprapubic mass. While acupuncture and related techniques may assist with recovery, patients with an infected urachus may require surgical excision of the urachal remnant and antibiotics. Do not delay appropriate diagnosis and treatment in favor of trying acupuncture for these patients until medically or surgically indicated measures have been instituted.

- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3[12]):** The iliohypogastric nerve divides into anterior and lateral cutaneous branches. The lateral branch supplies the skin over the iliac crest while the ventral branch supplies the skin cranial to the pubic region. Supplies the skin of the hypogastric region and iliac crest. Also supplies the internal oblique and transverse abdominal muscles. The iliohypogastric nerve is the first nerve of the lumbar plexus.[13] The lumbar plexus forms from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or ventral to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.
- **Thoracoabdominal nerves (T7-T12), ventral rami:** In the paravertebral region, the thoracic mixed autonomic, sensory, and motor nerves divide into a large ventral ramus and a smaller dorsal ramus in the paravertebral spaces. The thoracoabdominal nerves, ventral rami, also supply the periphery of the thoracic diaphragm. The ventral ramus of each side meets at the CV channel.

Clinical Relevance: Nerves supplying CV 6 overlap with

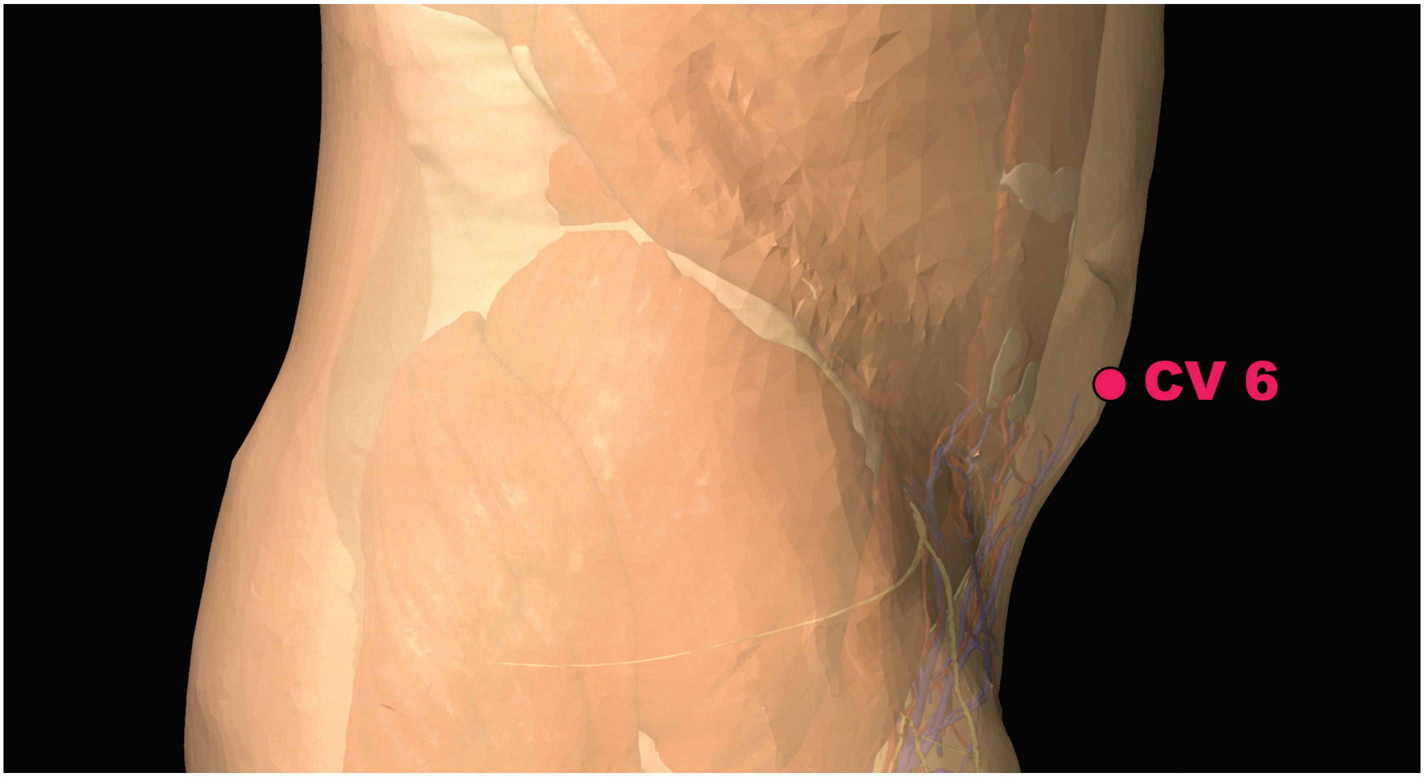

Figure 13-18. The name "Sea of Qi" for CV 6 connotes the bulge in the belly that appears in this image. The abdomen may protrude at this site due to accumulation of fat or the growth of a fetus (in women).

activities of other points in the caudal abdomen; namely, they neuromodulate caudal abdominal visceral activities pertaining to digestive and genitourinary functions.

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T11):** Supplies the ventral abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Nerves supplying CV 6 overlap with activities of other points in the caudal abdomen; namely, they neuromodulate caudal abdominal visceral activities pertaining to digestive and genitourinary functions.

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area cranial to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the ventrolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the internal thoracic, subclavian and brachiocephalic veins, and from there, into the superior vena cava.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; in more cranial regions, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep surface. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[14] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[15]

The valveless epigastric veins serve as collateral drainage routes for abdominopelvic blood. In the event of vena caval obstruction or ligation, the epigastric veins ferry venous blood craniad across the abdominal wall and into the internal thoracic, subclavian and brachiocephalic veins. From there, it empties into the superior vena cava.

Indications and Potential Point Combinations

- **Uterine fibroids, menstrual irregularities, dysmenorrhea:** CV 6, CV 4, CV 3, ST 28, KI 3, SP 6.
- **Fatigue:** CV 6, SP 6, ST 36, PC 6, GV 20.
- **Infertility, impotence:** CV 6, GV 4, BL 23, GV 20, SP 6, KI 3.
- **Constipation, abdominal distension:** CV 6, CV 4, BL 25, BL 27, ST 36, GV 20.

Evidence-Based Applications

- Electroacupuncture at 10 Hz, delivered to LR3-SP6, ST 28-EX-CA 1 (also known as Zigong, located 4 cun below the umbilicus and 3 cun lateral to CV 3), and CV 6-CV 4 demonstrated that acupuncture can reduce uterine artery impedance. Because **preeclampsia** may constitute a circulatory maladaptation disease resulting from defective trophoblastic invasion of the maternal spiral arteries, this type of treatment may provide an alternative means of preventing pre-eclamsia or intrauterine growth restriction in high risk women.[1]
- Dry needling of CV 6, CV 4, CV 3, GV 20, LI 4, BL 23, SP 6, GB 34, and auricular Shen Men significantly outperformed placebo for women with **primary dysmenorrhea** and was effective for at least one year.[2]
- Acupuncture at CV 2, CV 6, CV 12, LI 4, LI 11, PC 6, LR 3, SP 6, ST 36, and GV 20 reduced myalgia, mastalgia, and dysmenorrheal complaints in women with **premenstrual syndrome.**[16]
- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis**.[3]
- Acupuncture at CV 6, CV 12, CV 17, ST 36, and SP 10 conferred protective effects on cognitive impairments caused by **multi-infarct dementia** in rats, suggesting it may benefit patients with vascular dementia.[4]
- Acupuncture at CV 6, CV 12, CV 17, ST 36, and SP 10 provided significant benefits for patients with **vascular dementia**.[17] Specifically, they exhibited improvements on the mini-mental status examination and Hasegawa's dementia scale.
- Acupuncture at BL 23, BL 28, and GV 4 or CV 4, CV 6, and SP 6 benefited patients with diurnal symptoms associated with **idiopathic bladder instability**.[5]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LR 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome)**.[6]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected

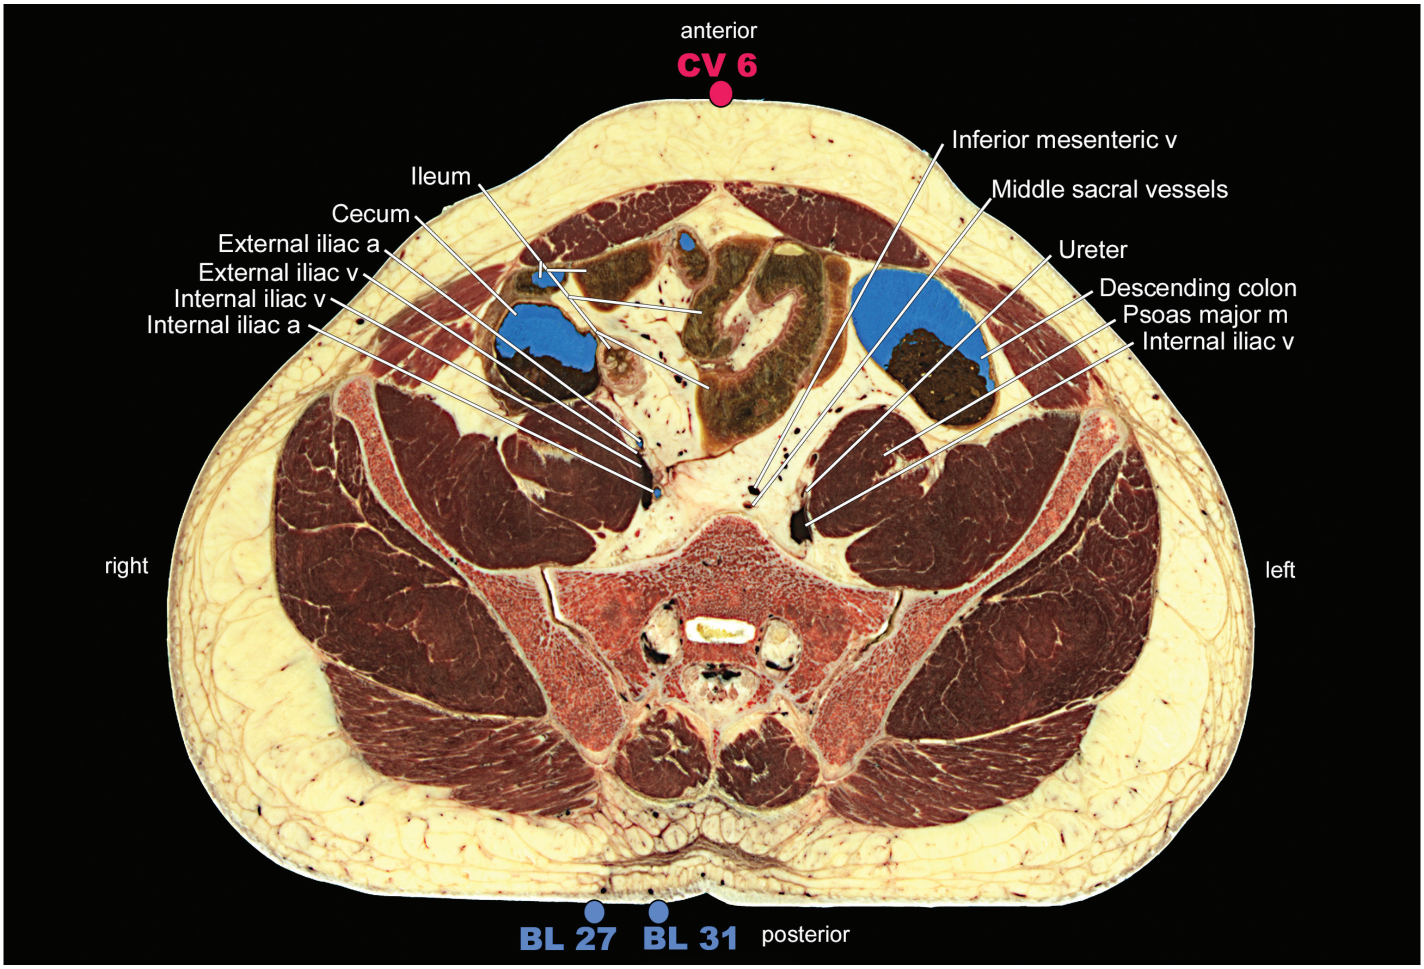

Figure 13-19. In keeping with the term, "Sea of Qi", note the subcutaneous tissue mound deep to the point.

according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[7]

- Needling and mild moxibustion delivered to BL 23, BL 25, BL 54, CV 3, CV 4, CV 6, SP 6, and ST 28 effectively resolved **chronic prostatitis.**[8]
- Dry needling of CV 6, CV 3, GV 4, BL 23, LI 4, ST 36, and KI 3 neuromodulates recto-anal function in a manner similar to sacral nerve stimulation and showed benefit for patients with **fecal incontinence.**[9]
- Acupuncture at CV 6, ST 36, SP 6, and PC 6 led to small increases in **cerebral oxygen saturation** levels and a significant increase in mean blood flow velocity in the middle cerebral artery during acupuncture.[10]

CV 7

Yin Jiao "Yin Intersection"

On the ventral midline, 1 cun caudal to the umbilicus, 4 cun cranial to the cranial border of the symphysis pubis.

Fascia

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Median umbilical ligament:** This remnant of the urachus had at one time joined the apex of the fetal bladder to the umbilicus. The median umbilical ligament represents the embryologic remnant of the cloaca and allantois. Coursing from the urinary bladder to the umbilicus, the median umbilical fold covers the median umbilical ligament.

Clinical Relevance: Urachal remnant disease, though rare, usually presents in the neonatal period but may be found in older children suffering from acute abdominal pain. Differential diagnoses include appendicitis, inflammatory bowel disease, cystitis, strangulated umbilical hernia, abscess, Meckel's diverticulum, and more.[2] Congenital anomalies include persistent urachus, urachal sinus, urachal cyst, and a vesicourachal diverticulum. Signs and symptoms of urachal infection include fever, pain in the lower midline, urinary dysfunction and/or infection, and a palpable suprapubic mass. While acupuncture and related techniques may assist with recovery, patients with an infected urachus may require surgical excision of the urachal remnant and antibiotics. Do not delay appropriate diagnosis and treatment in favor of trying acupuncture for these patients until medically or surgically indicated measures have been instituted.

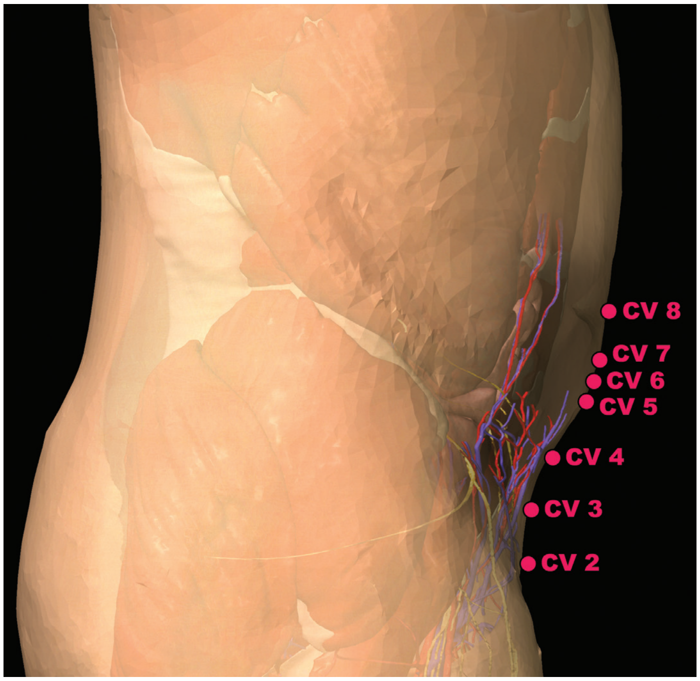

Figure 13-20. This lateral view of the CV points on the caudal abdomen offers a unique perspective of the superficial and deep vessels that participate in the periumbilical arterial and venous anastomoses. The presence of anastomosing vessels on the "Yin" surface of the body, i.e., the abdomen, explain how CV 7 earned the title, "Yin Intersection".

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T11):** Supplies the ventral abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Nerves supplying CV 7 overlap with activities of other points in the caudal abdomen; namely, they neuromodulate caudal abdominal visceral activities pertaining to digestive and genitourinary functions.

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area cranial to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the ventrolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the internal thoracic, subclavian and brachiocephalic veins, and from there, into the superior vena cava.
- **Periumbilical Arterial Anastomoses:** A rich vascular plexus exists between the peritoneum and the posterior rectus sheath beneath the umbilicus.[1] This plexus incorporates contributions from vessels coursing through the median umbilical ligament as well as those running along the ligamentum teres hepaticum, a fibrous cord that is the remnant left umbilical vein.
- **Periumbilical Venous Anastomoses:** The superior and inferior epigastric veins anastomose with veins in the falciform ligament.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; in more cranial regions, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep surface. Figure 13-20 exposes the inferior epigastric arteries and veins as they ascend the abdomen.

Three distinct sources contribute to the subumbilical vascular plexus: 1) Deep inferior epigastric arteries and veins, 2) Vessels following the ligamentum teres hepaticum, and 3) Vessels associated with the median umbilical ligament. Most of the arterial vascular supply to this region originates from the deep inferior epigastric arteries via small and large perforating vessels. These perforators course toward the midline from the rectus muscle along premuscular, intramuscular, and postmuscular pathways. The umbilical skin receives blood from the subdermal plexus along with a large number of cutaneous perforators that enter the skin at the rectus abdominis muscle's tendinous intersections.

Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[3] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[4]

The valveless epigastric veins serve as collateral drainage routes for abdominopelvic blood. In the event of vena caval obstruction or ligation, the epigastric veins ferry venous blood craniad across the abdominal wall and into the internal thoracic, subclavian and brachiocephalic veins. From there, it empties into the superior vena cava. In cases of portal hypertension, blood shuns from the portal system to the systemic venous system. Venous expansions on the abdominal wall delineate superficial collateral drainage alternatives when pathology deters drainage through deeper routes.[5]

Extreme dilation of periumbilical veins results in the recognizable "caput medusae". Circulation through the portal system as it courses through the liver may be reduced or obstructed from either hepatic disease or physical obstruction (e.g., tumor) blocking flow. In these instances, blood from the gastrointestinal tract can still make its way back to the right side of the heart, via the inferior vena cava, by a number of collateral routes. Blood can flow in this reverse direction because the portal veins and its tributaries are valveless.

Unusual collateral vessel connections in vena caval obstruction have shown that elaborate, myriad combinations are possible, including the following pathways: caval-superficial-umbilical-portal, caval-mammary-phrenic-hepatic capsule-portal, cavalmesenteric-portal, caval-renal-portal, caval-retroperitoneal-portal, and intrahepatic cavoportal.[6]

Indications and Potential Point Combinations

- **Periumbilical pain:** CV 7, CV 9, KI 16, ST 25.
- **Abdominal distension:** CV 7, CV 12, ST 25, ST 36, BL 25.

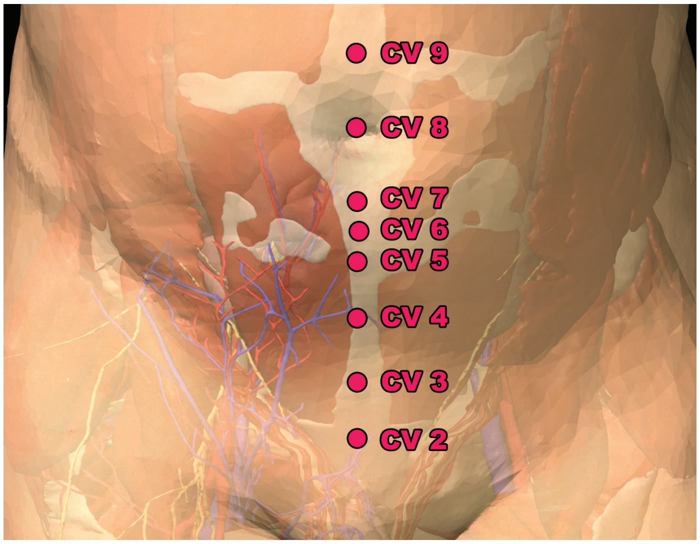

Figure 13-21. Compare the location of periumbilical vessels in this image to their appearance in the previous figure. Imagine the vessels on the individual's left side as well, not shown, reaching toward CV 4 through CV 8. The anatomy thus bespeaks the points' potential influence on circulation through the caudal abdomen.

Evidence-Based Applications

- Moxibustion at CV 7, CV 5, CV 4, CV 3, GV 4, BL 18, BL 22, BL 23, and BL 52 increased **pregnancy** rate after embryo implantation failed.[7]

In the center of the umbilicus.

Needling is contraindicated at this point. Treatment usually consists of moxibustion, though laser therapy offers a smoke-free alternative.

Connective Tissues

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Median umbilical ligament:** This remnant of the urachus had at one time joined the apex of the fetal bladder to the umbilicus. The median umbilical ligament represents the embryologic remnant of the cloaca and allantois. Coursing from the urinary bladder to the umbilicus, the median umbilical fold covers the median umbilical ligament.
- **Falciform ligament:** This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. It comprises two mesothelial layers of peritoneum filled with extraperitoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[4] Venous blood from the falciform drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

Clinical Relevance: Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[5] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[6] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullne ss, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[7] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[8] Sepsis involving the ligament can arise from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is showing increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI and CV points between the sternum and umbilicus should not enter the abdomen nor invade the falciform ligament. Rather, the benefit of local needling should remain superficial to avoid the ligament but at least indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T10):** Supplies the anterior abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Nerves supplying CV 8 overlap with activities of other points in the caudal abdomen; namely, they neuromodulate caudal abdominal visceral activities pertaining mostly to digestive functions. The heat of moxibustion at CV 8 may neuromodulate the enteric nervous system within the walls of the intestine deep to the point. If peristalsis in local loops improved, waves of nerve signals may promulgate throughout the small intestine and restore healthful bowel function. Figure 13-23 reveals the proximity of ileal loops to the falciform ligament and CV 8.

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area cranial to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the ventrolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as

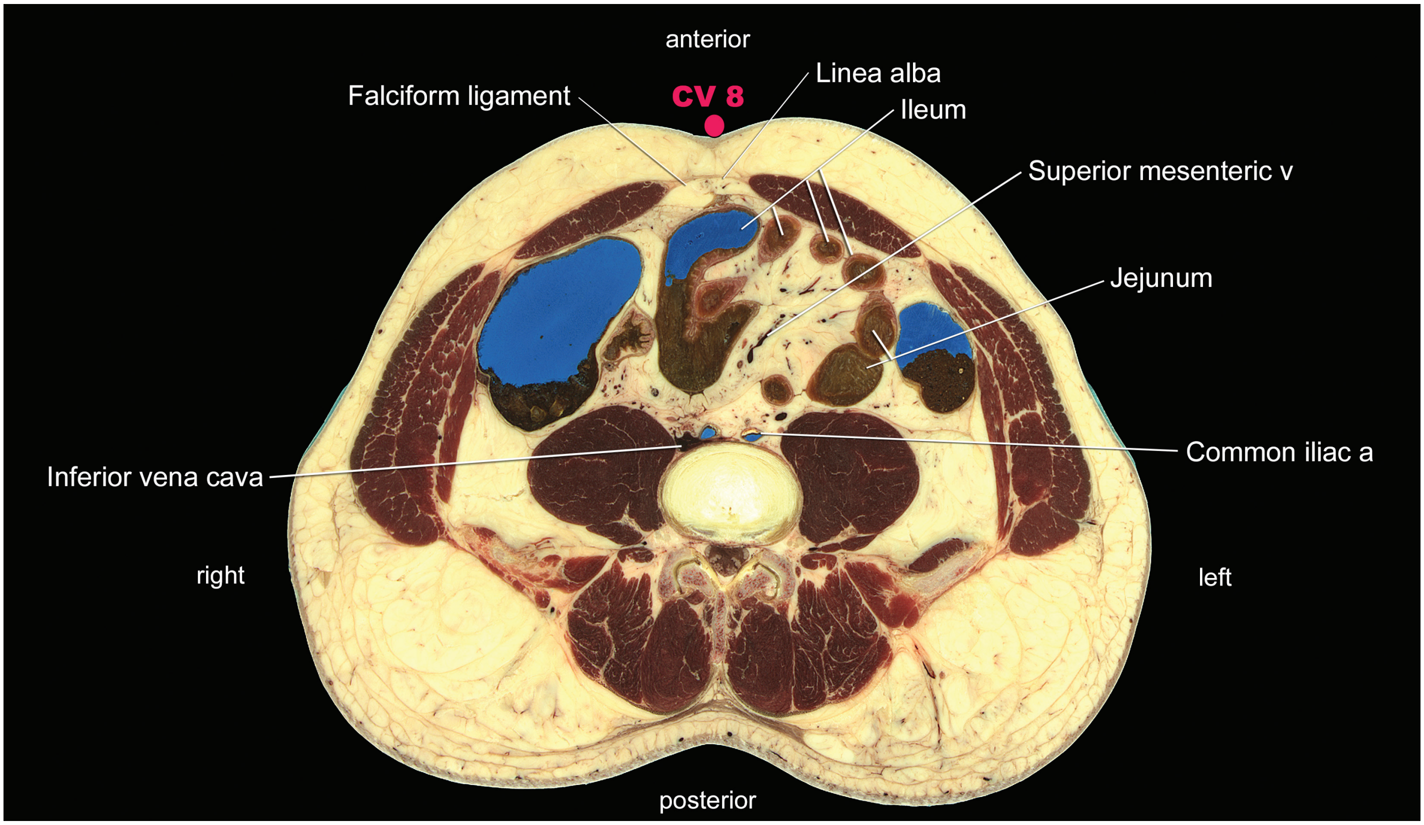

Figure 13-23. The names "Spirit Gate", "Spirit Palace", and "Spirit Gate Tower" for CV 8 connote the connection between the umbilicus and one's mother. Ancient Chinese philosophy held that the umbilicus served as a gate through which the spirit entered and left the body. In ancient times, the quasi-spiritual nature of the point may have made it "off limits" to needle. Or, perhaps then as now, needling the often-unclean umbilicus may have introduced harmful bacteria into falciform ligament tissue and pose the possibility of developing an abscess or sepsis. Note that, in contrast to horizontal sections cranial and caudal to this level, the main organs present in this plane pertain to digestion. No wonder that the main indication for moxibustion at CV 8 is diarrhea!

collateral routes for abdominopelvic blood return to the heart. These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the internal thoracic, subclavian and brachiocephalic veins, and from there, into the superior vena cava.

Periumbilical Arterial Anastomoses: A rich vascular plexus exists between the peritoneum and the posterior rectus sheath beneath the umbilicus.[1] This plexus incorporates contributions from vessels coursing through the median umbilical ligament as well as those running along the ligamentum teres hepaticum, a fibrous cord that is the remnant left umbilical vein.

Periumbilical Venous Anastomoses: The superior and inferior epigastric veins anastomose with veins in the falciform ligament.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; in more cranial regions, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep surface. Figure 13-20 exposes the inferior epigastric arteries and veins as they ascend the abdomen.

Three distinct sources contribute to the subumbilical vascular plexus: 1) Deep inferior epigastric arteries and veins, 2) Vessels following the ligamentum teres hepaticum, and 3) Vessels associated with the median umbilical ligament. Most of the arterial vascular supply to this region originates from the deep inferior epigastric arteries via small and large perforating vessels. These perforators course toward the midline from the rectus muscle along premuscular, intramuscular, and postmuscular pathways. The umbilical skin receives blood from the subdermal plexus along with a large number of cutaneous perforators that enter the skin at the rectus abdominis muscle's tendinous intersections.

The valveless epigastric veins serve as collateral drainage routes for abdominopelvic blood. In the event of vena caval obstruction or ligation, the epigastric veins ferry venous blood craniad across the abdominal wall and into the internal thoracic, subclavian and brachiocephalic veins. From there, it empties into the superior vena cava. In cases of portal hypertension, blood shuns from the portal system to the systemic venous system. Venous expansions on the abdominal wall delineate superficial collateral drainage alternatives when pathology deters drainage through deeper routes.[9]

Extreme dilation of periumbilical veins results in the characteristic "caput medusae". Circulation through the portal system as it courses through the liver may be reduced or obstructed from either hepatic disease or physical obstruction (e.g., tumor) blocking flow. In these instances, blood from the gastrointestinal tract can still make its way back to the right side of the heart, via the inferior vena cava, by a number of collateral routes. Blood can flow in this reverse direction because the portal veins and its tributaries are valveless.

Unusual collateral vessel connections in vena caval obstruction have shown that elaborate, myriad combinations are possible, including the following pathways: caval-superficial-umbilical-portal, caval-mammary-phrenic-hepatic capsule-portal, cavalmesenteric-portal, caval-renal-portal, caval-retroperitoneal-portal, and intrahepatic cavoportal.[10]

The anatomical layout of vessels around the umbilicus becomes of heightened importance during body contouring procedures such as abdominoplasty.[11] The venous drainage of the abdominal wall is even more variable than the arterial network, accentuating the risk of insufficient circulatory recovery of blood supply and drainage after abdominoplasty and transverse rectus abdominis myocutaneous (TRAM) flap reconstructions.

Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues.

Indications and Potential Point Combinations

- **Diarrhea:** Moxa at CV 8.

Evidence-Based Applications

- Moxa on CV 8 increased serum interleukin (IL)-2 and IL-12 levels, as well as **NK cell activity** in mice with transplanted tumors.[2]
- External application of the herbal mixture Huweigo to CV 8 for thirty days resulted in relief of **stomach pain**.[3]

CV 9

Shui Fen "Water Separation" "Water Divide"

On the ventral midline, 1 cun cranial to the umbilicus, 7 cun below the xiphisternal synchondrosis. Figure 13-24 illustrates the 8 cun count between the umbilicus and the xiphisternal junction.

Connective Tissues

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Median umbilical ligament:** This remnant of the urachus had at one time joined the apex of the fetal bladder to the umbilicus. The median umbilical ligament represents the embryologic remnant of the cloaca and allantois. Coursing from the urinary bladder to the umbilicus, the median umbilical fold covers the median umbilical ligament.
- **Falciform ligament:** This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. It comprises two mesothelial layers of peritoneum filled with extraperitoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[2] Venous blood from the falciform drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

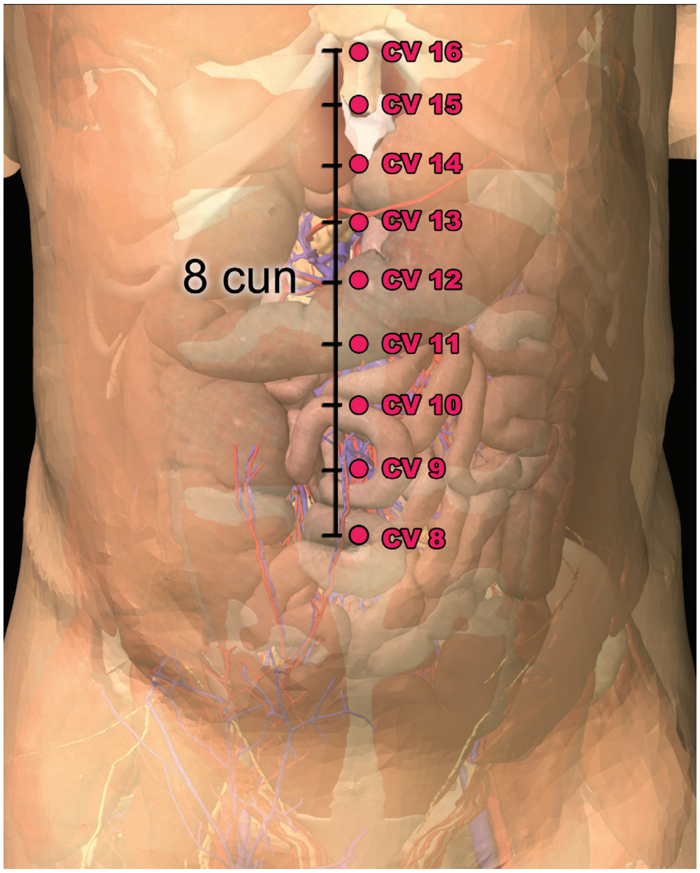

Figure 13-24. The name for CV 9, "Water Divide", refers to the activities of digestion and water absorption taking place in the small intestine, deep to the point.

Clinical Relevance: Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[3] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[4] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[5] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[6] Sepsis involving the ligament may develop from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is occurring with increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI and CV points between the sternum and umbilicus should not enter the abdomen nor invade the falciform ligament. Rather, the benefit of local needling should remain superficial to avoid the ligament but at least indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

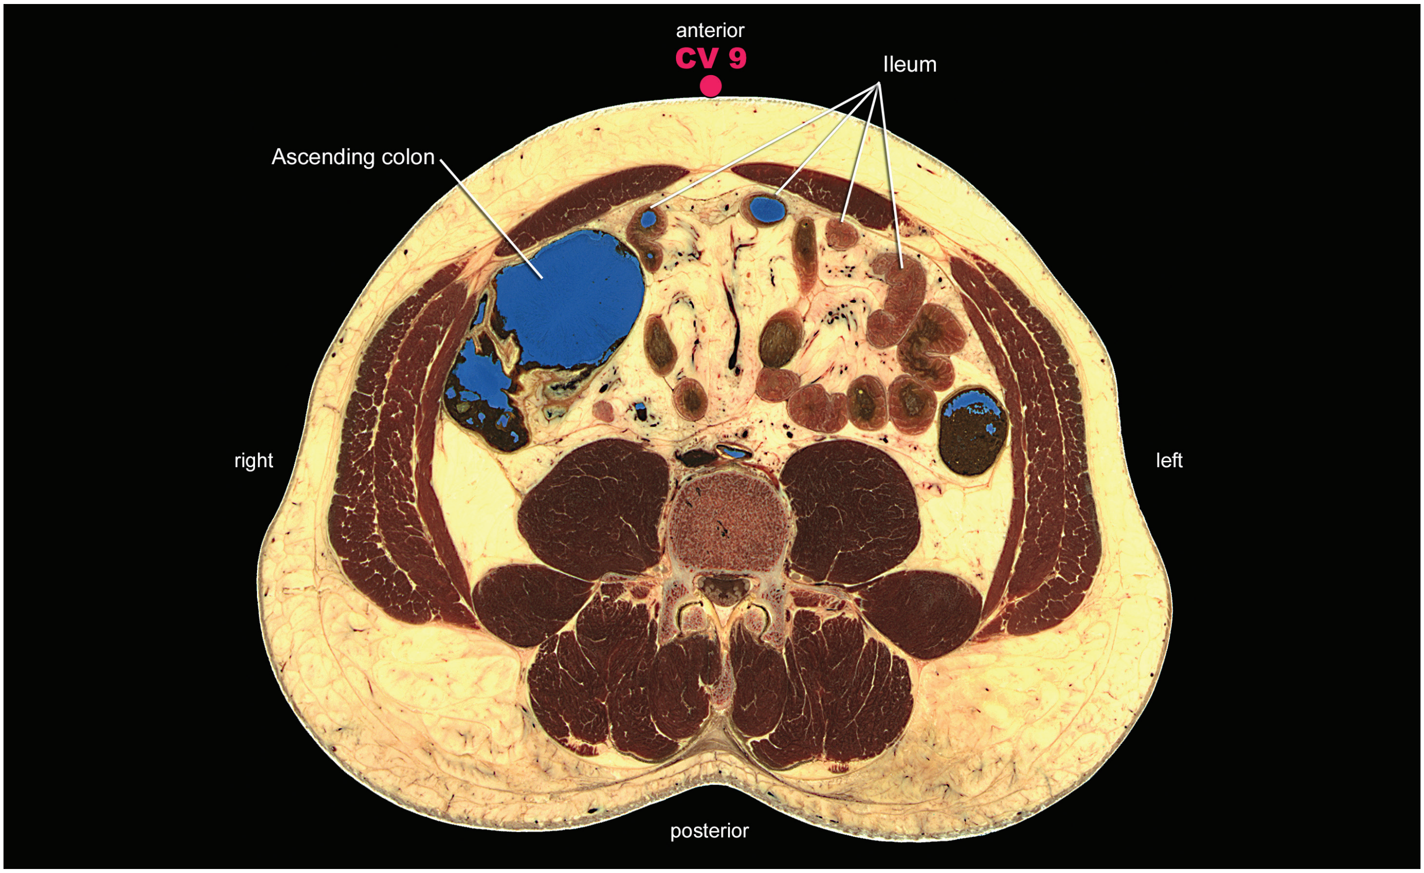

Figure 13-25. The loops of bowel and associated mesentery in this cross-section set the stage for one to consider how to neuromodulate digestive function by means of cutaneovisceral reflexes between CV 9 and organs supplied by the T9 (+/-) spinal cord segments.

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T9):** Supplies the anterior abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Nerves supplying CV 9 overlap with activities of other points in the mid-abdomen; namely, they neuromodulate visceral activities pertaining mostly to digestive functions.

Vessels

- **Superior superficial epigastric artery:** Supplies the subcutaneous tissue and skin above the umbilicus. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior superficial epigastric artery.

- **Superior deep epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.

- **Superior superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial inferior epigastric vein is a tributary of the great saphenous vein while the superior epigastric vein carries deoxygenated blood and drains into the internal thoracic vein. The superior and inferior superficial epigastric vessels anastomose at the level of the umbilicus.

- **Superior deep epigastric vein:** The superior epigastric vein, like its superficial counterpart, empties into the internal thoracic vein. Valves in the superior deep epigastric veins direct blood flow craniad, while those in the inferior group send blood caudad.[7]

- **Note about the periumbilical arterial anastomoses:** A rich vascular plexus lies beneath the umbilicus, between the peritoneum and the posterior rectus sheath.[1] This plexus incorporates a network of vessels arriving via the median umbilical ligament and the ligamentum teres hepaticum, a fibrous, cordlike remnant of the left umbilical vein. Vessels from both sides of the midline communicate with the anastomoses. Three sources contribute to the subumbilical vascular plexus: the deep inferior epigastric arteries (via small and large perforating vessels) and the arteries in the ligamentum teres hepaticum and the median umbilical ligament.

- **Note about the periumbilical venous anastomoses:** The superior and inferior epigastric veins anastomose with veins in the falciform ligament to form the periumbilical venous anastomoses. Excessive dilation ("caput medusae") of the periumbilical veins occurs as a consequence of portal hypertension, secondary to liver disease or obstruction.

Clinical Relevance: The anatomical layout of vessels around the umbilicus becomes of heightened importance during body contouring procedures such as abdominoplasty.[8] The venous drainage of the abdominal wall is even more variable than the arterial network, accentuating the risk of insufficient circulatory recovery of blood supply and drainage after abdominoplasty and transverse rectus abdominis myocutaneous (TRAM) flap reconstructions. Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues.

Indications and Potential Point Combinations

- **Diarrhea, constipation:** CV 9, CV 12, ST 36, BL 25, GV 20.
- **Periumbilical pain:** CV 9, CV 7, LR 14, GB 24.
- **Ascites:** CV 9, CV 5, BL 23, ST 25, ST 36.

Evidence-Based Application

- Laser acupuncture with 0.25J per point thrice weekly for one month, applied to CV 9, SP 15, ST 25, ST 28, ST 40, and auricular points "stomach" and "hunger" reduced weight and body mass in patients with **"visceral postmenopausal obesity",** i.e., abdominal girth increase in older adults.[9]

CV 10

Xia Wan or Xia Guan "Lower Stomach Cavity" "Lower Stomach Duct" "Lower Venter"

On the ventral midline, 2 cun cranial to the umbilicus, 6 cun Caudal to the xiphisternal synchondrosis. To find CV 10, first find the midpoint between the xiphisternal junction at CV 16 and the umbilicus, or CV 8 (a distance of 8 cun). This takes you to CV 12. Next, locate CV 10 midway between CV 12 and CV 8. Refer to Figure 13-26 for point placement according to cun measurement.

Connective Tissues

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Falciform ligament:** A double layer of peritoneum, containing the ligamentum teres, paraumbilical veins, and fat. It courses from the umbilicus to the diaphragm at the tendinous portion of the abdominal aspect. The paraumbilical veins and the umbilical vein (which becomes vestigial in the adult to form the ligamentum teres) comprise an accessory portal system in communication with the systemic venous network.
- **Falciform ligament:** This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. It comprises two mesothelial layers of peritoneum filled with extraperitoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[2] Blood that travels in veins within the falciform ligament usually drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

In Cruveilhier-Baumgarten syndrome, blood makes its way once again through the umbilical vein to the paraumbilical veins and on toward the umbilicus. There, the veins anastomose with systemic abdominal veins to create portosystemic anastomosis.[3]

Clinical Relevance: When infection, herniation, developmental anomalies, or vascular compromise affect the falciform ligament, it can cause nebulous abdominal pain and a feeling of abdominal fullness or dyspepsia. The falciform ligament with its lymphatic and vascular anatomic complexity allows spread of infection, or blood from intraabdominal pathology to the abdominal and thoracic wall.

Metastatic spread of pancreatic adenocarcinoma along the gastrohepatic ligament to the falciform ligament and on to the umbilicus is called the "Sister Mary Joseph" nodule, a sign of subumbilical metastasis.

Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[4] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[5] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[6] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[7] Sepsis involving the ligament may develop from infection spreading by direct extension

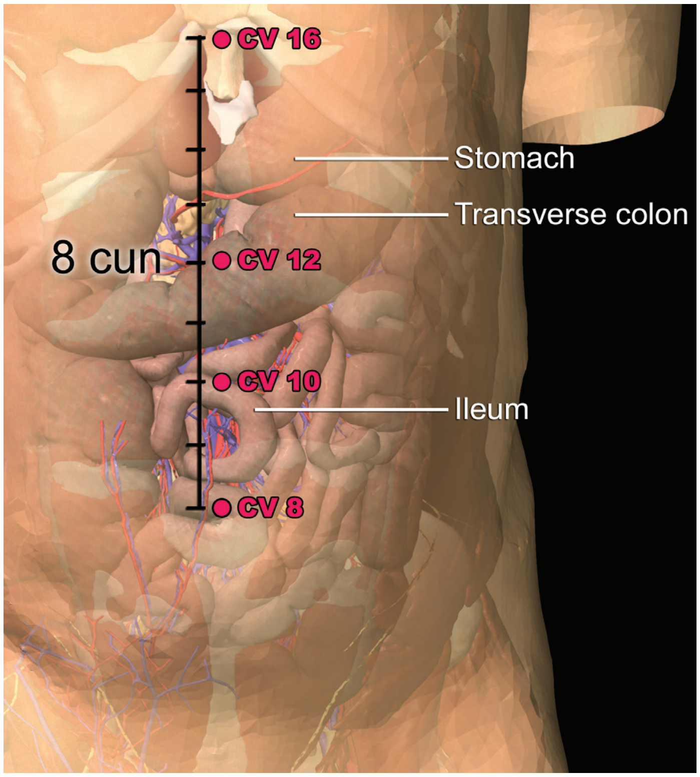

Figure 13-26. As shown by this image, CV 10 as the "Lower Stomach Cavity" and "Lower Stomach Duct" has less of an anatomical relationship with the stomach than the intestines. Likely, the name "lower stomach" referred to the intestinal tract rather than the stomach per se.

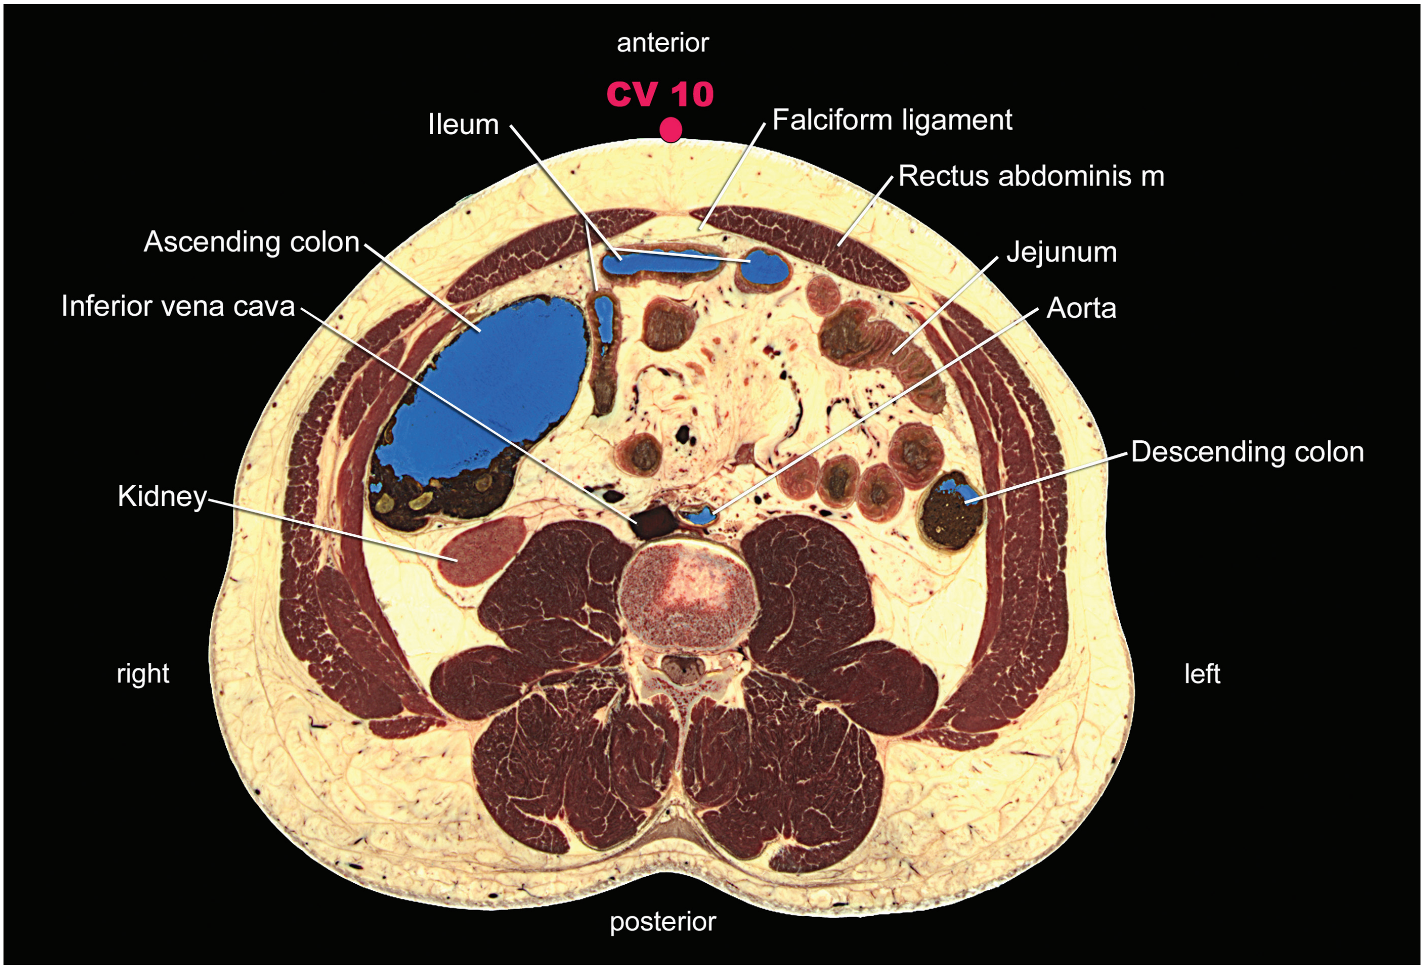

Figure 13-27. Acupressure at CV 10 can "disinhibit" the intestines and promote peristalsis. Try it on yourself to test its effectiveness.

or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is occurring with increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI and CV points between the sternum and umbilicus should neither enter the abdomen nor invade the falciform ligament. Rather, the benefit of local needling should remain superficial to avoid the ligament but at least indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T8, T9):** Supplies the anterior abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Acupuncture points in the cranial abdomen such as CV 10 have predominantly metabolic and digestive indications. This is because treatment at these sites influences nerves connected to spinal cord segments that help control these activities.

Vessels

- **Superior superficial epigastric artery:** Supplies the subcutaneous tissue and skin above the umbilicus. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior superficial epigastric artery.
- **Superior deep epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superior superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. The superior epigastric vein carries deoxygenated blood into the internal thoracic vein; as such, this vessel becomes a tributary of the internal thoracic vein. The superior and inferior superficial epigastric vessels anastomose at the level of the umbilicus.
- **Superior deep epigastric vein:** The superior epigastric vein, like its superficial counterpart, empties into the internal thoracic vein. Valves in the superior deep epigastric veins direct blood flow craniad, while those in the inferior group send blood caudad.[8]
- **Note about the periumbilical arterial anastomoses:** A rich vascular plexus lies beneath the umbilicus, between the

peritoneum and the posterior rectus sheath.[1] This plexus incorporates a network of vessels arriving via the median umbilical ligament and the ligamentum teres hepaticum, a fibrous, cordlike remnant of the left umbilical vein. Vessels from both sides of the midline communicate with the anastomoses. Three sources contribute to the subumbilical vascular plexus: the deep inferior epigastric arteries (via small and large perforating vessels) and the arteries in the ligamentum teres hepaticum and the median umbilical ligament.

- **Note about the periumbilical venous anastomoses:** The superior and inferior epigastric veins anastomose with veins in the falciform ligament to form the periumbilical venous anastomoses. Excessive dilation ("caput medusae") of the periumbilical veins occurs as a consequence of portal hypertension, secondary to liver disease or obstruction.

Clinical Relevance: The anatomical layout of vessels around the umbilicus becomes of heightened importance during body contouring procedures such as abdominoplasty.[9] The venous drainage of the abdominal wall is even more variable than the arterial network, accentuating the risk of insufficient circulatory recovery of blood supply and drainage after abdominoplasty and transverse rectus abdominis myocutaneous (TRAM) flap reconstructions.

Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues.

Indications and Potential Point Combinations

- **Painful or distended abdomen, diarrhea, vomiting, inappetance, poor digestion and assimilation, constipation:** CV 10, ST 25, ST 36, BL 25, BL 27, BL 10.
- **Insomnia:** CV 10, CV 12, CV 4, CV 6, KI 17, ST 24, ST 36, GV 20.

Evidence-Based Applications

- Acupuncture at CV 10, CV 12, CV 4, CV 6, II 18, ST 24, Xiafengshidian and Qipang (just below the umbilicus on either side of the midline separated by the width of the mouth) outperformed drug treatment for **insomnia** combined with sham acupuncture, according to a Chinese clinical trial.[1]

CV 12

Zhong Guan, Zhong Wan

"Middle Cavity", "Central Venter", or "Central Stomach Duct"

On the ventral midline, 4 cun cranial to the umbilicus, midway between the umbilicus and the xiphisternal synchondrosis. In the center of the epigastrium.

Connective Tissues

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Falciform ligament:** This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. It comprises two mesothelial layers of peritoneum filled with extra-peritoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[12] Blood that travels in veins within the falciform ligament usually drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

In Cruveilhier-Baumgarten syndrome, blood makes its way once again through the umbilical vein to the paraumbilical veins and on toward the umbilicus. There, the veins anastomose with systemic abdominal veins to create portosystemic anastomosis.[13]

Clinical Relevance: When infection, herniation, developmental anomalies, or vascular compromise affect the falciform ligament, it can cause nebulous abdominal pain and a feeling of abdominal fullness or dyspepsia. The falciform ligament with its lymphatic and vascular anatomic complexity allows spread of infection, or blood from intraabdominal pathology to the abdominal and thoracic wall.

Metastastic spread of pancreatic adenocarcinoma along the gastrohepatic ligament to the falciform ligament and on to the umbilicus is called the "Sister Mary Joseph" nodule, a sign of subumbilical metastasis.

Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[14] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[15] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[16] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[17] Sepsis involving the ligament may develop from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is occurring with increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI and CV points between the sternum and umbilicus should neither enter the abdomen nor invade the falciform ligament. Rather, the benefit of local needling should remain superficial to avoid the ligament but at least indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

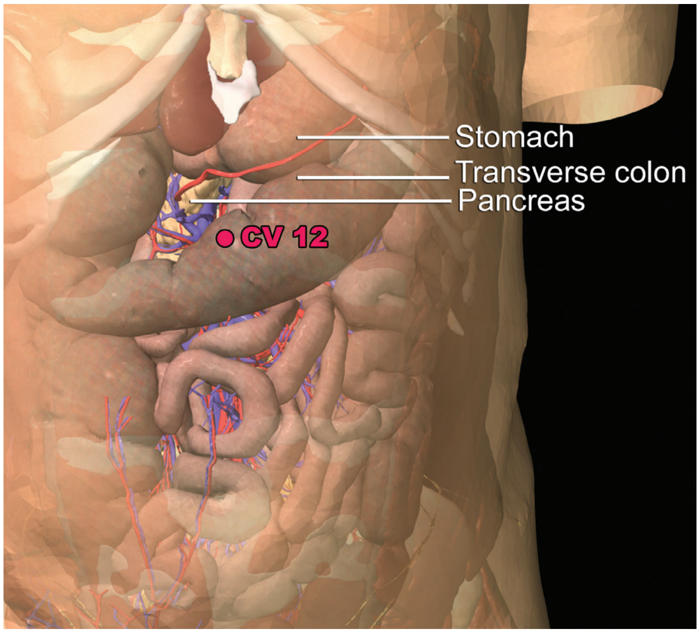

Figure 13-30. CV 12, as the "Central Stomach Duct" and major point in the "Middle Cavity" also serves as the Front Mu point for the stomach organ, influencing a host of digestive activities.

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T7, T8):** Supplies the anterior abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Acupuncture points in the cranial abdomen such as CV 12 have predominantly metabolic and digestive applications. This is because treatment at these sites influences nerves connected to spinal cord segments that help control these activities.

Vessels

- **Superior superficial epigastric artery:** Supplies the subcutaneous tissue and skin above the umbilicus. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior superficial epigastric artery.
- **Superior deep epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superior superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. The superior epigastric vein carries deoxygenated blood into the internal thoracic vein; as such, this vessel becomes a tributary of the internal thoracic vein. The superior and inferior superficial epigastric vessels anastomose at the level of the umbilicus.
- **Superior deep epigastric vein:** The superior epigastric vein, like its superficial counterpart, empties into the internal thoracic vein. Valves in the superior deep epigastric veins direct blood flow craniad, while those in the inferior group send blood caudad.[18]
- **Note about the periumbilical arterial anastomoses:** A rich vascular plexus lies beneath the umbilicus, between the peritoneum and the posterior rectus sheath. This plexus incorporates a network of vessels arriving via the median umbilical ligament and the ligamentum teres hepaticum, a fibrous, cordlike remnant of the left umbilical vein. Vessels from both sides of the midline communicate with the anastomoses. Three sources contribute to the subumbilical vascular plexus: the deep inferior epigastric arteries (via small and large perforating vessels) and the arteries in the ligamentum teres hepaticum and the median umbilical ligament.
- **Note about the periumbilical venous anastomoses:** The superior and inferior epigastric veins anastomose with veins in the falciform ligament to form the periumbilical venous anastomoses. Excessive dilation ("caput medusae") of the periumbilical veins occurs as a consequence of portal hypertension, secondary to liver disease or obstruction. Blunt trauma to the abdomen may also cause vena caval blockage, leading to venous engorgement from pubis (CV 2) to xiphoid (CV 16) and as far lateral as LR 13.[19]

Clinical Relevance: The anatomical layout of vessels around the umbilicus becomes of heightened importance during body contouring procedures such as abdominoplasty.[20] The venous drainage of the abdominal wall is even more variable than the arterial network, accentuating the risk of insufficient circulatory recovery of blood supply and drainage after abdominoplasty and transverse rectus abdominis myocutaneous (TRAM) flap reconstructions.

Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues.

Avoid needling engorged vessels on the abdominal wall.

Indications and Potential Point Combinations

- **Most abdominal and digestive problems, including stomach pain, vomiting, gastritis, stomach or duodenal ulcers, abdominal distension, diarrhea, anorexia, and retention of food in stomach:** CV 12, PC 6, ST 36, SP 6, BL 21, Yintang (GV 24.5).
- **Feeling "scattered" or agitated:** CV 12, PC 6, LR 3, LI 4, GV 20.

Evidence-Based Applications

- Regarding the effects of acupuncture on canine gastric motility using ST 36, ST 40, ST 41, ST 42, ST 45, BL 12, or CV 12, only stimulation of ST 36 or BL 21 promoted gastric motility, whereas **motility decreased** with CV 12 stimulation. No significant changes in motility occurred after acupuncture at ST 40, ST 41, ST 42, or ST 45.[1]
- Moxibustion (using Artemisia vulgaris) at CV 12, ST 25, and ST 36 was effective in **preventing acute gastric lesions** induced by indomethacin in rats.[2]
- Acupuncture at CV 12, ST 36, PC 6, SP 4, BL 20, and BL 21, with either the adjunct points LI 11, GB 34, and LR 3 or CV 6, CV 4, and SP 6 improved gastric emptying in a case series of patients with **diabetic gastroparesis**.[3]
- Acupuncture at ST 36, CV 12, and PC 6 served as an effective short- and medium-term treatment for **chronic idiopathic dyspepsia,** with fewer adverse effects and longer effectiveness than treatment with the prokinetic agent, domperidone.[4]
- Acupuncture at LI 4, ST 36, PC 6, LR 3, CV 12, CV 17, and CV 22 successfully treated **sleep-related laryngospasm from gastroesophageal reflux,** refractory to current medical treatment; results were maintained at a 1-year follow-up assessment, and no evidence of reflux was detected upon repeated upper gastrointestinal study.[5]
- Electroacupuncture at CV 12, ST 36, PC 6, LR 3, and SP 4 daily for six weeks, in conjunction with zhizhukuanzhong capsules (a Chinese herbal formula) improved quality of life and reduced intraesophageal acid and bile reflux in patients with confirmed **gastroesophageal reflux disease (GERD).**[21]
- Acupuncture at CV 12, ST 36, SP 6, and PC 6 once daily for one week for multiple courses over a six week period experienced significant alleviation of symptoms and less intraesophageal acid and bile reflux. Results were not significantly different from patients who received omeprazole and mosapride.[22]
- Electroacupuncture (EA) at CV 4 and CV 12 in diabetic rats induced secretion of endogenous β-endorphin; this **reduced**

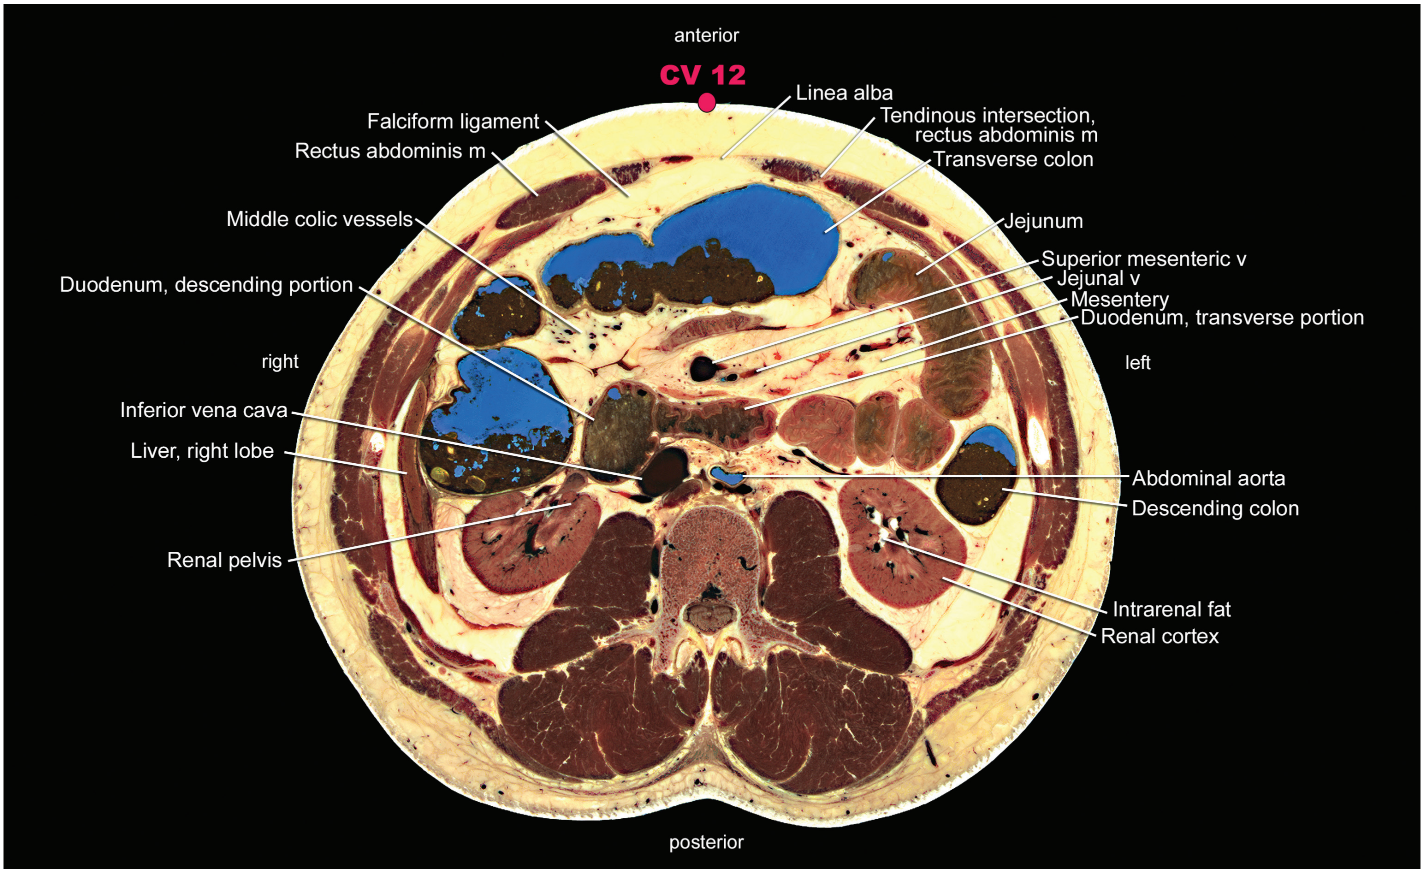

Figure 13-31. Early Chinese acupuncturists viewed CV 12 as an influential point for bowels, an impression this cross-section reinforces. This image also shows the falciform ligament arcing toward the liver, true to its name of "sickle-shaped".

plasma glucose concentration in an insulin-dependent manner.[6]

- EA at CV 12 caused beta-endorphin release from the adrenal gland, which subsequently **lowered plasma glucose** in an insulin-dependent manner.[7]
- Bee venom stimulation of CV 12 produced **visceral antinociception** in mice that was associated with α2-adrenoceptors, but not naloxone-sensitive opioid receptors.[8]
- Acupuncture at CV 6, CV 12, CV 17, ST 36, and SP 10 conferred protective effects on cognitive impairments caused by multiinfarction dementia in rats, suggesting it may benefit patients with **vascular dementia.**[9]
- Acupuncture at LR 3, SP 6, ST 36, CV 12, LI 4, PC 6, GB 20, GB 14, Taiyang, and GV 20 provided greater effectiveness in prophylaxis of **migraine** compared to flunarizine.[10]
- Acupuncture at LU 9, ST 36, ST 40, SP 1, SI 3, BL 15, LR 3, CV 12, and CV 14 induced long-lasting reductions in attacks of primary **Raynaud's syndrome,** demonstrated effectiveness comparable to nifedipine, and did so without adverse effects.[11]

CV 13

Shang Guan, Shang Wan

"Upper Cavity" "Upper Stomach Duct" "Upper Venter"

On the ventral midline, 3 cun caudal to the xiphisternal synchondrosis, or 5 cun cranial to the umbilicus.

Compare the locations of CV 13, the "Upper Venter" to CV 12, the "Central Venter", and CV 10, the "Lower Venter" in Figure 13-32.

Connective Tissues

- **Linea alba:** The linea alba arises from the anterior and posterior layers of the rectus sheath, which interlace in the anterior midline. The rectus sheath embodies the strong fibrous compartment that incompletely encloses the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.
- **Transversalis fascia:** This firm fascial sheet lines most of the abdominal wall, covers the deep surface of the transverse abdominal muscle and its aponeurosis, and is contiguous with and deep to the linea alba.
- **Falciform ligament:** This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. It comprises two mesothelial layers of peritoneum filled with extra-peritoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[3] Blood that travels in veins within the falciform ligament usually drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

In Cruveilhier-Baumgarten syndrome, blood makes its way once again through the umbilical vein to the paraumbilical veins and on toward the umbilicus. There, the veins anastomose with systemic abdominal veins to create portosystemic anastomosis.[4]

Clinical Relevance: When infection, herniation, developmental anomalies, or vascular compromise affect the falciform ligament, it can cause nebulous abdominal pain and a feeling of abdominal fullness or dyspepsia. The falciform ligament with its lymphatic and vascular anatomic complexity allows spread of infection, or blood from intraabdominal pathology to the abdominal and thoracic wall.

Metastastic spread of pancreatic adenocarcinoma along the gastrohepatic ligament to the falciform ligament and on to the umbilicus is called the "Sister Mary Joseph" nodule, a sign of subumbilical metastasis.

Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[5] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[6] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[7] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[8] Sepsis involving the ligament may develop from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is occurring with increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI and CV points between the sternum and umbilicus should neither enter the abdomen nor invade the falciform ligament. Rather, the benefit of local needling should

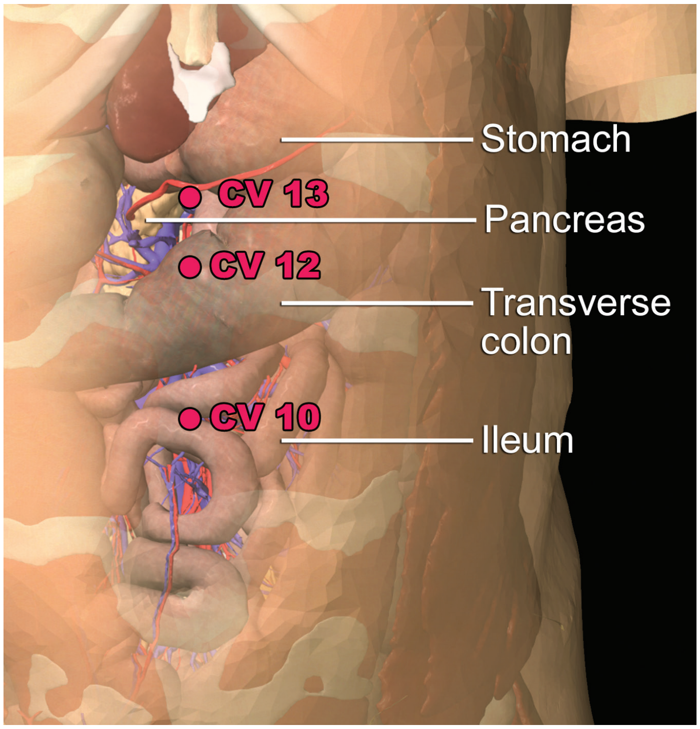

Figure 13-32. The upper, middle, and lower "venters", alternate titles for CV 13, CV 12, and CV 10, respectively, may refer to the stomach, transverse colon, and ileum, as shown here.

Figure 13-33. The cornucopia of organs in this cranial abdominal cross-section highlights the potential for diverse somatovisceral reflex potential of CV 13. While the stomach has not appeared in the same plane as any of the "stomach duct" or "venter" sites (i.e., CV 13, CV 12, and CV 10), this cross section exposes the relationships of several other digestive structures, including the duodenum, common bile duct, pancreas, jejunum, and transverse colon with CV 13. The vena cava, singular vessel affiliated with the CV channel, displays its linkage with the renal vein.

remain superficial to avoid the ligament but at least indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T7, T8):** Supplies the anterior abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Acupuncture points in the cranial abdomen such as CV 13 have predominantly metabolic and digestive applications. This is because treatment at these sites influences nerves connected to spinal cord segments that help control these activities.

Vessels

- **Superior superficial epigastric artery:** Supplies the subcutaneous tissue and skin above the umbilicus. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior superficial epigastric artery.
- **Superior deep epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superior superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. The superior epigastric vein carries deoxygenated blood into the internal thoracic vein; as such, this vessel becomes a tributary of the internal thoracic vein. The superior and inferior superficial epigastric vessels anastomose at the level of the umbilicus.
- **Superior deep epigastric vein:** The superior epigastric vein, like its superficial counterpart, empties into the internal thoracic vein. Valves in the superior deep epigastric veins direct blood flow craniad, while those in the inferior group send blood caudad.[9]
- **Note about the periumbilical arterial anastomoses:** A rich vascular plexus lies beneath the umbilicus, between the peritoneum and the posterior rectus sheath. This plexus incorporates a network of vessels arriving via the median umbilical ligament and the ligamentum teres hepaticum, a fibrous, cordlike remnant of the left umbilical vein. Vessels from both sides of the midline communicate with the anastomoses. Three sources contribute to the subumbilical vascular plexus: the deep inferior epigastric arteries (via small and large perforating vessels) and the arteries in the ligamentum teres hepaticum and the median umbilical ligament.[10]
- **Note about the periumbilical venous anastomoses:** The superior and inferior epigastric veins anastomose with veins in

the falciform ligament to form the periumbilical venous anastomoses. Excessive dilation ("caput medusae") of the periumbilical veins occurs as a consequence of portal hypertension, secondary to liver disease or obstruction. Blunt trauma to the abdomen may also cause vena caval blockage, leading to venous engorgement from pubis (CV 2) to xiphoid (CV 16) and as far lateral as LR 13.

Clinical Relevance: The anatomical layout of vessels around the umbilicus becomes of heightened importance during body contouring procedures such as abdominoplasty.[11] The venous drainage of the abdominal wall is even more variable than the arterial network, accentuating the risk of insufficient circulatory recovery of blood supply and drainage after abdominoplasty and transverse rectus abdominis myocutaneous (TRAM) flap reconstructions.

Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues.

Avoid needling engorged vessels on the abdominal wall.

Indications and Potential Point Combinations

- **Gastritis, stomach pain, abdominal distension, nausea, vomiting:** CV 13, ST 25, ST 36, PC 6, BL 20, BL 21.
- **Hiccoughs (hiccups):** CV 13, CV 14, CV 22, KI 21, BL 17.

Acupressure to these points while inhaling slowly and deeply can also counteract hiccoughs, as an alternative to needling them.

- **Cholecystitis:** CV 13, GB 24, LR 14, LR 3, BL 18, BL 19, ST 36, GB 34.
- **Seizures, agitation:** CV 13, HT 7, PC 5, ST 40, LR 2, GV 20.

Evidence-Based Applications

- Transcutaneous electrical acupuncture point stimulation applied to PC 6 and CV 13 prevented **postoperative vomiting** following pediatric tonsillectomy as well as ondansetron, and with fewer side effects.[1]
- Acupuncture at PC 6 and CV 13 was as effective alternative to ondansetron for the prevention of **postoperative vomiting in children** undergoing dental surgery with general anesthesia.[2]

Acupuncture at KI and CV points between the sternum and umbilicus should neither enter the abdomen nor invade the falciform ligament. Rather, the benefit of local needling should remain superficial to avoid the ligament but at least indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T7):** Supplies the anterior abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Acupuncture points in the cranial abdomen such as CV 14 have predominantly metabolic and digestive applications. This is because treatment at these sites influences nerves connected to spinal cord segments that help control these activities. That said, however, the classification of CV 14 as the Front Mu point for the heart suggests some crossover effects for organs of the caudal thorax.

Gallstone pain sometimes appears at CV 14.[10] Pain may also refer to GB 24, GV 6, and GV 11.

Vessels

- **Superior superficial epigastric artery:** Supplies the subcutaneous tissue and skin above the umbilicus. A direct continuation of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior superficial epigastric artery.
- **Superior deep epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superior superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. The superior epigastric vein carries deoxygenated blood into the internal thoracic vein; as such, this vessel becomes a tributary of the internal thoracic vein. The superior and inferior superficial epigastric vessels anastomose at the level of the umbilicus.
- **Superior deep epigastric vein:** The superior epigastric vein, like its superficial counterpart, empties into the internal thoracic vein. Valves in the superior deep epigastric veins direct blood flow craniad, while those in the inferior group send blood caudad.[11]
- **Note about the periumbilical arterial anastomoses:** A rich vascular plexus lies beneath the umbilicus, between the peritoneum and the posterior rectus sheath. This plexus incorporates a network of vessels arriving via the median umbilical ligament and the ligamentum teres hepaticum, a fibrous, cordlike remnant of the left umbilical vein. Vessels from both sides of the midline communicate with the anastomoses. Three sources contribute to the subumbilical vascular plexus: the deep inferior epigastric arteries (via small and large perforating vessels) and the arteries in the ligamentum teres hepaticum and the median umbilical ligament.
- **Note about the periumbilical venous anastomoses:** The superior and inferior epigastric veins anastomose with veins in the falciform ligament to form the periumbilical venous anastomoses. Excessive dilation ("caput medusae") of the periumbilical veins occurs as a consequence of portal hypertension, secondary to liver disease or obstruction. Blunt trauma to the abdomen may also cause vena caval blockage, leading to venous engorgement from pubis (CV 2) to xiphoid (CV 16) and as far lateral as LR 13.[12]

Clinical Relevance: Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues in the cranial thorax.

Avoid needling engorged vessels on the abdominal wall.

Indications and Potential Point Combinations

- **Lack of will or motivation:** CV 14, ST 25, CV 6, BL 23, LR 3, GV 24.5 (Yintang).
- **Anxiety, fear:** CV 14, BL 15, HT 7, PC 7, LR 3, GV 20.
- **Feeling of pain or fullness in the chest, palpitations:** CV 14, CV 17, PC 6, PC 7, BL 13, BL 14, BL 15, LR 2, LR 3.
- **Stomach pain, nausea, vomiting, gastric reflux, esophageal motility disorders, acid regurgitation:** CV 14, CV 15, CV 22, ST 36, BL 10, BL 17, BL 18.
- **Stomach problems of emotional origin:** CV 14, CV 12, KI 21, ST 36, Yintang.

Evidence-Based Applications

- Following **acute myocardial infarction,** patients receiving acupuncture at CV 14, CV 17, ST 36, PC 6, and SP 6 demonstrated the following changes: reduced blood viscosity and myocardial oxygen consumption, improved microcirculation and left ventricular function, improved collateral circulation, and reduced the area of infarction.[1]

Figure 13-35. The relationship of CV 14 to the heart may pertain more closely to the effects of neuromodulation of cranial abdominal organs such as the liver, adrenal gland, and pancreas, all of which participate in adaptation to stress.

- Laser acupuncture significantly outperformed sham laser for the treatment of **mild to moderate depression** with the following points: LR 8, LR 14, CV 14, CV 15, HT 7, SP 6, LI 4, and GV 20.[2]
- Laser acupuncture at CV 14, LR 14, LR 8, HT 7, and KI 3 reduced depressive symptoms in patients with **major depressive disorder** in a randomized, double-blind, placebo controlled trial.[13]
- Laser acupuncture applied to CV 14, LR 14, LR 8, and HT 7 stimulated, as a group, the **frontal-limbic-striatal brain regions,** through the patterns of neural activity differed slightly for each individual point.[14]
- Acupuncture at LU 9, ST 36, ST 40, SP 1, SI 3, BL 15, LR 3, CV 12, and CV 14 induced long-lasting reductions in attacks of primary **Raynaud's syndrome,** demonstrated effectiveness comparable to nifedipine, and did so without adverse effects.[3]

CV 15

Jiu Wei "Turtledove Tail"

On the ventral midline, 1 cun caudal to the xiphisternal synchondrosis, or 7 cun cranial to the umbilicus.

Connective Tissues

- **Falciform ligament:** This sickle-shaped ligament attaches the liver to the ventral body wall. An embryologic remnant of the ventral mesentery, the falciform ligament denotes the separation of the most caudal portion of the left liver lobe into medial and lateral segments. The ligament attaches to the deep surface of the rectus abdominis as far down as the umbilicus. It comprises two mesothelial layers of peritoneum filled with extra-peritoneal fat; the free edge houses the embryonic remnant of the ligamentum teres hepatis (obliterated left umbilical vein), muscular fibers, and paraumbilical veins. These vessels may re-open in patients with portal hypertension, as the congestion in the liver purses venous blood toward the abdominal wall and into previously dormant vascular pathways. The falciform ligament receives its blood supply from the left phrenic artery and a branch of the middle segment artery of the liver.[2] Blood that travels in veins within the falciform ligament usually drains into the left inferior phrenic vein. The paraumbilical veins together with the umbilical vein create an accessory portal system in communication with the systemic venous system. The inferior epigastric veins connect to the paraumbilical veins (of Burrow).

In Cruveilhier-Baumgarten syndrome, blood makes its way once again through the umbilical vein to the paraumbilical veins and on toward the umbilicus. There, the veins anastomose with systemic abdominal veins to create portosystemic anastomosis.[3]

Clinical Relevance: When infection, herniation, developmental anomalies, or vascular compromise affect the falciform ligament, it can cause nebulous abdominal pain and a feeling of abdominal fullness or dyspepsia. The falciform ligament with its lymphatic and vascular anatomic complexity allows spread of infection, or blood from intraabdominal pathology to the abdominal and thoracic wall.

Metastastic spread of pancreatic adenocarcinoma along the gastrohepatic ligament to the falciform ligament and on to the umbilicus is called the "Sister Mary Joseph" nodule, a sign of subumbilical metastasis.

Internal hernias, such as those involving the falciform ligament, can develop within defects in the ligament that begin as congenital defects or were acquired after trauma, pregnancy, or laparoscopic surgery.[4] During the latter, the placement of a laparoscopic trocar can tear a rent in the ligament. A congenital or acquired hernia in the ligament may trap, obstruct, or strangulate a loop of intestine.[5] Patients with disorders affecting the falciform ligament typically complain of severe abdominal pain in the cranial abdomen, possibly localized to the right upper quadrant. Cysts in the falciform give patients the perception of fullness, an abdominal mass, pain, or dyspepsia in the vicinity of the space-occupying lesion.

Falciform ligament abscess is another potential complication of laparoscopic surgery,[6] although gallbladder and hepatic pathology have also been determined as causative factors in abscess formation. Other pathology striking the structure includes inflammation after acute cholecystitis; ligament necrosis, and hematoma.[7] Sepsis involving the ligament may develop from infection spreading by direct extension or lymphatic spread. The extensive network connecting the falciform to other areas creates a complex vascular and lymphatic interchange through which infection can spread to and from, including the diaphragm, liver, retroperitoneum, and thoracoabdominal wall.

Hemorrhage is occurring with increased frequency of occurrence due to the rising number of patients receiving anticoagulant medication; bleeding may spread into the rectus sheath or remain within the ligament.

Acupuncture at KI and CV points between the sternum and umbilicus should neither enter the abdomen nor invade the falciform ligament. Rather, the benefit of local needling should remain superficial to avoid the ligament but at least indirectly influence tension in the tissue and local blood flow. Massage and laser therapy provide noninvasive alternative means of releasing the structure.

Nerves

- **Thoracoabdominal nerves (T7-T11, mainly T7):** Supplies the anterior abdominal muscles and the skin overlying them. Also supplies the periphery of the diaphragm.

Clinical Relevance: Acupuncture points in the cranial abdomen such as CV 15 may have both caudal thoracic and cranial abdominal applications, in that its position over the xiphoid process marks a zone of transition.

Vessels

- **Superior superficial epigastric artery:** Supplies the subcutaneous tissue and skin above the umbilicus. A direct continuation

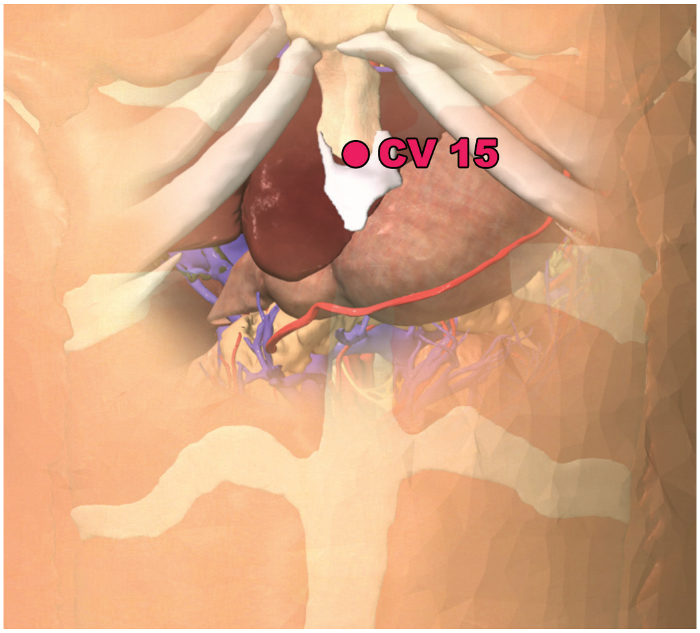

Figure 13-36. The xiphoid process resembles a "turtledove's tail", hence its descriptive name. To extend the metaphor, the sternum embodies the bird's back and the ribs, its wings.

Figure 13-37. Emotional disorders may cause tension and digestive disturbances in the central cranial abdomen, just caudal to the sternum. Here at the "pit" of the stomach, CV 15 relates closely to the pyloric sphincter, the so-called "pit". Cholecystokinin (CCK), a brain-gut peptide that regulates gastrointestinal function, inhibits gastric motility and emptying.[9] This neurotransmitter also mediates panic disorder, pain, and anxiety. As such, a somato-emotional connection between anxiety and visceral dysfunction manifests at CV 15.

of the internal thoracic artery, the superior epigastric artery descends within the rectus sheath, deep to the rectus abdominis muscle. It supplies the rectus abdominis muscle and the superior portion of the anterolateral abdominal wall. It anastomoses with the inferior superficial epigastric artery.

- **Superior deep epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superior superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. The superior epigastric vein carries deoxygenated blood into the internal thoracic vein; as such, this vessel becomes a tributary of the internal thoracic vein. The superior and inferior superficial epigastric vessels anastomose at the level of the umbilicus.
- **Superior deep epigastric vein:** The superior epigastric vein, like its superficial counterpart, empties into the internal thoracic vein. Valves in the superior deep epigastric veins direct blood flow craniad, while those in the inferior group send blood caudad.[8]

Clinical Relevance: Laser therapy and other physical medicine measures assist in the restoration of circulation and should be considered for wound healing issues in the cranial thorax.

Indications and Potential Point Combinations

- **Abdominal disorders, spastic discomfort, nausea and vomiting, gastric reflux:** CV 15, PC 6, ST 36, GV 20, LR 3, BL 18, BL 19.
- **Esophageal motility disorders:** CV 15, CV 14, CV 17, CV 22, ST 36, BL 16, GV 14.
- **Hiccoughs:** CV 15, CV 14, CV 22, BL 17. Acupressure at CV 14, KI 21.
- **Seizures:** CV 15, HT 7, ST 36, LR 2, LR 3, GV 20, Yintang.
- **Chest pain, palpitations, pericarditis:** CV 15, CV 14, BL 14, BL 15, PC 6, CV 17, ST 36, GV 20.
- **Mental disorders, agitation, depression:** CV 15, HT 7, Yintang, LR 3, LI 4, SP 6, GV 20.

Evidence-Based Applications

- Laser acupuncture significantly outperformed sham laser for the treatment of mild to moderate **depression** with the following points: LR 8, LR 14, CV 14, CV 15, HT 7, SP 6, LI 4, and GV 20.[1]

CV 16

Zhong Ting "Center Courtyard" "Central Palace"

On the ventral midline at the xiphisternal synchondrosis. Lands at or near the 5th intercostal space.

Joints

- **Xiphisternal synchondrosis (joint):** Indicates the inferior limit of the central thoracic cavity, the upper limit of the liver, the inferior border of the heart, and the central tendon of the diaphragm. The xiphisternal joint is usually level with the 9th thoracic vertebrae.[2]

Clinical Relevance: The xiphisternal angle has been dubbed the "angle of obesity", as a protruding abdomen causes the xiphoid process to point outward.[3]

Trauma surgeons may perform sub-xiphisternal pericardial windows in order to alleviate tamponade of the heart during aggressive surgical management of penetrating thoracic injuries.[4]

Patients with a history of complex surgery of the cranial abdomen may have undergone xiphoidectomy.[5] In this case, one would not locate CV 16 at the xiphisternal joint, but instead at the caudal end of the sternum.

Variant xiphoid morphology, as when it appears bifid, duplicated, or even trifurcated, may be mistaken on imaging as a xiphoid fracture.[6] These variations in the anatomy of the xiphoid, along with patent foramina in the sternum at more cranial CV points, could allow a needle to enter the thoracic cavity. Therefore, needle CV 16 to CV 21 carefully in order to avoid inadvertent organ puncture.

Should a patient present with a pulsatile bruise at the xiphisternal joint, DO NOT NEEDLE and have the patient seek IMMEDIATE emergency medical attention. A painless, pulsatile, sub-xiphisternal bruise may indicate ventricular free wall rupture.[7] The condition usually requires urgent surgery. While most left ventricular wall ruptures happen within the first week after myocardial infarction, delayed rupture can occur and become fatal if not addressed right away.

Foreign bodies or other causes of esophageal stimulation can cause pain in the central chest and mimic acute coronary syndrome.[8] For example, a coin lodged at the level of CV 16 can induce angina-like symptoms and electrocardiographic changes by means of neural reflexes between the esophagus and heart.

Peristernal chrondritis or perichondritis, conditions referred to as "Tietze's syndrome", pertain to the finding of a tender, nonsuppurative swelling at the xiphisternal, costochondral, sternoclavicular, or manubriosternal junctions.

Tietze's syndrome manifests most often as pain, with symptoms reminiscent of cardiac, pulmonary, abdominal, or other serious diseases.[9] The confusing presentation likely arises due to somatovisceral reflexes involving nerves that supply the body wall, local organs, and possibly the nervi vasorum of the internal thoracic arteries. At CV 16, the internal thoracic arteries course close to the xiphisternal joint (see Figure 13-39) where they are about to enter the posterior, or dorsal, layer of the rectus sheath. Nerves supplying the joint as well as the vessels may become compressed when the stomach fills with food and fluids; the problem will worsen in obese individuals. Tietze's syndrome may also be confused with ruptured peptic ulcer, duodenal ulcer, pancreatitis, epigastric hernia, and hiatal hernia.

The stomach lies close to CV 16, as seen in Figure 13-39. A full

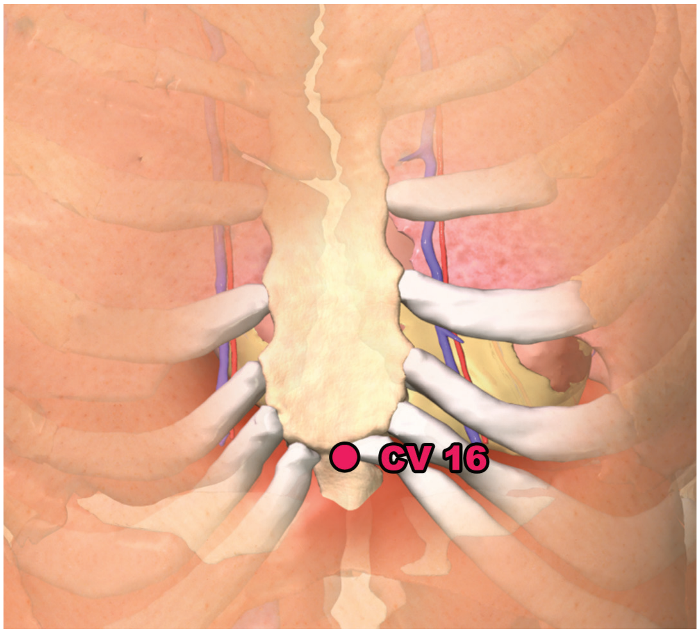

Figure 13-38A. CV 16, as the "Central Courtyard" or "Central Palace", hovers near the heart, the sovereign organ, or emperor in Chinese medicine. Indeed, the heart appears in this image through a window in the chest. Note the relationship of the muscular thoracic diaphragm to the xiphoid process in this image. The vena cava is revealed here as a reminder of the connection between the CV channel, this singular vessel, and its tributaries.

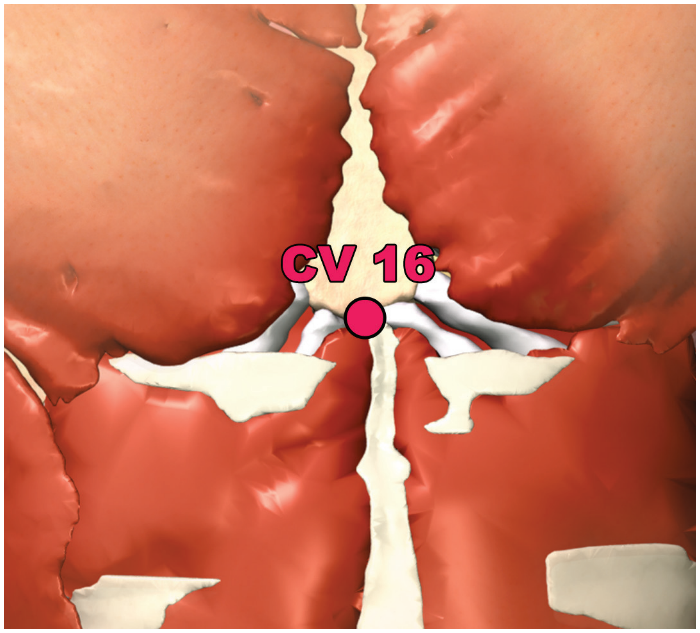

Figure 13-38B. CV 16 marks the site of muscular attachment involving the rectus abdominis, pictured here, and the diaphragm, seen in Figure 13-38A. No wonder the xiphisternal junction can develop pain and inflammation (i.e., costochondritis).

stomach and obese belly increase the likelihood of xiphisternal costochondritis due to heightened intra-abdominal pressure. Nearly half of patients experience increased pain after a meal. Most report that digital pressure on the xiphisternal junction reproduces the symptoms.

Diagnosis is based on finding tenderness to palpation at CV 16; palpation of the xiphisternal junction should take place in any patients complaining of pain in the thorax, shoulders, or cranial abdomen. Remember, however, that both a somatic and visceral problem could co-occur. If local nerve block or acupuncture alleviates the pain, this suggests that xiphisternal somatic dysfunction caused the problem, although re-evaluation should be planned.

Nerves

- **5th and 6th intercostal nerves:** Supply the skin.

Clinical Relevance: Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) may produce chronic pain syndromes such as postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[10] The latter arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves that meet along the CV channel. The neuromas typically appear on the left intercostal spaces and arise where sternal wires or needles were inserted at the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

A wide array of somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27 as well as the sternum itself, from CV 16 to CV 21. These problems include costochondritis, physical trauma, upper thoracic somatic dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Mechanisms involve somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve "unhappiness" as well as upper thoracic spinal cord changes resulting from nociceptive afferent bombardment originating in dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

- **Internal thoracic artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicles and 1st costal cartilages. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[11]
- **Internal thoracic vein:** The internal thoracic veins develop as venae comitantes of the internal thoracic arteries; they are frequently paired either unilaterally or bilaterally. The internal thoracic veins may form a single or double arch at CV 16 and connect deep to the xiphoid process.[12] The anterior intercostal veins serve as tributaries of the internal thoracic veins.

Clinical Relevance: Microvascular transfers involving the internal thoracic vessels offer rich opportunities for tissue transfer, but require consideration of the unique anatomy of each patient in order to avoid serious complications. Should such difficulties occur, acupuncture and laser therapy may aid in the recovery of circulation to the site, as appropriate.

The internal thoracic vessels (formerly known as the internal mammary vessels) connect to the superior epigastric vessels. View them in cross section at CV 16 in Figure 13-39. At each intercostal space, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[13]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Thoracic issues of chest pain or fullness, rib pain, anxiety:** CV 16, CV 17, CV 14, PC 5, PC 2, BL 15, BL 16, local points, KI 27, KI 10, KI 3, BL 60.
- **Abdominal problems such as gastroesophageal reflux disease (GERD):** CV 16, CV 14, CV 12, CV 22, PC 6, ST 36, LR 3.
- **Hiccoughs (Hiccups):** Acupressure at CV 16.
- **Emotional stress and apprehension:** Acupressure at CV 16 to aid in releasing the diaphragm and relieving precordial tension.
- **Esophageal tension or a foreign body (e.g., a "stuck" potato chip):** CV 16, CV 17, tender points along the sternum, CV 21.

Figure 13-39. The Central Courtyard, CV 16, indicates the juncture of two different bodily worlds: the thorax and abdomen. The thoracic diaphragm separates them, as shown by this cross section, enveloping the trunk from xiphoid to vertebra. Note the numerous internal thoracic vessels on either side of the midline surrounding the xiphoid. The vessels connect from rectus sheath to parasternal groove.

Evidence-Based Applications

- Acupuncture-like stimulation of the truncal region in the vicinity of CV 16 activated lower thoracic spinal nerves, leading to reflex regulation of **gastric motility** via the gastric sympathetic nerves in a spinal segmental fashion.[1]
- Acupuncture applied to CV 17 reduced the heart rate and increased the power of the high-frequency component of **heart rate variability** (an indicator of cardiac vagal activity), whereas acupuncture at CV 16 did not.[14]

CV 17

Shan Zhong "Chest Center"

On the ventral midline, level with the 4th intercostal space. Approximately between the nipples in males.

Caution: Do not needle deeply; should the patient have one at CV 17, a patent sternal foramen might allow needle passage through the sternum and into the heart, risking cardiac tamponade or other potentially fatal injury.[1]

Bones

- **Body of sternum:** Younger individuals have four sternebrae in place of a consolidated sternum. These sternebrae articulate with each other via sternal synchondroses, or primary cartilaginous joints. The sternebral joints usually fuse, starting at the caudal portion, between the time of puberty and the mid-twenties. Ridges along the sternum designate lines of fusion, or synostoses.

Clinical Relevance: Sternal foramina sometimes remain patent. This can make deep needling over sternal foramina life-threatening if a wayward needle enters the heart. Sternal foramina exist in 4% of females and 10% of males.[2] Standard chest radiographs may not indicate which foramina remain open.

Nerves

- **Fourth intercostal nerve:** Supplies the skin.

Clinical Relevance: Like other CV points, CV 17 confers its benefits through somatic afferent stimulation of bilateral intercostal nerves. These ventral rami supply strips of muscle and skin around the trunk. Somatic afferent stimulation at CV points interact with interneurons in the gray matter of the spinal cord, affecting organs innervated by the same spinal cord segments.

Chinese medicine associates CV 17 with the pericardium as its Front Mu point. While the pericardium does lie close to CV 17 as shown in Figures 13-40 and 13-41, the cardiac plexus, not the pericardium, is what produces the physiologic changes traditionally attributed to the pericardium. The cardiac plexus houses both sympathetic and vagal nerve branches; it resides in the epicardium, a thin layer of mesothelium formed by the visceral layer of the serous pericardium.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) may produce chronic pain syndromes such as postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[7] The latter arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves that meet along the CV channel. The neuromas typically appear on the left intercostal spaces and arise where sternal wires or needles were inserted at the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

Both somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27 as well as the sternum itself, from CV 16 to CV 21. These problems include costochondritis, physical trauma, upper thoracic somatic dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Mechanisms involve somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve irritation as well as upper thoracic spinal cord "wind-up" secondary to nociceptive afferent bombardment by nerves ferrying neural traffic from dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

- **Internal thoracic artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[8]
- **Internal thoracic vein:** The internal thoracic veins develop as venae comitantes of the internal thoracic arteries; they are frequently paired either unilaterally or bilaterally. The internal thoracic veins may form a single or double arch at CV 16 and

Figure 13-41. This cross-section at CV 17, "Chest Center", contains organs from the thorax as well as the abdomen. Most importantly, this image reveals the connection between CV 17 and the pericardium, i.e., the structure associated with this Front Mu point.

connect deep to the xiphoid process.[9] The anterior intercostal veins serve as tributaries of the internal thoracic veins.

Clinical Relevance: Microvascular transfers involving the internal thoracic vessels offer rich opportunities for tissue transfer, but require consideration of the unique anatomy of each patient in order to avoid serious complications. Should such difficulties occur, acupuncture and laser therapy may aid in the recovery of circulation to the site, as appropriate.

The internal thoracic vessels (formerly known as the internal mammary vessels) connect to the superior epigastric vessels. At each intercostal space, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[10]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Anxiety, stress, tension:** CV 17, HT 7, LR 3, GV 20, Yintang (GV 24.5).
- Cardiopulmonary or thoracic problems; e.g., dyspnea, hiccough, chest pain, palpitations, cough, asthma, bronchitis, pleuritis, intercostal neuralgia: CV 17, local points that are tender to palpation on chest wall, CV 15, CV 22, KI 21, LU 7, ST 36,
- Lactation insufficiency, mastitis: CV 17, SI 1, SI 11, ST 18.
- Nausea, vomiting: CV 17, PC 6, ST 36.
- Esophageal tension or a foreign body (e.g., a "stuck" potato chip): CV 16, CV 17, tender points along the sternum, CV 21.

Evidence-Based Applications

- Acupuncture at CV 6, CV 12, CV 17, ST 36, and SP 10 conferred protective effects on cognitive impairments caused by multi-infarction dementia in rats, suggesting it may benefit patients with **vascular dementia.**[3]
- Acupuncture at LI 4, ST 36, PC 6, LR 3, CV 12, CV 17, and CV 22 successfully treated **sleep-related laryngospasm** with gastroesophageal reflux, refractory to current medical treatment; results were maintained at a 1-year follow-up assessment, and no evidence of reflux was detected upon repeated upper gastrointestinal study.[4]
- In rats, acupuncture at CV 17, LU 1, ST 36, SP 6, GV 14, and BL 13 effectively reduced the sizes of experimentally induced **immune-mediated pulmonary inflammatory lesions.**[5]
- Following **acute myocardial infarction,** patients receiving acupuncture at CV 14, CV 17, ST 36, PC 6, and SP 6 demonstrated the following changes: reduced blood viscosity and myocardial oxygen consumption, improved microcirculation and left ventricular function, improved collateral circulation, and reduced the area of infarction.[6]
- Acupuncture at CV 17, PC 6, HT 7, GV 20, and Yintang (GV 24.5) reduced **anxiety** in women receiving *in vitro* fertilization.[11]
- Acupuncture applied to CV 17 **reduced the heart rate** and

increased the power of the high-frequency component of heart rate variability (an indicator of cardiac vagal activity), whereas acupuncture at CV 16 did not.[12]

CV 18

Yu Tang “Jade Hall”

On the ventral midline at the level of the 3rd intercostal space. To locate the 3rd intercostal space, first find the sternomanubrial junction, also called the “Angle of Louis”. This identifies the level of the 2nd rib. Count down two intercostal spaces to reach the 3rd intercostal location CV 18 resides on the midline.

Caution: Do not needle deeply; should the patient have a patent sternal foramen, the needle may pass through the sternum and into the heart, risking cardiac tamponade or other injury.[1] Review the relationship of CV 18 to the heart in Figure 13-43.

Bones

- **Body of sternum:** Younger individuals have four sternebrae in place of a consolidated sternum. These sternebrae articulate with each other via sternal synchondroses, or primary cartilaginous joints. The sternebral joints usually fuse, starting at the caudal portion, between the time of puberty and the mid-twenties. However, they may remain open lifelong. Ridges along the sternum designate lines of fusion, or synostoses.

Clinical Relevance: Sternal foramina sometimes remain patent. In such individuals, deep needling can cause serious injury if a wayward needle enters the heart.

Sternal foramina exist in 4% of females and 10% of males.[2] Standard chest radiographs may not indicate which foramina continue to exist.

In that the sternum structurally supports the stability of the thoracic spine in flexion-extension, side-bending, and axial rotation, fracture of the bone significantly reduces thoracic integrity and stabilization.[3]

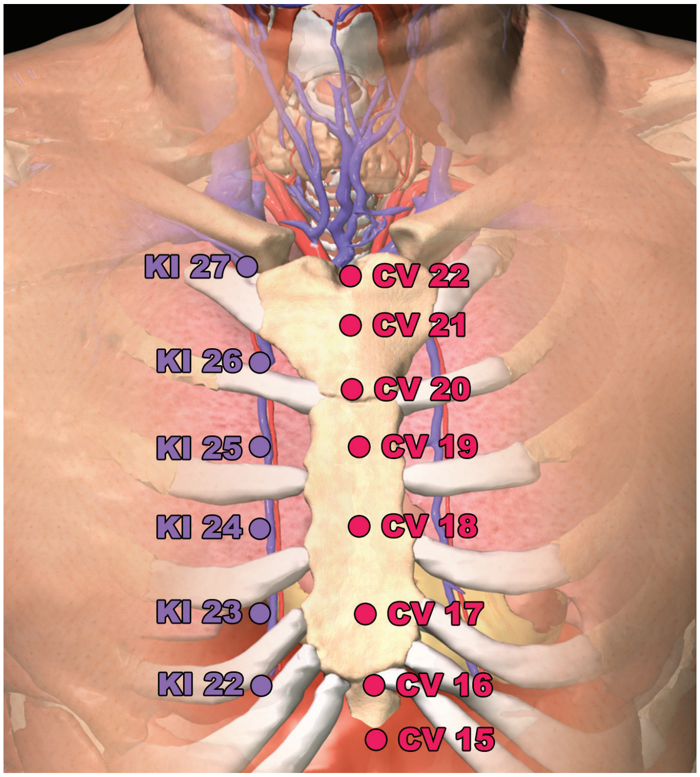

Figure 13-42. Applications for CV 18 pertain to mainly local pain, anxiety, and esophageal motility disorders. Acupressure works well at sternal CV points; patients can perform self-treatment readily and regularly.

Nerves

- **3rd intercostal nerve:** Supplies the skin.

Clinical Relevance: Like other CV points, CV 18 confers its benefits through somatic afferent stimulation of bilateral intercostal nerves. These ventral rami supply strips of muscle and skin around the trunk. Somatic afferent stimulation at CV points interact with interneurons in the gray matter of the spinal cord, affecting organs innervated by the same spinal cord segments.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) may produce chronic pain syndromes such as postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[4] The latter arises from two potential pathologies: trigger points along the parasternal “corridor” (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves that meet along the CV channel. The neuromas typically appear on the left intercostal spaces and arise where sternal wires or needles were inserted at the intercostal spaces. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

Both somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal “corridor” demarcated by the KI channel from KI 22 to KI 27 as well as the sternum itself, from CV 16 to CV 21. These problems include costochondritis, physical trauma, upper thoracic somatic dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Mechanisms involve somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve irritation as well as upper thoracic spinal cord “wind-up” secondary to nociceptive afferent bombardment by nerves ferrying neural traffic from dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

- **Internal thoracic artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax posterior to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in an inferior direction posterior to the superior six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the

epigastric arteries and then on to the limbs.[5]

- **Internal thoracic vein:** The internal thoracic veins develop as venae comitantes of the internal thoracic arteries; they are frequently paired either unilaterally or bilaterally. The internal thoracic veins may form a single or double arch at CV 16 and connect deep to the xiphoid process.[6] The anterior intercostal veins serve as tributaries of the internal thoracic veins.

Clinical Relevance: Microvascular transfers involving the internal thoracic vessels offer rich opportunities for tissue transfer, but require consideration of the unique anatomy of each patient in order to avoid serious complications. Should such difficulties occur, acupuncture and laser therapy may aid in the recovery of circulation to the site, as appropriate.

The internal thoracic vessels (formerly known as the internal mammary vessels) connect to the superior epigastric vessels. At each intercostal space, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[7]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Local pain:** CV 18, KI 27, and regional tender points.
- **Anxiety:** CV 18, HT 7, BL 10, SP 6.
- **Esophageal motility issues:** Acupressure along sternal midline, including CV 18, as well as local points in the epigastrium and CV 22.

CV 19

Zi Gong "Purple Palace"

On the ventral midline, at the level of the 2nd intercostal space, found just caudal to the sternomanubrial junction, or "Angle of Louis", which is a readily palpable landmark. Refer to Figure 13-44 for relative location of the sternomanubrial junction (that finds the 2nd rib) and CV 19 at the adjacent intercostal space.

Caution: Do not needle deeply. Inserting a needle through sternal foramen at CV 19 might enter the heart, as illustrate by Figure 13-45. Fatal injury may ensue.[1]

Bones

- **Body of sternum:** Younger individuals have four sternebrae in place of a consolidated sternum. These sternebrae articulate with each other via sternal synchondroses, or primary cartilaginous joints. The sternebral joints usually fuse, starting at the caudal portion, between the time of puberty and the mid-twenties. However, they may remain open lifelong. Ridges along the sternum designate lines of fusion, or synostoses.

Clinical Relevance: Sternal foramina sometimes stay patent throughout life. In such individuals, deep needling can cause serious injury if a wayward needle enters the heart. Sternal foramina exist in 4% of females and 10% of males.[2] Standard chest radiographs may not indicate which foramina continue to exist.

In that the sternum structurally supports the stability of the thoracic spine in flexion-extension, side-bending, and axial rotation, fracture of the bone significantly reduces thoracic integrity and stabilization.[4] In such instances, acupuncture and related techniques could prove beneficial to address myofascial restriction and neuropathic pain.

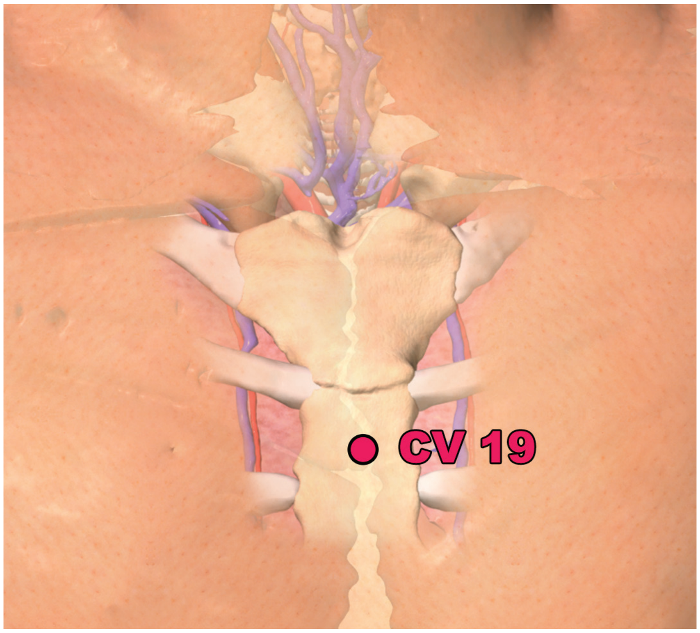

Figure 13-44. CV points located on the sternum have treatment applications for anxiety and apprehension perceived as chest discomfort. Of course, do not assume that chest pain is non-cardiogenic unless ruled out satisfactorily, but acupuncture and related techniques can aid in alleviating the precordial discomfort that noncardiac causes incite. Palpate the entire sternum and precordium for trigger points or tenderness to palpation and select as needed to help dissipate the tension through systemic and segmental neuromodulation.

Nerves

- **2nd intercostal nerve:** Supplies the skin.

Clinical Relevance: Like other CV points, CV 19 confers its benefits through somatic afferent stimulation of bilateral intercostal nerves. These ventral rami supply strips of muscle and skin around the trunk. Somatic afferent stimulation at CV points interact with interneurons in the gray matter of the spinal cord, affecting organs innervated by the same spinal cord segments.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) may produce chronic pain syndromes such as postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[5] The latter arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves that meet along the CV channel. The neuromas typically appear on the left intercostal spaces and arise where sternal wires were inserted. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

Both somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27 as well as the sternum itself, from CV 16 to CV 21. These problems include costochondritis, physical trauma, upper thoracic somatic dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Etiopathogenesis involves somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve irritation as well as upper thoracic spinal cord "wind-up" secondary to nociceptive afferent bombardment by nerves ferrying neural traffic from dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

- **Internal thoracic artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax dorsal to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in a caudal direction dorsal to the cranial six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[6]

Figure 13-45. "Purple Palace", the alternate name for CV 19, describes the blood-filled heart and major vessels that ancient anatomists would have found at this level. Furthermore, in keeping with the astrological allusions once finds in Chinese medicine, a star named "Purple Palace" exists in the "Celestial Emperor" Constellation.

as venae comitantes of the internal thoracic arteries; they are frequently paired either unilaterally or bilaterally. The internal thoracic veins may form a single or double arch at CV 16 and connect deep to the xiphoid process.[7] The anterior intercostal veins serve as tributaries of the internal thoracic veins.

Clinical Relevance: Microvascular transfers involving the internal thoracic vessels offer rich opportunities for tissue transfer, but require consideration of the unique anatomy of each patient in order to avoid serious complications. Should such difficulties occur, acupuncture and laser therapy may aid in the recovery of circulation to the site, as appropriate.

The internal thoracic vessels (formerly known as the internal mammary vessels) connect to the superior epigastric vessels. At each intercostal space, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[8]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Deep substernal pain and occasional soreness over the sternum:** Consider referred pain from the sternalis muscle. Address local trigger points such as KI 25 and KI 26. Add KI 27 and CV 19 if tender to palpation.
- **Pleuritis, cough, tracheitis, dyspnea, bronchitis:** CV 19, CV 17, CV 22, LU 1, LU 2, ST 36.
- **Anxiety:** Palpate for tender locations on the CV line over the sternum, such as CV 19, CV 18, and CV 17. Consider adding HT 7, ST 36, LR 3, and/or GV 20.
- **Dysphagia:** Acupressure at CV 19, CV 17, and CV 22 as needed.
- **Esophageal motility issues:** Acupressure along sternal midline, including CV 19 and 18, as well as local points in the epigastrium and CV 22.

Evidence-Based Applications

- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LR 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[3]

CV 20

Hua Gai "Magnificent Canopy"

"Florid Canopy"

On the ventral midline at the manubriosternal synchondrosis (sternal angle), approximately at the caudal extent of the 1st intercostal space or adjacent to the 2nd rib.

Caution: Do not needle deeply. Should an incomplete synchondrosis exist at CV 20, deep needling may injure contents of the mediastinum.[1] Examine the relationship between CV 20, the vena cava, and the aortic arch in Figure 13-48.

Synchondrosis

- **Sternal angle (Angle of Louis):** The level where the trachea bifurcates into the right and left bronchi. The azygous vein meets the superior vena cava at this level, the aortic arch expresses its convexity and the pulmonary bifurcation usually lands caudal to this level, at T5-6.

Clinical Relevance: The sternal angle most commonly coincides with the T4/5 intervertebral disk space in males and the T4 vertebra in females. However, the potential range of planar coincidence spans from the caudal half of T2 to that of T6.[2] The sternal angle thus serves as a landmark not only for CV 20, but also other structures of anatomic importance.

Nerves

- **1st intercostal nerve:** Supplies the skin.

Clinical Relevance: Like other CV points, CV 20 confers its benefits through somatic afferent stimulation of bilateral intercostal nerves. These ventral rami supply strips of muscle and skin around the trunk. Somatic afferent stimulation at CV points interact with interneurons in the gray matter of the spinal cord, affecting organs innervated by the same spinal cord segments.

Heart surgery (coronary grafting, with or without concurrent aortic valve replacement) may produce chronic pain syndromes such as postcardiotomy syndrome, brachial plexopathy, and post-sternotomy neuralgia.[3] The latter arises from two potential pathologies: trigger points along the parasternal "corridor" (the last segment of the KI channel) and/or scar-entrapped neuromas of the ventral rami of the first 4-6 intercostal nerves that meet along the CV channel. The neuromas typically appear on the left intercostal spaces and arise where sternal wires were inserted. Tension on the wires may incite a strong wound healing reaction, more commonly on the left because, perhaps, surgeons tie the wires on the left. While the painful areas do appear to respond to local anesthetic or neurolytic injection, treatment with acupuncture and related techniques such as laser therapy would be worthwhile to try before a more invasive mode of therapy.

Both somatic and visceral sources of dysfunction can cause tenderness to palpation along the parasternal "corridor" demarcated by the KI channel from KI 22 to KI 27 as well as the sternum itself, from CV 16 to CV 21. These problems include costochondritis, physical trauma, upper thoracic somatic dysfunction, cardiac or pulmonary conditions (e.g., angina, myocardial ischemia, bronchial disorders), digestive problems (e.g., gastroesophageal reflux disorder, acid reflux, dyspepsia, hiatal hernia), and emotional upset (panic attack, stress, loss). Etiopathogenesis involves somato-somatic and viscerosomatic reflexes as well as irritation of the intercostal nerves themselves. Neuromodulation addresses peripheral nerve irritation as well as upper thoracic spinal cord "wind-up" secondary to nociceptive

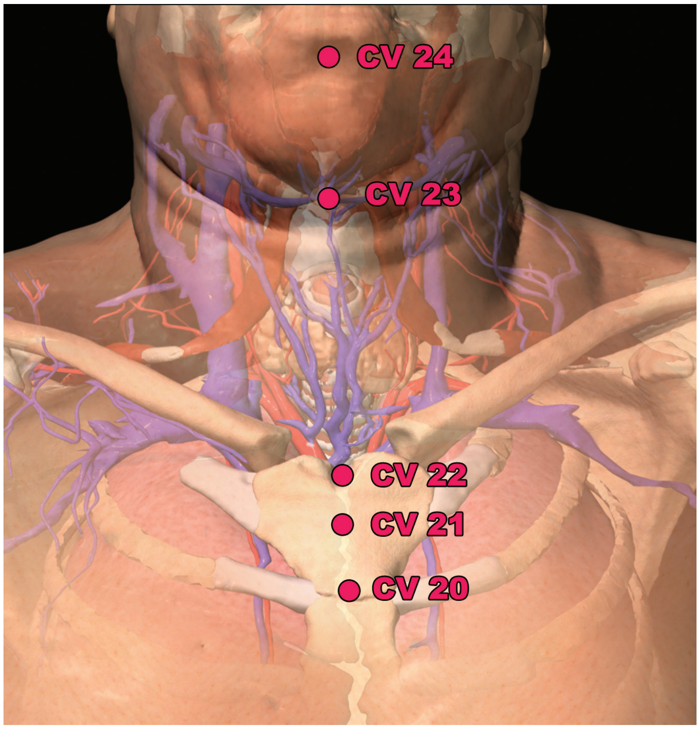

Figure 13-46. CV 20 sits at the sternal angle, as shown in this image. "Florid Canopy" may refer to the canopy of vessels draped over the neck and shoulders.

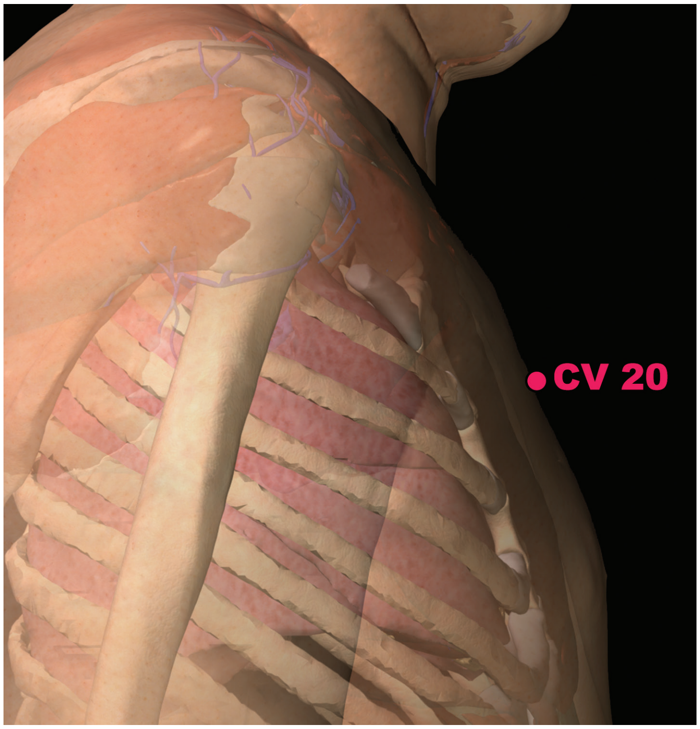

Figure 13-47. The "Magnificent Canopy" associated with CV 20 may describe the way the lungs drape over the heart as a canopy, similar to the umbrella that shaded the emperor's wagon when he toured the countryside.

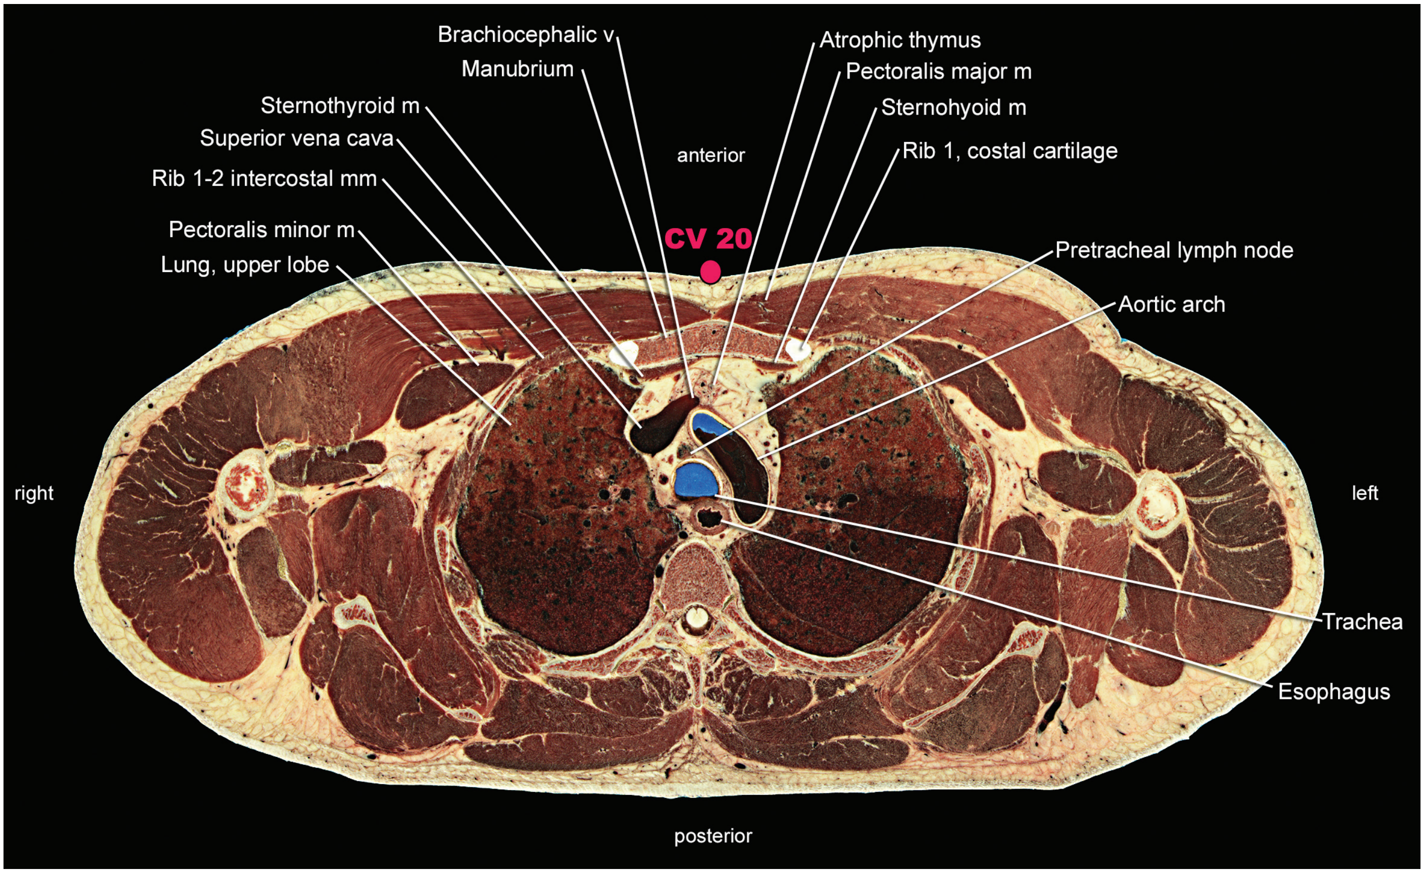

Figure 13-48. CV 20 exists on the same horizontal plane as structures associated with its clinical indications. These include the lungs (lower respiratory problems), trachea (cough, tracheal irritation), and chest wall pain (pectoralis major muscle).

afferent bombardment by nerves ferrying neural traffic from dysfunctional organs, muscles, tendons, or nearby tissues.

Vessels

- **Internal thoracic artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax dorsal to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in a caudal direction dorsal to the cranial six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[4]
- **Internal thoracic vein:** The internal thoracic veins develop as venae comitantes of the internal thoracic arteries; they are frequently paired either unilaterally or bilaterally. The internal thoracic veins may form a single or double arch at CV 16 and connect deep to the xiphoid process.[5] The anterior intercostal veins serve as tributaries of the internal thoracic veins.

Clinical Relevance: Microvascular transfers involving the internal thoracic vessels offer rich opportunities for tissue transfer, but require consideration of the unique anatomy of each patient in order to avoid serious complications. Should such difficulties occur, acupuncture and laser therapy may aid in the recovery of circulation to the site, as appropriate.

The internal thoracic vessels (formerly known as the internal mammary vessels) connect to the superior epigastric vessels. At each intercostal space, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[6]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Deep substernal pain and occasional soreness over the**

sternum: Rule out cardiac origin. Consider referred pain from the sternalis muscle. Address local trigger points such as KI 25 and KI 26. Add KI 27 and CV 20 if tender to palpation.

- **Pleuritis, cough, tracheitis, dyspnea, bronchitis:** CV 20, CV 22, CV 17, LU 1, LU 2, ST 36. Consider acupressure at CV points.
- **Dysphagia:** Acupressure at CV 20, CV 17, and CV 22 as needed.
- **Esophageal motility issues:** Acupressure along sternal midline, at points that ease the disorder from CV 20 to CV 21.
- **Anxiety:** Palpate for tender locations on the CV line over the sternum, such as CV 20, CV 18, and CV 17. Consider adding HT 7, ST 36, LR 3, and/or GV 20.

CV 21

Xuan Ji "Jade Pivot"

On the ventral midline, in the center of the manubrium, approximately midway between CV 20 and CV 22.

Bones

- **Manubrium:** A triangular bone that is the thickest and widest part of the sternum (like the handle of the sword, with the sternal body as the blade). Evaluation of the morphogenesis of the human manubrium reveals that the bone develops in a complex manner as an intersection between derivatives of the neural crest, the lateral plate, and elements of the related somite.[2]

Clinical Relevance: While trigger point injections are usually considered safe, serious complications can happen. These include epidural abscess, necrotizing fasciitis, gas gangrene, and osteomyelitis.[3] Trigger point injections in the vicinity of KI 27 for conditions such as dystonia risk causing pneumothorax and retrosternal abscess.[4] Based on the image in Figure 13-50, one can see that the manubrium creates a barrier that prohibits a needle at CV 21 from entering the mediastinum unless a congenital or acquired defect disrupts the integrity of the manubrium.

Nerves

- **Medial supraclavicular nerves (C3, C4):** Supplies the skin of the neck. The supraclavicular nerve is purely sensory and arises as one of the four branches of the superficial cervical plexus. The medial branches courses along the dorsal border clavicular head of the sternomastoid muscle; it then pierces the platysma and supplies sensation to the sternal notch at CV 22. Anatomic variants of the supraclavicular nerve are not uncommon because of the complexity of its morphogenesis.

Clinical Relevance: Supraclavicular nerve entrapment syndrome can cause shoulder pain in the anterior shoulder; it often arises as a consequence of anatomic variants such as osseous anomalies, fibrous bands, and muscle or tendon pressure.[5]

Supraclavicular nerve entrapment can follow clavicular fracture; portions of the nerve may become entrapped within the fracture callus.[6] Occasionally, painful neuromas develop. Treatment of neuropathic supraclavicular nerves with acupuncture and related techniques would likely involve ST 12 and ST 13 along with ST 11, KI 27, and CV 21.

Vessels

- **Internal thoracic artery:** The internal thoracic arteries arise from the subclavian arteries and descend into the thorax dorsal to the clavicle and 1st costal cartilage. The internal thoracic arteries run slightly lateral to the sternum on the internal surface of the thoracic cavity. The internal thoracic arteries continue in a caudal direction dorsal to the cranial six costal cartilages and their respective internal intercostal muscles. At the level of the 6th intercostal space, the internal thoracic arteries divide into the superior epigastric and musculophrenic arteries. The internal thoracic artery provides a collateral arterial pathway to the pelvic limbs in the event of vaso-occlusive disease. When both common iliac arteries obstruct, the internal thoracic arteries transmit blood to the epigastric arteries and then on to the limbs.[7]
- **Internal thoracic vein:** The internal thoracic veins develop as venae comitantes of the internal thoracic arteries; they are frequently paired either unilaterally or bilaterally. The internal thoracic veins may form a single or double arch at CV 16 and

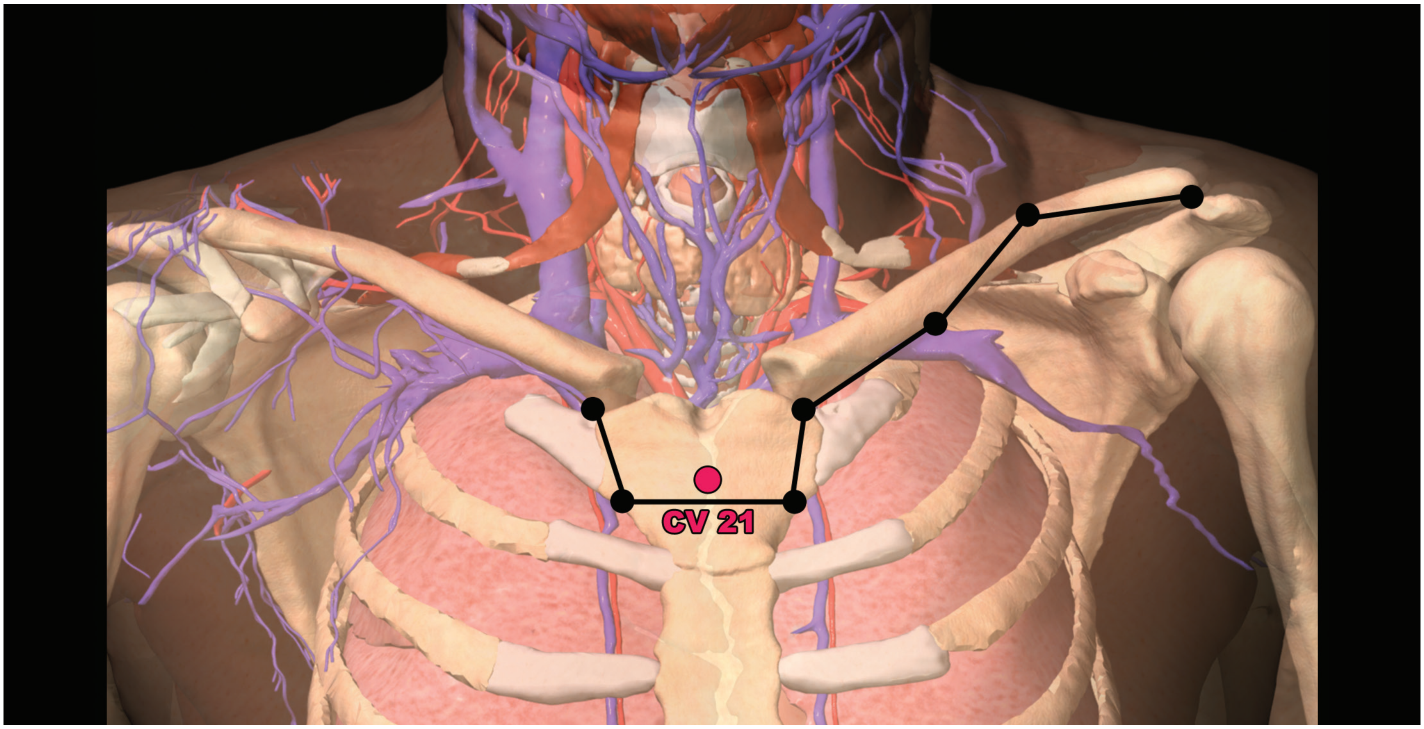

Figure 13-49. Like CV 19 (Purple Palace) and CV 20 (Florid Canopy), the Chinese name for CV 21 (Xuan Ji) carries astrological connotations. Stars the Chinese called Xuan and Ji occupy the second and third stars (i.e., the bottom) in the bowl of the Big Dipper constellation. In addition, the term "Jade Pivot" or "Jade Swivel" speaks of the way in which the neck rotates atop the thorax.

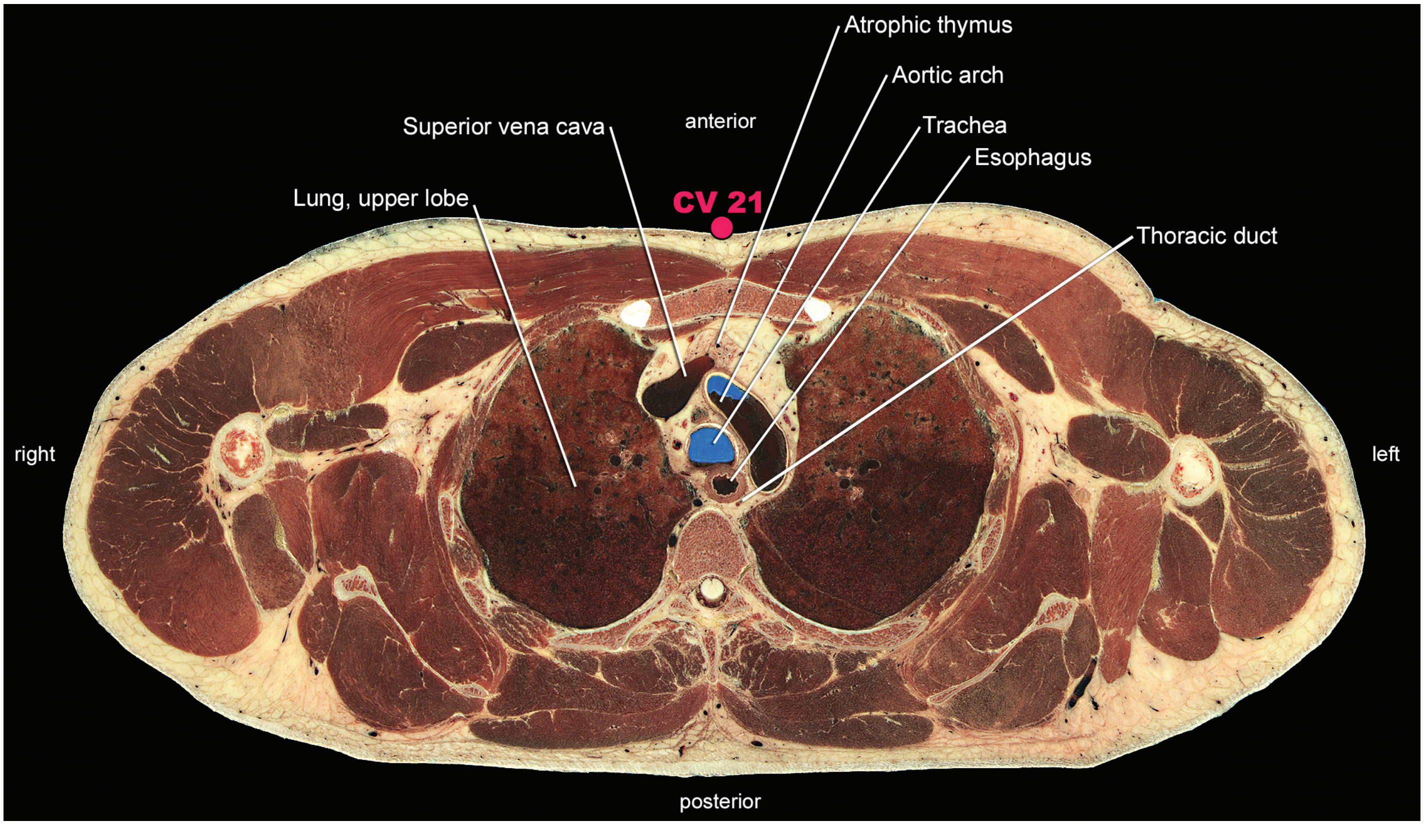

Figure 13-50. The effects of treating CV 21 with acupuncture and related techniques on the thymus, trachea, esophagus, thoracic duct, and major vessels may result from spinal segmental; i.e., somatovisceral, reflexes and/or relaxation of the cranial thorax following release of tension in the manubrial and mediastinal fascia.

connect deep to the xiphoid process.[8] The anterior intercostal veins serve as tributaries of the internal thoracic veins.

Clinical Relevance: Microvascular transfers involving the internal thoracic vessels offer rich opportunities for tissue transfer, but require consideration of the unique anatomy of each patient in order to avoid serious complications. Should such difficulties occur, acupuncture and laser therapy may aid in the recovery of circulation to the site, as appropriate.

The internal thoracic vessels (formerly known as the internal mammary vessels) connect to the superior epigastric vessels. At each intercostal space, the internal thoracic vessels connect to the intercostal arteries and veins. In addition, perforating branches extend mediad to the sternum (CV line). By dint of their connection with the epigastric channels, the internal thoracic vessels provide collateral flow in the event of aorto-iliac obstruction or ligation.[9]

Patients requiring coronary artery bypass graft (CABG) could also have common iliac artery occlusion. That is, many are at high risk of associated atherosclerotic arterial disease affecting peripheral vessels. Thus, these patients are at risk of developing severe ischemia of the pelvic limb if the surgeon selects the internal thoracic artery as a replacement vessel. Thus, preoperative assessment should be performed prior to CABG to evaluate whether the internal thoracic artery has already been recruited to participate in the internal thoracic artery – inferior epigastric artery collateral supply. Interrupting this collateral pathway threatens the limb, especially in conjunction with hemodynamic compromise such as insufficient perfusion during bypass and low cardiac output after surgery.

Indications and Potential Point Combinations

- **Deep substernal pain and occasional soreness over the sternum; rule out cardiac origin:** Consider referred pain from the sternalis muscle. Address local trigger points such as KI 25 and KI 26. Add KI 27 and CV 21 if tender to palpation.
- **Pleuritis, cough, tracheitis, dyspnea, bronchitis:** CV 21, CV 17, CV 22, LU 1, LU 2, ST 36. Consider acupressure at CV points.
- **Dysphagia:** Acupressure at CV 21, CV 17, and CV 22 as needed.
- **Gastroesophageal reflux disease (GERD), esophageal motility disorders:** CV 21, CV 22, CV 14, CV 12, ST 36, LR 3.
- **Esophageal motility issues:** Acupressure along sternal midline, at points that ease the disorder from CV 20 to CV 21.
- **Tonsillitis, pharyngitis:** CV 20, ST 9, ST 10, LI 4, LI 11, LU 7. Acupressure at CV 21 and CV 22.

Anxiety before public speaking or an interview: Palpate for tender locations on the CV line over the sternum, such as CV 21, CV 20, CV 18, and CV 17. If performing acupressure on oneself, realize that treatment of these sites just before the speaking engagement may reveal erythema to the audience or interviewer. As such, one may reserve this form of self-relaxation for times when wearing apparel that will cover the treatment zone.

Evidence-Based Applications

- LI 4, CV 21, and CV 22 improved **cancer-related breathlessness.**[1]

CV 22

Tian Tu

“Celestial Chimney”

On the ventral midline, just cranial to the jugular (suprasternal) notch.

HIGH RISK POINT!

Potential complications: Tracheal or aortic arch puncture, pneumothorax, bleeding from jugular venous arch puncture with deep needing. Review the local anatomy in Figure 13-52.

Avoid local needling in cases of thyroid cancer.

Viscera

- **Trachea:** A fibrocartilaginous tube supported by cartilaginous, incomplete tracheal rings. The brachiocephalic trunk resides on the right side of the trachea.

Clinical Relevance: The urge to cough stems from tracheal, laryngeal, or bronchial stimulation of mechanoreceptors attached to A-delta fibers or or chemoreceptor activation connected to C fibers.[3] Afferent vagal pathways create the urge to cough as reflexes occur in the Botzinger ventral respiratory locus of the brainstem. Efferent motor nerves cause contractions in the glottis, thoracic diaphragm, and abdominal muscles. A cough results. Sensitization of the afferent vagal nerve endings within the trachea accentuates the urge to cough. Acupuncture and related techniques applied to CV 22 and other relevant points may dampen the irritability of the cough reflex.

Glands

- **Thymus gland:** In the superior mediastinum, in the space between the trachea and manubrium. Following puberty, the gland involutes and fat replaces much of the glandular tissue. While remnants of the atrophic thymus remain in the cross section at this level (see Figure 13-52), it shows more clearly in Figure 13-50. In 20% to 25% of humans, islands of thymic tissue occur in the tympanic cavity, neck, mediastinum, or lung. These “extra-thymic” loci relate to its development and origin in the endoderm of the third and possibly 4th branchial pouches early in gestation.[4]

Clinical Relevance: Although no evidence indicates that acupuncture or related techniques impact thymic function, local and somatovisceral reflexes engendered by somatic afferent stimulation at CV 22 may influence nerve signals and circulation to and from the thymus.

Nerves

- **Vagus nerve (CN X):** A branch of the vagus nerve innervates the thymus gland. The vagus nerve exits from the jugular foramen, passes between the internal jugular vein (IJV) and the common carotid artery inside the carotid sheath. The right vagus nerve passes anterior to the subclavian artery and posterior to the brachiocephalic vein and sternoclavicular joint, on its way to the thorax. The left vagus nerve passes between the left common carotid artery and left subclavian artery, entering the thorax posterior to the sternoclavicular joint. The right and left recurrent laryngeal nerves branch from the vagus in the inferior part of the neck. Some cardiac branches also arise in the neck.
- **Sympathetic fibers:** Sympathetic fibers innervate the thymus gland. Sympathetic trunks derive presynaptic fibers from the superior thoracic spinal nerves. Branches destined to cervical viscera and the head course with the arteries, particularly the vertebral and carotid arteries.
- **Phrenic nerve (C3, C4, C5):** Provides sensation to the thymus gland capsule. The phrenic nerve contains sensory, motor, and sympathetic fibers. It provides the only motor input to the diaphragm and carries sensory fibers from the central part of the diaphragm. The phrenic nerve also supplies the pericardium and mediastinal pleura.
- **Medial supraclavicular nerves (C3, C4):** The supraclavicular nerves send branches to the neck to supply the skin. The medial branches course along the dorsal border clavicular head of the sternocleidomastoid muscle; they then pierce the platysma and supply sensation to the sternal notch at CV 22. Anatomic variants of the supraclavicular nerve are not uncommon because of the complexity of its morphogenesis.

Clinical Relevance: Several nerves contribute branches to the thymus. These include the descending vagus, phrenic, hypoglossal, and sometimes the recurrent laryngeal.[5] Whether acupuncture-based neuromodulation of these nerves could affect thymic function is unknown at this time.

Vessels

- **Anterior intercostal arteries:** Supply the thymus gland.
- **Anterior mediastinal branches of the internal thoracic arteries:** Supply the thymus gland.
- **Jugular venous arch:** The right and left anterior jugular veins may unite in the suprasternal space, superior to the manubrium, to form the jugular venous arch.
- **Thyroid ima artery:** In some cases, the brachiocephalic trunk gives off a small, unpaired thyroid ima artery, otherwise known as the lowest thyroid artery. The thyroid ima artery ascends anterior to the trachea, supplying the trachea along its course

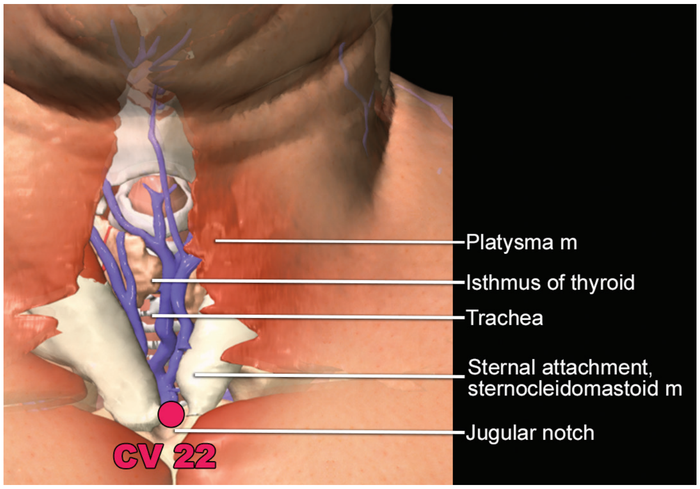

Figure 13-51. The term “Celestial Chimney” for CV 22 describes the proximity of the trachea to the point, as shown here.

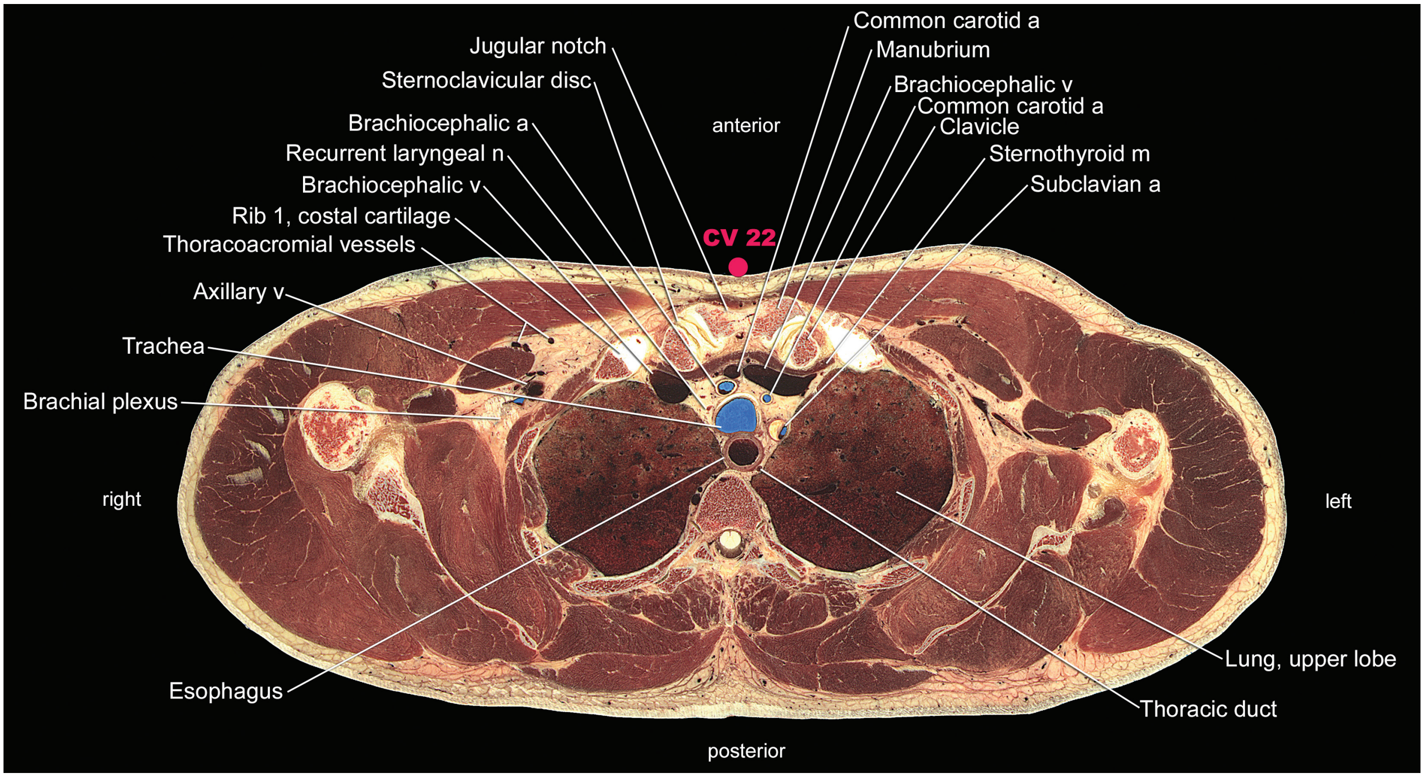

Figure 13-52. This image portrays the proximity of major vessels to CV 22, thereby depicting the dangers of deep needling at this point.

with branches. Variations in ventral cervical vascular anatomy can link the thyroid ima artery to arterial supply for the thymus.[6]

- **Anterior jugular vein:** Begins near the hyoid bone as several superficial veins from the submaxillary region converge. The anterior jugular vein descends between the midline and the ventral border of the sternocleidomastoid muscle. The anterior jugular vein dives deep to the sternal attachment of the sternocleidomastoid muscle and empties into either the external jugular or the subclavian vein. At CV 22, cranial to the manubrium, the right and left anterior jugular veins anastomose by means of a transverse trunk called the venous jugular arch. This venous communication pathway also receives tributaries from the inferior thyroid veins. Each of the inferior thyroid veins communicates with the internal jugular. As such, CV 22 represents a site of venous blood interchange between right and left sides as well as the internal and external jugular venous pathways.
- **Inferior thyroid vein(s):** Drain(s) the inferior poles of the thyroid. As many as four inferior thyroid veins arise from the venous plexus of the thyroid and communicate with the superior and middle thyroid veins. The superior and middle thyroid veins drain into the internal jugular while they inferior thyroid drains into the brachiocephalic vein.
- **Veins of the thymus gland:** Drain into the left brachiocephalic vein, the internal thoracic vein, and the inferior thyroid veins. The venous drainage of the thymus gland does not parallel its arterial supply. Whereas the thymus derives its blood from all local arteries, its three principle sources include the inferior thyroid arteries, the middle thyroid arteries, and the internal thoracic arteries. Venous drainage, on the other hand, empties into the inferior thyroid vein, the superior cava, or the thyroid ima vein.

Clinical Relevance: Thyroid artery variations affect the distribution of autonomic nerve supply by means of nervi vasorum.[7] Damage or surgical removal of an artery may alter the circulation and ability to modulate blood flow due to absence of fibers from the cervical sympathetic chain and its nerves to the thyroid. Neuromodulation with acupuncture and related techniques may aid in supporting recovery of these nerves and restoration of a more healthful level of blood flow.

Levels of thyroglobulin, a product of the thyroid gland, in the inferior-superior thyroid veins measure higher than do those from the antecubital vein.[8] Patients with differentiated thyroid carcinoma that persists or recurs may exhibit a higher ratio of thyroglobulin levels in the internal jugular compared to the antecubital vein.[9] Venous sampling of proteins or peptides secreted by endocrine tumors such as those affecting the thyroid gland can aid in localizing tumors when conventional imaging studies fail to do so. The finding that substances secreted from the thyroid exhibit a higher concentration in local veins than distal ones suggests that acupuncture and related techniques applied to CV 22 may improve distribution of glandular secretions to the systemic circulation.

Indications and Potential Point Combinations

- **Tongue, thyroid, and throat problems:** CV 22, CV 23, ST 9; consider SI 17, LI 4, GV 14, and GV 20.
- **Thoracic problems: cough, asthma, chest congestion, laryngitis, tonsillitis, tracheitis, emphysema, pharyngitis, hiccoughs:** CV 22, LU 5, BL 12, BL 23, LI 4.
- **Vomiting, nausea, dyspepsia:** CV 22, CV 12, PC 6, ST 36, BL 21.

Evidence-Based Applications

- LI 4, CV 21, and CV 22 improved **cancer-related breathlessness.**[1]
- Acupuncture at LI 4, ST 36, PC 6, LR 3, CV 12, CV 17, and CV 22 successfully **treated sleep-related laryngospasm with gastroesophageal reflux,** refractory to current medical treatment; results were maintained at a 1-year follow-up assessment, and no evidence of reflux was detected upon repeated upper gastrointestinal study.[2]

CV 23

Lian Quan "Corner Spring" "Ridge Spring" "Pure Spring"

On the ventral midline at the throat, in a depression immediately cranial to the hyoid bone. Locate by gently running a finger under the chin and toward the throat until it enters a deep hollow in ventral to the hyoid bone.

Caution: Do not needle into a swelling on the floor of the mouth, as it could represent a ranula (i.e., collection of extravasated mucus), a mucus retention cyst from a salivary gland, or a thyroglossal duct cyst, branchial cleft cyst, cystic hygroma, thyroid disease, intramuscular hemangioma, or submandibular sialadenitis.[3]

Muscles

- **Platysma muscle:** The platysma muscle arises in the fascia covering the deltoid and pectoralis major muscles. These fibers sweep over the clavicle to insert on the inferior border of the mandible. Cutaneous nerves pierce the platysma muscle. Conveys expressions of tension, stress, or grimace.
- **Mylohyoid muscle:** Originates on the mylohyoid line of the mandible and inserts onto the hyoid bone. Elevates the hyoid bone and provides a stable but mobile floor to the mouth and muscular sling which lies inferior to the tongue. Raises the tongue during speaking and swallowing. The middle and anterior fibers of the mylohyoid insert onto the median fibrous raphe that extends from the symphysis menti to the hyoid bone (see Figure 13-54).
- **Geniohyoid muscles:** These muscles are superior to the mylohyoid muscles; in this location they reinforce and shorten the floor of the mouth. Originate on the inferior mental spine of the mandible and insert onto the hyoid bone. Pull the hyoid bone in an anterior and superior direction and widen the pharynx.
- **Genioglossus muscle:** Originates on a short tendon from the superior part of the mental spine of the mandible. Inserts on the body of the hyoid bone and the entire dorsum of the tongue. This fan-shaped muscle contributes most of the bulk to the tongue muscle, extending from chin to tongue. The genioglossus muscle depresses the tongue; it creates a central furrow or groove when acting bilaterally. "Wags" or deviates the tongue when acting unilaterally.

Clinical Relevance: Plastic surgeons consider neck contour the "cornerstone" of the face-lift.[4] That is, landmarks establishing a youthful appearance include delineation of the edge of the mandible and chin, a well-defined cervicomental angle, and visible laryngeal cartilage and SCM muscles.[5] The thyroid cartilage constitutes the most prominent structure on the ventromedial neck.

Features that aging produces include laxity of the soft tissues on the ventral neck and loss of the cervicomental angle.[6] This can occur due to loss of skin elasticity and deterioration of skin quality, loss of tone in the platysma muscle, and accumulation of submental (subplatysmal) fat. Ordinarily, the procedure of choice is cervicofacial rhytidectomy. However, cervicofacial rhytidectomy poses unacceptable risks for some patients, leading to a range of alternate approaches. Thus, one must weigh the risk of complications from more invasive procedures against the possibility of providing only marginal results from less invasive methods.[7] A novel technique that creates a "corset" of the anterior digastric muscles draws the two together and anchors them onto the mylohyoid (i.e., the muscle that creates the "floor" of the mouth), producing striking changes in appearance.[8]

"Beauty" Tip: Performing the yoga posture known as the "Lion Pose", or Simhasana, strengthens many soft tissues involved in maintaining a more youthful cervicomental angle. It activates the platysma and genioglossus when contracting the superficial neck and upper body along with markedly protruding the tongue. To identify the changes this pose causes in the submental tissues, perform the pose and palpate the submental region. You will find a furrow appear beneath the mandible, capable of countering submental tissue sag with regular practice.

Flabby facial and cervical musculature can cause more than aesthetic problems. For sleep apnea patients, excessive relaxation of the genioglossus and geniohyoid muscles during REM sleep has been implicated in obstructive sleep apnea. Treatment at CV 23 with acupuncture and related techniques may improve muscle tone throughout the day and night. Patients can be taught to perform the lion pose (i.e., the forementioned yoga asana) to improve muscle tone in the neck and throat.

Deglutition disorders may arise from impaired action of the geniohyoid, mylohyoid, and digastric muscles that need to act in concert to escort food from the mouth into the pharynx. In cases of nerve entrapment or history of trauma, freeing fascia of the ventral neck reduces pressure on nerves such as fibers from C1 that travel with the hypoglossal nerve to the geniohyoid. Acupuncture and related techniques may then improve nerve communication and muscular coordination, thereby reducing symptoms of dysphagia.

"Pharyngocise" to Improve Swallowing Function: Patients who receive external beam radiotherapy for oropharyngeal cancer are at risk of developing swallowing dysfunction from deep tissue fibrosis.[9] Considering the concomitant problems of dry mouth (xerostomia), mucositis, and edema, patients avoid swallowing even more. In order to counter disuse atrophy, patients who perform swallowing exercises reduce the occurrence of dysphagia-related complications. Research suggests that muscles involved in swallowing, i.e., the genioglossus, hyoglossus, and mylohyoid, deteriorate less with pharyngocise; functional swallowing, mouth opening, salivation rate, and chemosensory acuity are maintained better in patients who performed pharyngocise than those who do not.

Nerves

- **Mylohyoid nerve (CN V_3):** Innervates the mylohyoid muscle.
- **C1, via the hypoglossal nerve:** Innervates the geniohyoid muscle.
- **Hypoglossal nerve (CN XII):** Supplies all of the tongue muscles except for the palatoglossus muscle.
- **Cervical branch of the facial nerve (CN VII):** Innervates the platysma muscle.

Clinical Relevance: The nerves supplying sensation and motor function to the tissues at and near CV 23 participate in defining the cervicomental angle aesthetically as well as producing speech and deglutition functionally. Neuromodulation applied to this area by means of acupuncture and related techniques along

Figure 13-54. This cross-section views CV 23 from the inside, just cranial to where a needle would enter the skin. Note the proximity of CV 23 to the mylohyoid raphe, i.e., the section of tissue that connects the right and left mylohyoid muscles. This area tends to sag in the aging neck, calling for a "corset" of juxtaposed anterior digastric muscles, as is done in certain surgical approaches.

with active, intentional, contraction of local structures, helps facilitate recovery and improves appearance. Treatments called the "acupuncture face lift" work by relaxing muscles that create wrinkles, toning tissues that allow sag, improving circulation and lymphatic drainage, and balancing nerve function for proper proprioception and reduced tension. The acupuncture face lift need not require adopting belief systems as some may claim, insisting that practitioners be "certified" to perform the treatment. Instead, tailor the approach to the individual's face. Identify, by means of observation and light palpation, areas of tension and those requiring toning. Consider introducing laser therapy and massage for in-clinic and home treatment, respectively.

Branches of the caudal division of the mandibular nerve (CN V_3) include the lingual, inferior alveolar, and auriculotemporal nerves.[10] These nerves transmit taste sensation and provide motor supply for mastication, salivation, and speech. Variations in branching patterns can cause unexpected inadequacy of anesthesia from local nerve blocks. In the vicinity of CV 23, communicating branches may link the mylohyoid and lingual nerves. Failure to block all nerve supplying an area allows sensation to continue.

Unilateral, extracranial injury of the hypoglossal nerve results in deviation of the tongue to the damaged side because it removes the protrusive action of the ipsilateral genioglossus muscle that, when bilaterally activated, pushes the tongue straight out.

Vessels

- **Lingual artery:** Arises from the external carotid artery. Branches into 1) the dorsal lingual arteries, which provide circulation to the posterior part of the tongue, and which send tonsillar branches to the palatine tonsils; 2) the deep lingual arteries, which supply the anterior portion of the tongue, and 3) the sublingual arteries, which provide circulation to the sublingual salivary glands and the mouth floor. The only lingual arterial branches which communicate with each other are the dorsal lingual arteries, which do so near the tongue tip. The other lingual artery branches cannot communicate with each other because the fibrous lingual septum prevents them from doing so.
- **Lingual vein:** Tributaries of the lingual vein are the dorsal lingual veins, which accompany the lingual artery, and the deep lingual veins, which begin at the tip of the tongue and course alongside the lingual frenulum until they join the sublingual vein The deep lingual veins are visible through the mucosa on the underside of the tongue. Ultimately, all of the venous drainage of the tongue empties into the internal jugular vein.

Clinical Relevance: Muscles, skin, fascia, and nerves that participate in speech, swallowing, and facial features require sufficient circulation to maintain healthy tissue. Acupuncture and related techniques improve local circulation and tissue repair.

Indications and Potential Point Combinations

- **Glossitis, glossalgia, problems moving the tongue:** CV 23, CV 22, ST 9, LI 18, SI 17.
- **Aphonia, laryngitis, pharyngitis, tonsillitis:** CV 23, CV 22, ST 9, LU 7, LI 4, BL 10.
- **Dry mouth or excessive thirst, hypersalivation (ptyalism), sialorrhea:** CV 23, CV 22, ST 6, ST 7, SI 17, SI 19, ST 36.
- **Cough:** CV 23, CV 22, LU 2, LU 5, BL 12, BL 13.
- **Thyroid, swallowing, and throat problems:** CV 22, CV 23, ST 9, LI 4. (See Figure 13-51C.)
- **Acupuncture "Face Lift":** CV 23, BL 2, GB 1, Yintang (GV 24.5), LI 4, LU 7, GV 20. Add local points as indicated by the individual's unique presentation and aging changes.

Evidence-Based Applications

- A case series indicated that LU 5 and CV 23 effectively treated **pseudobulbar paralysis.**[1]
- Tactile stimulation of the cervical skin triggers strap muscle contraction in dogs via a reflex arc. Somatic afferent stimulation of cervical cutaneous nerves through acupuncture may bolster glottic closure and restore **deglutition.**[2]
- The most frequently chosen acupuncture points for rehabilitation of **aphasia after stroke** include CV 23, Jinjin, Yuye, HT 5, GB 20, PC 6, GV 20, SP 6, GV 15, and scalp acupuncture points Nos. 1, 2, and 3 in the language sections.[11]
- Acupressure applied to CV 23 and TH 17 weekly for four weeks improved salivary flow rates and reduced thirst intensity in patients receiving hemodialysis who often complain of **dry mouth and excessive thirst.**[12]

CV 24

Cheng Jiang "Sauce Receptacle"

At the midline of the chin, in a groove called the mentolabial sulcus below the lower lip.

Muscles

- **Right and left mentalis muscles:** Ascend to the chin from the mandible and raise the chin as when one expresses doubt.
- **Right and left depressor labii inferioris muscles:** Originate on the mandible, lateral to the mentalis muscles, and merge with each other as well as the orbicularis oris muscle. Draw the lower lip in an inferior and lateral direction, as in the expression of impatience.
- **Orbicularis oris muscle:** The sphincter of the mouth, works to close the mouth. Important during speech. Works with the tongue to hold food between the teeth during chewing.

Clinical Relevance: Fibers from the muscles of the chin intermingle at their borders.[3] This finding emphasizes the need for a regional approach to muscle dysfunction affecting this region. Thus, consider acupressure, acupuncture, and laser therapy not only at CV 24, but also surrounding locales.

Failed augmentation mentoplasty sometimes leads to mentalis muscle dysfunction.[4] This results in dimpling of the skin over the chin and ptosis of soft tissue. Acupuncture and related techniques applied to CV 24 and other regional points elevate tissue health and may restore a more normal appearance.

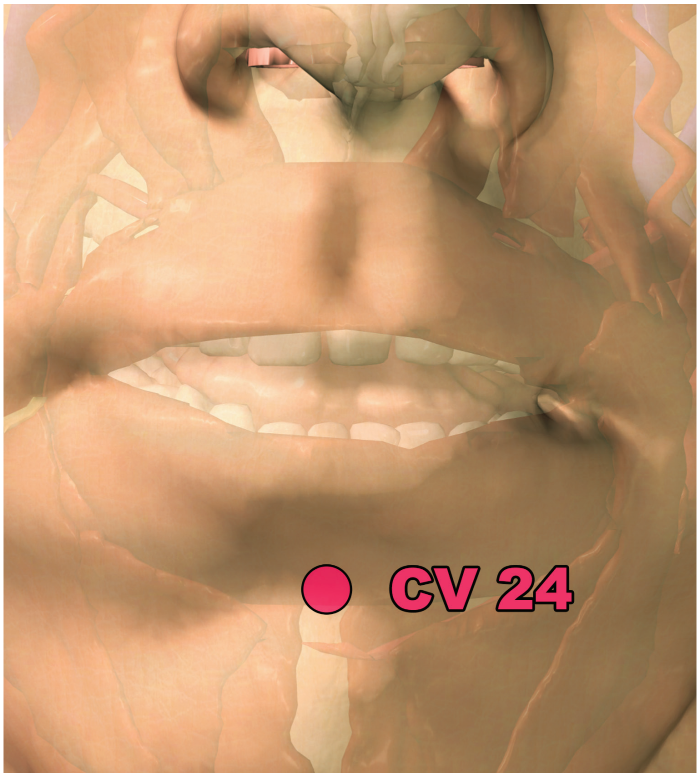

Figure 13-55A. CV 24, "Sauce Receptacle", resides in a depression called the mentolabial sulcus, where sauce or saliva could accumulate in a patient with facial paralysis or oral dysfunction; hence the name.

Nerves

- **Right and left mental nerves:** Terminal branches of the inferior alveolar nerve (from CN V_3). Emerge from the mandibular canal through the mental foramen (see Figure 13-55C). Supply sensation to the skin of the chin, the lower lip, and the lower lip mucosa.
- Right and left marginal mandibular branches of facial nerve (CN VII): Provide motor control to the risorius muscle and to muscles of the lower lip and chin.

Clinical Relevance: Clinical conditions such as sialorrhea (excess salivation) or incompetence of the oral sphincter from facial nerve paralysis could cause "dribbling", i.e., the accumulation of fluid at this point. CV 24 receives innervation from bilateral facial nerve branches supplying the orbicularis oris (i.e., the buccal branch of the facial nerve, CN VII) and the mentalis muscle (via the marginal mandibular branch of CN VII). This explains its value for facial nerve paralysis or injury. Buccal branches from the facial nerve join with filaments from the buccinator branch of the mandibular nerve (CN V_3) and assist with mastication. The mandibular branch of the facial nerve communicates with the mental branch of the inferior alveolar nerve (CN V_3), arguing for the relevance of CV 24 in dental analgesia. In dental anesthesia, Inferior alveolar nerve block is employed in order to numb the lower lip, teeth, and gingivae of the mandible. As such, neuromodulation of the same nerve by means of acupuncture and related techniques may also in producing analgesia.

Acupuncture at CV 24 blunts or eliminates severe gag reflex during dental procedures. This suggests that treatment at CV 24 neuromodulates cranial nerve reflexes. The gag reflex starts with either somatic or psychogenic stimuli. Somatic sites associated with gagging vary but often include the lateral border of the tongue and places on the palate. Psychogenic gagging, mediated by supraspinal centers, can occur in susceptible individuals at merely the thought of dental treatment. The mechanism by which nerves supplying CV 24 aid in controlling the gag reflex likely involves neuromodulation of reflexes between cranial nerves V (trigeminal), XI (glossopharyngeal), and X (vagus). In addition, beta-endorphin release confers anti-emetic effects, thereby reducing the nausea component of the gag reflex.

Vessels

- **Anastomosis between branches of right and left inferior labial arteries:** Branches of the facial arteries anastomose with each other and with the superior labial arteries to encircle the oral cavity.
- **Anastomosis between branches of the mental arteries:** Terminal branches of the inferior alveolar arteries emerge from the mental foramen to supply the facial muscles and chin skin.
- **Anastomosis of the right and left inferior labial veins:** These tributaries of the facial vein drain the lower lip area.
- **Anastomosis of right and left submental veins:** The submental veins drain the chin and merge with the facial vein.

Clinical Relevance: CV 24 relates to the inferior labial and horizontal labiomental artery. Both vessels ordinarily branch off of the facial artery.[5] Vertical labiomental arterial branches from the submental artery converge with descending branches from

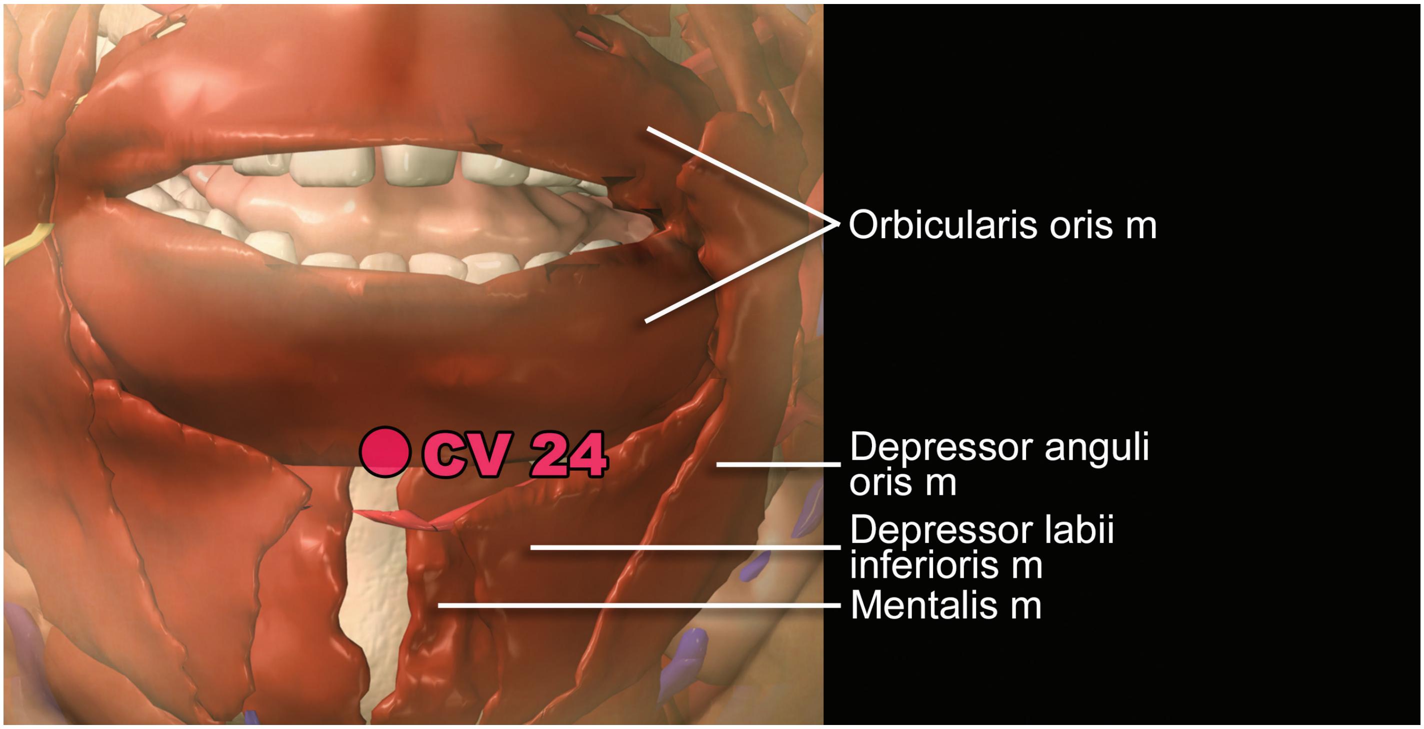

Figure 13-55B. This image reveals the way in which CV 24 denotes the intersection of the lip and chin. It also illustrates how the vessel inferior to CV 24 emerges from behind the depressor labii inferior muscle. This suggests that it may be the horizontal labiomental artery instead of the inferior labial artery.[14] However, facial vascularization varies between and even within individuals from right to left sides. According to some, symmetrical facial vasculature may not exist.[15] The horizontal labiomental artery is rarely mentioned in anatomical descriptions of lower lip and chin anatomy; it could be considered by some authors to be the inferior labial artery, destined to terminate in a "T" at about the level of CV 24 where it branches to supply the lower lip.[16]

the inferior labial artery. Considering the anastomoses between arteries and vessels at this site, CV 24 represents an important locus for potentially improving circulation to the chin and lower lip.

Variations in blood supply to the lips pose challenges to plastic surgeons planning reconstruction. Should a procedure iatrogenically compromise circulation, laser therapy, acupuncture, and massage may aid in restoring proper blood flow to the site.

A condition known as a "prominent inferior labial artery" denotes the presence of a pulsating papule in the lower vermilion border, one or two centimeters from the labial commissure (corner of the mouth). While it may resemble a tumor, it can represent a tortuous segment of the inferior labial artery.[6]

Indications and Potential Point Combinations

- **Coma, stroke, with difficulty speaking:** CV 24, ST 4, CV 23.
- **Facial nerve paralysis affecting function of the mouth and lips:** CV 24, ST 4, ST 6, TH 17.
- **Dental pain, lower arcade:** CV 24, ST 6, LI 4, LU 7.
- **Gingivitis, oral ulcers:** CV 24, ST 7, ST 6, LI 4.
- **Trismus:** CV 26, ST 6, ST 7, GB 3, GB 4, tender trigger points in the temporalis and masseter muscles.
- **Sialorrhea:** CV 24, ST 4, ST 7.
- **TMJ pain:** CV 24, GB 3, GB 2, TH 21, SI 19, tender trigger points in the temporalis, masseter muscle, trapezius, and cervical strap muscles. Integrate laser therapy and massage.
- **Gag reflex:** CV 24,[7] PC 6,[8] auricular acupuncture points.[9]

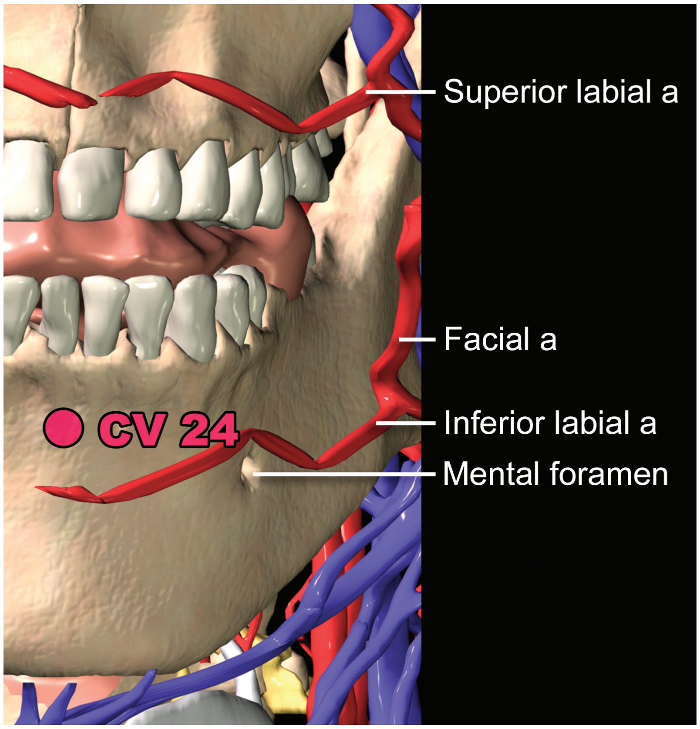

Figure 13-55C. CV 24 relates to the inferior labial and, if present, the horizontal labiomental artery, both usually offshoots of the facial artery.[17] Vertical labiomental arterial branches from the submental artery converge with descending branches from the inferior labial artery. Considering the rich anastomoses at CV 24, circulation to the chin and lower lip can improve following treatment at this site.

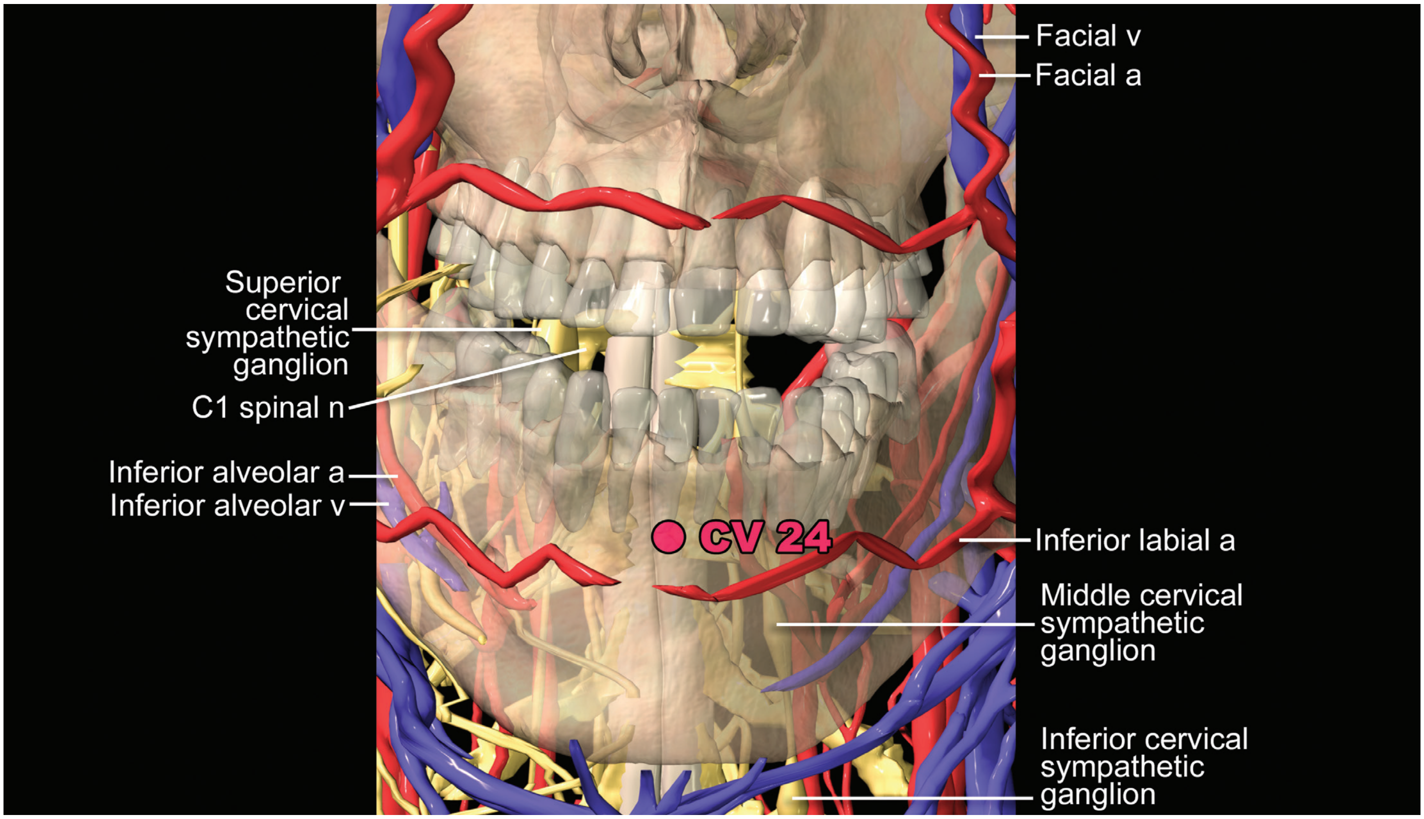

Facial v
Facial a

C1 spinal n
Inferior alveolar a
Inferior alveolar v
CV 24
Inferior labial a
Middle cervical sympathetic ganglion
Inferior cervical sympathetic ganglion

Figure 13-55D. This view provides an "inside view" of CV 24 in relation to the roots of the lower incisor teeth. It also shows anatomical features not often seen in a frontal view, including the three cervical sympathetic ganglia, the upper cervical spinal cord, and various vessels. In this depiction, the inferior alveolar vessels end where that branching would have taken place. The inferior alveolar artery and vein normally divide into two branches, the incisor and mental branches, proximal to the mental foramen at the first premolar tooth. Although not shown, the inferior alveolar nerve accompanies its vascular companions, giving off the mental nerve that emerges with the vessels through the mental foramen to supply the chin.

Evidence-Based Applications

- **Reduces gag reflex** during trans-esophageal echocardiography.[1]
- **Controlled severe gag reflex** in patients requiring an upper alginate impression.[10]
- Acupuncture-like transcutaneous nerve stimulation at SP 6, ST 36, LI 4, and CV 24 improves whole saliva production in patients with **radiation-induced xerostomia** in head-and-neck cancer patients treated with radical radiotherapy.[2]
- Treatment of **primary trigeminal neuralgia** with deep needling at ST 7 outperformed superficial needling. Additional points included CV 24, BL 2, ST 2, LI 4, and LR 3.[11]
- "Best", or at least commonly selected, point options for **peripheral facial paralysis** include CV 24, ST 4, ST 7, ST 6, LI 20, SI 18, TH 17, GB 14, ST 2, GB 20, GV 26, Yuyao, and LI 4.[12]
- Neuromodulation at CV 24, ST 4, and ST 3 may benefit patients with **temporomandibular dysfunction** by reducing activity in the temporalis muscle.[13] Inhibitory impulses from activation of CV 24 might also reduce sensory transmission in trigeminal pathways and help patients with **trigeminal neuralgia.**

Figure 13-56. This cross section visually describes the intermingling fibers of the chin, belonging to the mentalis, depressor labii inferioris, and depressor anguli oris muscles. Make a pouting expression with your face to put these structures into motion. Also, note how the long, muscular tendrils of the tongue reach to its root. Finally, find the mylohyoid muscle that associated closely with CV 23 caudal to this level. See how it hugs the inner border of the mandible at its more rostral extend and abuts the submandibular gland at its other end. Might there be a connection between mylohyoid muscle contraction and saliva production? Another somatovisceral connection!

Channel 14:: The Governor Vessel (GV)

The GV channel begins at the anococcygeal junction. It ascends the dorsal midline and travels up and over the calvarium. It then descends the forehead, travels over the nose, and loops around the philtrum, ending at the upper labial frenulum inside the mouth.

The CSVS, i.e., the venous expression of the GV channel, begins in the pelvis, linking the rectal, prostatic, and internal pudendal veins.

GV and CV as "Singular Vessels"

As indicated previously, GV and its ventral counterpart, CV, constitute "singular vessels", i.e., two pathways in the system of eight that relate to unique vascular routes that, by definition, differ from the standard, paired channels of LU, LI, SP, ST, etc.

The venous system that originally defined the GV channel embodies a circulatory system unmatched by any other in the body, ferrying blood from nose to "tail" and back again. That is, instead of draining blood in a one-way direction as outlined by Harvey and demonstrated by systemic veins and arteries, blood within the mostly valveless veins of the GV pathway, within the cerebrospinal venous system (CSVS), ebbs and flows as pressure dictates. Bidirectional flow provides for auto-regulation of intracranial pressure as one changes posture letting more blood in when needed and shunting it out when not. On the flip side, the CSVS allows tumor cells, infection, or emboli to gain direct vascular access to the brain and spine from the pelvis or anywhere along its route.

The veins belonging to GV supply collateral drainage routes in the event of vena caval obstruction. These alternate pathways provide another avenue to the heart for blood return from the pelvic limbs, similar in many ways to collateral vessels on the abdominal wall, paralleling the KI, ST, and SP channels.

The Cerebrospinal Venous System as the GV Channel

By identifying the GV as a singular vessel, early Chinese anatomists may have recognized the interconnectedness of the CSVS centuries, if not millennia, before modern scientists. As Batson (of "Batson's plexus") noted, "It seems incredible that a great functional complex of veins would escape recognition as a system until 1940… In the first decades of the last century, our knowledge of the vertebral veins was developed and then almost forgotten." Similarly, with acupuncture, the energy-meridian concept of the 20th century took acupuncture on a winding detour through metaphysics from which it is only now emerging.

Veins draining pelvic organs blend with those from the spinal system, seen in this cross section as middle sacral vessels.

The Pelvic Portion of the GV Channel and Its Associated Venous Network

GV 1 begins at the anorectal junction where the CSVS is beginning to form from several venous plexuses, including the rectal, vesical, and prostatic (in males) or uterine and vaginal (in females). This means that blood from the genitalia makes its way to the brain, as verified by imaging studies.

GV Venous Network of the Spine

As the GV channel ascends, it morphs the internal and external vertebral venous plexuses and vertebrobasilar veins. The CSVS connects with the azygous (or azygos), hemiazygous (or hemiazygos), and ascending lumbar veins as well. The figure at the top of the following page illustrates the relationship between the azygous vein and posterior intercostal vessels that drain blood from the dorsal body wall. Both the azygous and hemiazygous veins receive blood from the back, depending on the spinal level and whether it is the right or left side, respectively.

Radicular veins follow the dorsal and ventral nerve roots of the spinal cord. They comprise a dynamic reflux-regulating system capable of responding to pressure changes by diameter adjustment. They confer protection against venous “hyperpression” that would negatively affect the spinal cord by producing harmful venous pressure waves. Venous reflux through the radicular veins may also help with selective cooling of the spinal cord, analogous to the way in which dural venous sinuses aid in lowering brain temperature.

GV Venous Network of the Head

At its rostral limit, the GV channel that “descends along the midline of the head to the bridge of the nose”. That is, the superior sagittal sinus links to a nasal emissary vein that emerges through the foramen cecum, an opening near the anterior end of the crista galli. This establishes a connection between the intracranial superior sagittal venous sinus and the extracranial veins of the nasal cavity, although it is not always present in an adult.

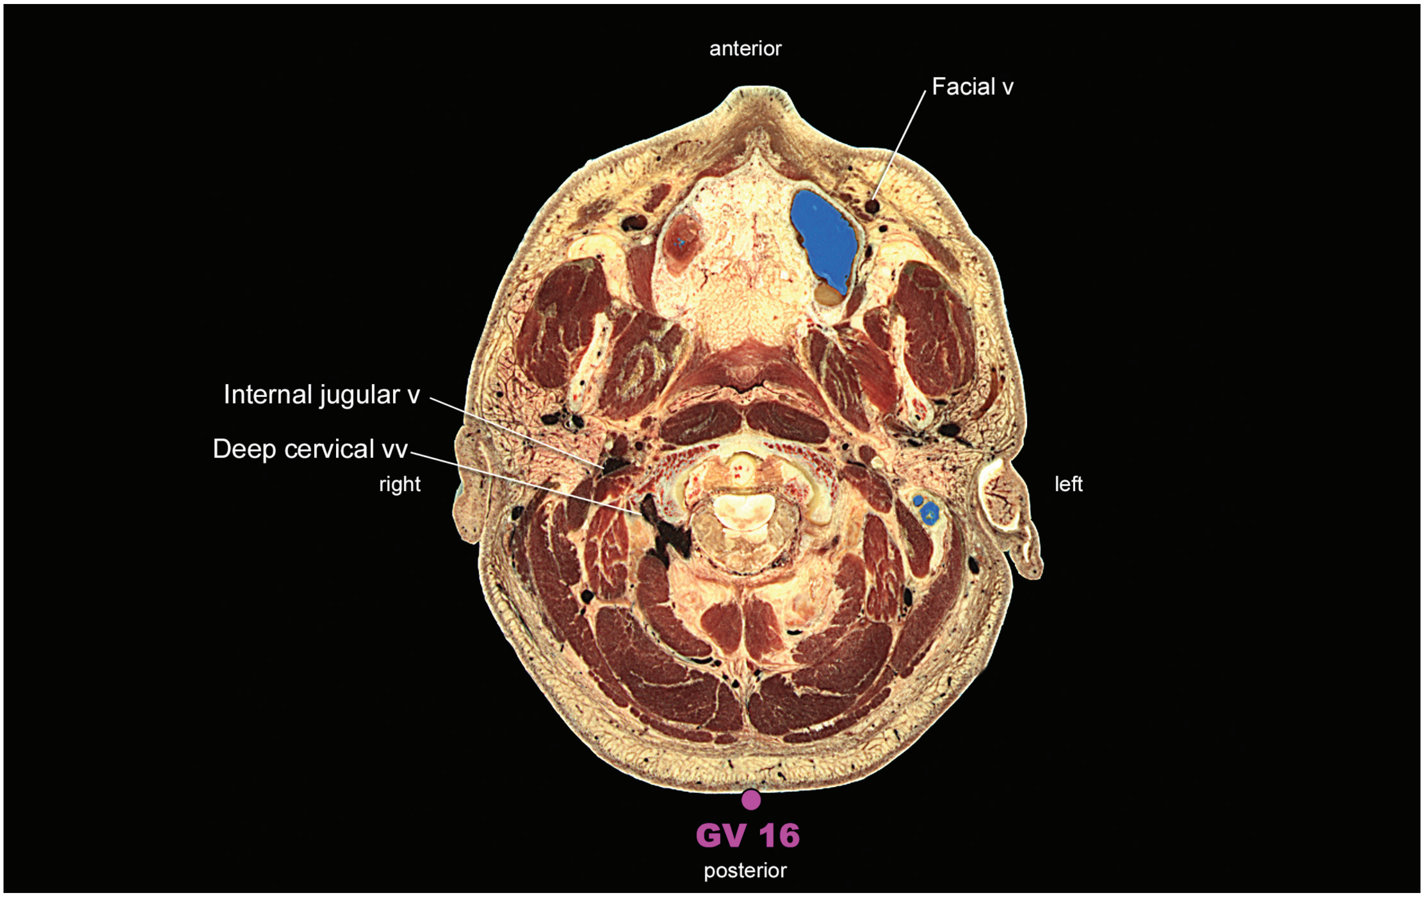
GV 13
posterior

The CSVS includes the basivertebral veins, i.e., vessels that live within the vertebral body and empty into the vertebral venous plexuses. The basivertebral veins are structural analogues of the diploic veins of the skull.

The Neurologic Component of the GV Pathway

Historically, acupuncturists viewed the GV channel as a network of veins as just described. However, modern science shows that neuromodulation at GV points influences nerve function that can influence blood distribution patterns within the CSVS. As such, despite its status as a singular vessel, the GV pathway represents an avenue for impacting brain and spinal cord function at least as much as the blood that bathes them. The preceding images and those that follow explore connections between GV points and the nervous system which are as, if not more, important to the clinical outcome resulting from treating these sites.



anterior
Facial v

right
left
GV 16
posterior

Near GV 16, the vertebral venous plexus blends with the dural venous sinus system. Direct functional communications result from connections between the suboccipital cavernous sinus, condylar veins, and hypoglossal plexus. Communications also take place between the intracranial venous network and veins of the face, scalp, and skull, involving the internal cerebral, facial, ophthalmic, and orbital veins. The cavernous sinus, another aspect of the CSVS, surrounds the pituitary gland. From here, blood drains into the petrosal sinus, sigmoid sinus, and finally into the internal jugular vein.

Just as radicular veins of the back allow heat from the spinal cord to dissipate, the dural sinuses help cool the brain. This may explain why points along the GV channel, including and especially GV 20, feel warm to the touch during headache. Ice and cooling treatments on GV 20 lessen the pain. Brain cooling may aid in treating seizures and stroke as well, emphasizing the value of GV points for these conditions.

GV 1

Chang Qiang "Long Strong"

On the anal triangle, midway between the anus and the tip of the coccyx.

Avoid needling GV 1 and CV 1 in the presence of anogenital warts. Warty tissue is fragile and bleeds easily.[4] Always follow hygienic practice, but especially for palpating and treating CV 1 and GV 1, wear gloves.

Connective Tissues

- **Anococcygeal ligament:** A firm, musculotendinous structure that extends from the posterior aspect of the anal canal to the coccyx and fuses together the insertions of the gluteus muscles, the ischiococcygeus, the pubococcygeus, and the puborectalis muscles.

Clinical Relevance: The anococcygeal ligament displays two layers – a thick ventral layer attached to the presacral fascia and a thin dorsal layer connected to the coccyx and external anal sphincter. Considering its attachments to local blood supply, neuromodulatory techniques applied to GV 1 may improve local circulation and repair of damaged tissue.

Muscles

- **Puborectalis muscle:** Part of the pelvic floor, the puborectalis muscle acts as a sling adjoining the pubic bone to the anorectal ring. Its cranioventral tug creates the "anorectal angle". Composed of skeletal muscle, the puborectalis falls under voluntary control. As an individual contracts the puborectalis, the anorectal angle increases; this keeps stool from moving from its storage site in the sigmoid colon to the rectum for elimination. "Potty training" thus educates one in intentionally contracting the puborectalis until the opportunity for socially acceptable defecation arises. In contrast, squatting reduces the anorectal angle, allowing for easier passage of stool.
- **Pubococcygeus muscle:** A hammock-shaped muscle that stretches from pubis and the anterior obturator fascia to the coccyx and possibly the caudal sacrum. At about GV 1, both right and left pubococcygeus muscles join to form a fibromuscular layer atop the anococcygeal raphe formed by the iliococcygeus muscles.

The pubococcygeus muscle thus serves as part of the pelvic floor and thereby supports pelvic organs, as part of the levator ani muscle group. It functions to control urine flow and participates in parturition and core stability. The pubococcygeus muscle contracts during orgasm. It is activated perineal contraction when one performs Kegel exercises, along with the ischiocavernosus, bulbocavernosus, and cremaster (in men) muscles.

- **External anal sphincter:** Whereas the internal anal sphincter is composed of smooth muscle, the external anal sphincter contains skeletal muscle. This means that external sphincter contraction is under voluntary control, whereas the internal sphincter is not. Nevertheless, the internal anal sphincter contributes to resting tone of the anal canal until it becomes

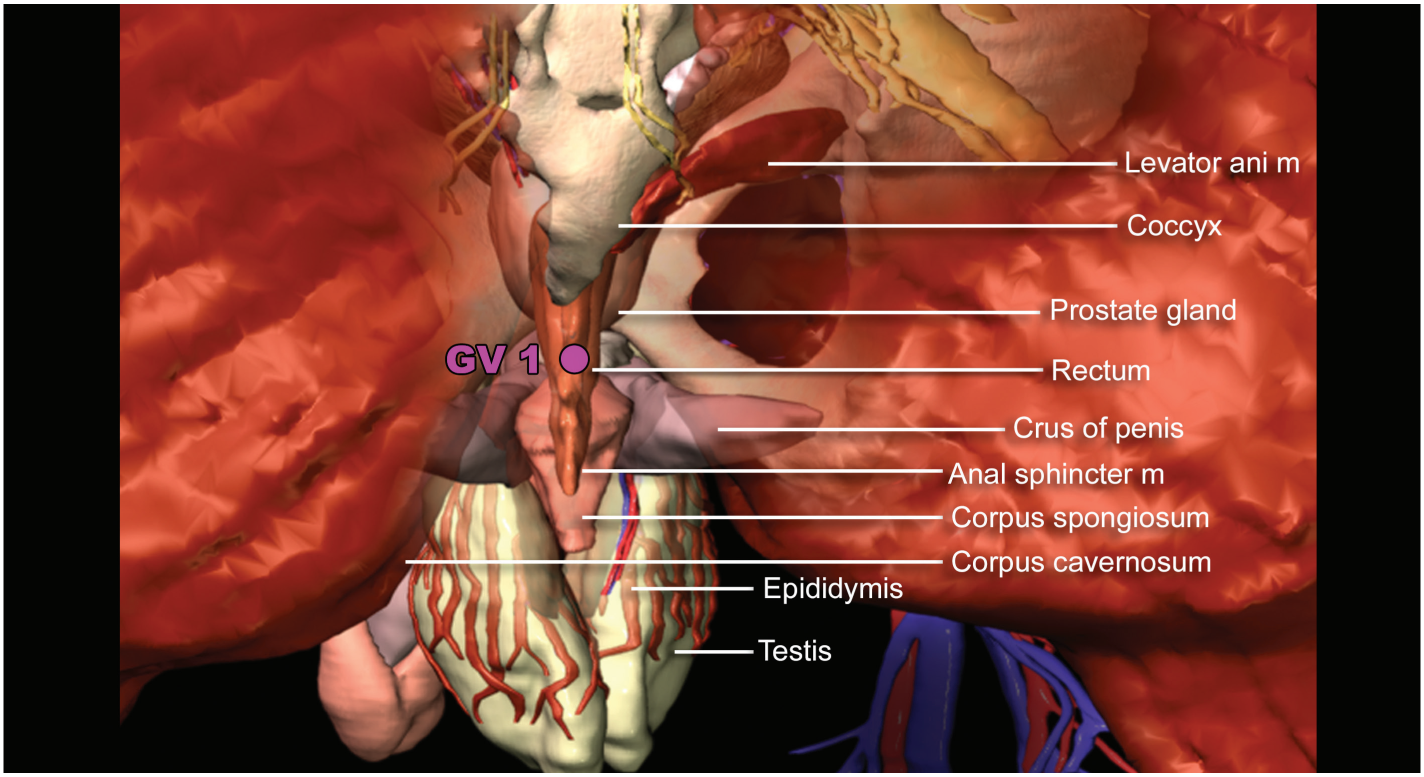

Figure 14-1. GV 1, "Long Strong" appears between the tip of the coccyx and the anus. The name may allude to influence of the point on the function of male genitalia; i.e., the neuromodulatory impact of stimulating GV 1 on reproductive performance. Many colorful, alternate names supplied for GV 1 connote its locus on the tip of the coccyx, below the sacrum. They include: Peg Bone, End Bone, Sacral Bone, End of Sacral Spine, Sacrum Above, Hollow Below the Tailbone, Tail Kingfisher Bone, Tail Maggot Bone, Fish Tail, Tortoise Tail, Tortoise Tail Long Border, Tail Palm, and "That's It!".[14] This dorsal perspective of the sacrum and genitalia peers through semitransparent gluteus maximus muscles to examine the anatomic relationships of GV 1 and nearby structures.

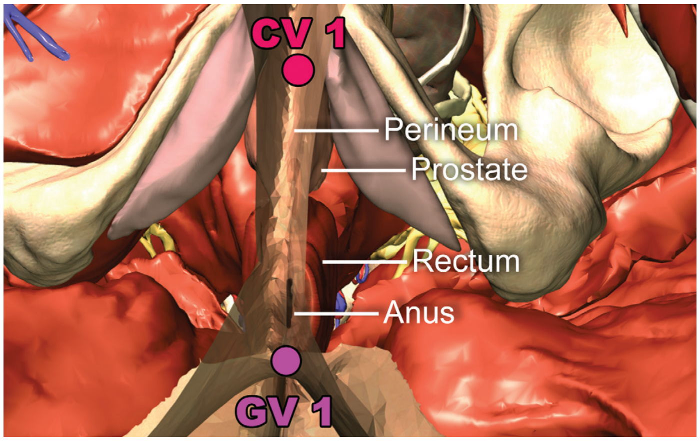

Figure 14-2. The GV and CV channels begin and end on either side of the anus and mouth. This perspective of the perineum depicts the relationship of GV 1 and CV 1 to pelvic structures; it reveals the closer connection of CV 1 to reproductive organs and GV 1 to eliminative.

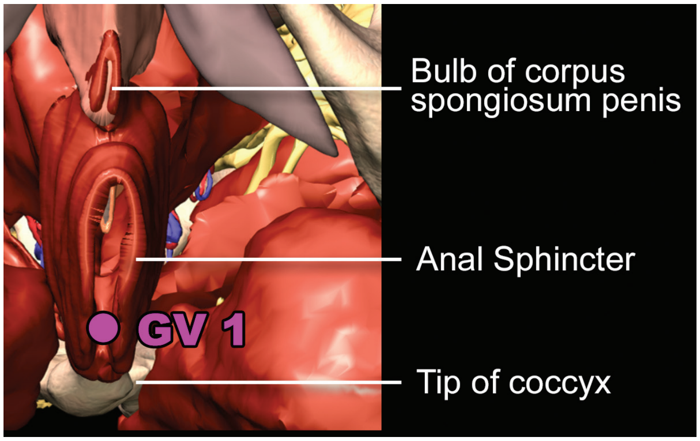

Figure 14-3. GV 1 lands midway between the anus and tip of the coccyx, as shown here. Its proximity to the anal sphincter suggests its value for anal sphincter dysfunction and hemorrhoidal pain. The point is located at the intersection of the S4 and S5 dermatomes, with possible overlap of the Co 1 zone.

time to defecate. The presence of stool normally instigates a rectoanal inhibitory response that relaxes the internal anal sphincter relaxation. Initially, the rectoanal inhibitory response causes external sphincter contraction that pushes stool from the anal canal back to the rectum. When the brain sends signals for defecation to proceed, abdominal muscles contract to raise intra-abdominal pressure. At this time, muscles of the pelvic floor should relax and descend. This allows the anorectal angle to "unbend" and for the relaxation of the external sphincter. Peristalsis begins within the rectum, forcing stool outward.

Clinical Relevance: Structures of the pelvic floor contain striated and smooth muscle, connective tissue, and neurovascular elements. Specifically, the female pelvic floor comprises endopelvic fascia, the levator ani muscle, obturator internus muscle, rectum, urethra, and vagina. A layered pelvic floor that integrates specialized regions of endopelvic fascia creates a three-dimensional support system.

GV 1 relates to muscles of the pelvic floor including the pubococccygeus and puborectalis muscles. (See Figure 14-5.) These associations explain the value of GV 1 for pelvic organ prolapse. Pelvic floor dysfunction in women can cause organ prolapse and stress urinary incontinence in 10% of women.[5] The female pelvic floor comprises three anatomically differentiable compartments with unique structures and functions. Therefore, the symptoms associated with pelvic floor dysfunction depend on the anatomy involved. When dysfunction affects the posterior pelvic floor in the region of GV 1, it may lead to obstructed defecation syndrome (ODS).[6] The pathogenesis of ODS can arise from mucosal prolapse, paradoxical contraction or non-relaxation of the puborectalis muscle, rectocele, intussusception, and enterocele or sigmoidocele. Factors associated with ODS may include changes in anal canal anatomy, degeneration of the internal anal sphincter, and/or atrophy of the external anal sphincter, all of which worsen with aging.

Anismus, otherwise known as dyssynergic defecation, refers to the way in which pelvic floor musculature fails to relax during attempted defecation. It is a functional defecation disorder and constitutes a type of rectal outlet obstruction. Failure of relaxation of the puborectalis muscle, or its paradoxical contraction, can cause anismus, and is worsened by psychological distress. If the puborectalis cannot "let go", it maintains the anorectal angle and inhibits the passage of stool. Paradoxical contraction of the puborectalis may, in fact, make the anorectal angle more acute and further obstruct fecal evacuation.

Patients may complain that they "forgot" how to push stool correctly, but the problem can occur anywhere between brain and anus. If the puborectalis muscle hypertrophies or becomes fibrotic, voluntary control over its function becomes even more challenging. A history of sexual abuse can predispose a person to develop anismus. Parkinson's disease, an extrapyramidal motor disorder, can also lead to anismus.

Over time, failure to fully evacuate stool incurs fecal loading. Eventually, impaction of hard stool follows. Fecoliths may form. In such cases, liquid stool may leak around the retained fecal mass, producing paradoxical diarrhea (called encopresis in children) or fecal leakage in adults.

Biofeedback training may provide some support for patients with anismus, but physical medicine (including rectal retraining) and neuromodulation with acupuncture and related techniques can also aid patients with voiding dysfunction.

Relevance of the pubococcygeus muscle at GV 1: Active contraction of the pubococcygeus muscle is involved in Kegel exercises, designed to strengthen the pelvic floor and support continence of urine. Paroxysmal contraction of the pubococcygeus muscle can lead to vaginismus, similar to the way in which paradoxical contraction of the puborectalis causes anismus.

Myofascial trigger point pathology of the pelvic floor in men: Men who have chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) often exhibit painful trigger point pathology in tissues of the pelvic floor.[7] In addition to pain, these patients may complain of genitourinary dysfunction. Palpation reveals myofascial trigger points in the puborectalis, pubococcygeus, and often the rectus abdominis; pressure on these sites reproduces the pain in over 75% of individuals. Myofascial palpation of trigger points in the external oblique muscles elicit pain in over 80% of patients; pain referral patterns extend to the suprapubic, testicular, and groin regions. Finding a myofascial component of CP/CPPS opens the door to a host of neuromodulatory and manual therapy interventions that may aid patients with this

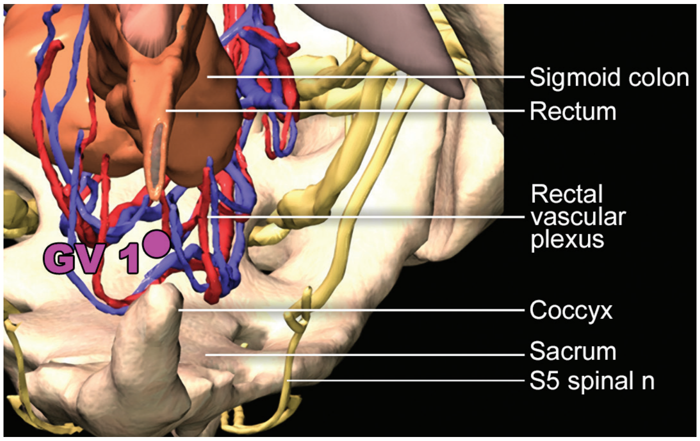

Figure 14-4. The proximity of GV 1 to the plexus of rectal vessels provides a visual display of the reason GV 1 appears in treatment formulae for hemorrhoids.

potentially disabling and frustrating problem that, in many cases, becomes chronic and refractory.

Nerves

- **Anococcygeal nerves from coccygeal plexus (S4, S5 and the coccygeal nerves):** Provide cutaneous sensation to the coccygeal region. The coccygeal plexus forms within the ischiococcygeus muscle from the ventral rami of S4-Co1. It receives input from the sacral sympathetic trunk. The coccygeal plexus supplies the anococcygeal nerve that innervates subcutaneous tissue overlying the dorsal coccyx; some branches pass ventral to the coccyx.[8] These nerves supply the skin of the anococcygeal region and likely contribute to the innervation of the coccygeal ligaments, periosteum, and the sacrospinous ligament and ischiococcygeus muscle.
- **Pudendal nerve (S2-S4):** Innervates perineal structures, providing sensation to the genitalia, and motor control to the perineal muscles, the external urethral sphincter, and the external anal sphincter.
- **Nerves to the levator ani and coccygeus muscles (S3, S4, S5):** Provide motor control to the levator ani and coccygeus muscles.

Clinical Relevance: Coccydynia has several causes; one may stem from neuropathic pain mediated by the coccygeal plexus. Trigger point pathology in the ischiococcygeus muscle may compress the coccygeal plexus and exacerbate coccydynia. Coccydynia frequently worsens with sitting, standing, and even walking. Etiologies include instability of the sacrococcygeal or intercoccygeal joints and/or entrapment neuropathy or traumatic irritation of the coccygeal plexus. While coccygectomy may prove curative, treatment with acupuncture and related techniques as conservative measures should ideally be tried before surgery.

In postmenopausal women, pelvic organ prolapse may impair genital sensation.[9] Treatment of CV 1 and GV 1 with acupuncture and related techniques may aid in the restoration of more normal nerve communication.

Vessels

- **Inferior rectal arteries:** Arise from the internal pudendal artery and supply the distal part of the anal canal and skin.
- **Inferior rectal veins:** Drain the area that the inferior rectal arteries (outlined above) supply.

Clinical Relevance: Engorgement and distention of hemorrhoidal (inferior rectal) vessels may precede thrombosis, presenting as a mass in the vessel associated with persistent and severe pain.[10] Passage of hard stool worsens pain, as does straining to defecate. Eventually, the thrombus may ulcerate through the skin and extrude as a clot. Medical treatment involves bed rest, increased fiber and fluid intake, warm baths, analgesics, and stool softeners. Treatment of GV 1 with acupuncture may not be tolerated or advised; transcutaneous electrical nerve stimulation (TENS) and/or laser would likely be preferred. Ultimately, surgery may be required if the problem does not respond adequately to non-surgical treatment.

Dilation of the inferior rectal vessels causes the familiar condition known as “hemorrhoids”. In severe cases, dearterialization and mucopexy may be required to control bleeding and hemorrhoidal prolapse upon defecation that does not respond to medical therapy.[11] However patients may experience transient rectal pain and tenesmus following surgery. Neuromodulation at GV 1, and GV 2 may aid in their recovery. In some cases after circumferential excisional hemorrhoidectomy, anal stricture may result unless weekly anorectal digital examinations follow the procedure, along with adequate postoperative analgesia.[12]

The degree to which hemorrhoids protrude or interfere with defecation does not necessarily correlate with associated problems with prolapse, including bleeding, itching, pain, and soiling of undergarments.[13]

Indications and Potential Point Combinations

- **Hemorrhoids, hemorrhoidal pain:** GV 1, BL 57.
- **Anal fistula:** GV 1, GV 2.
- **Rectal prolapse:** GV 1, GV 2, BL 31, BL 32, BL 35.
- **Erectile dysfunction:** GV 1, BL 34, BL 31, BL 28, BL 23, GV 20.
- **Prostate problems:** GV 1, GV 2, BL 35.
- **Premature ejaculation:** GV 1, GV 2, BL 35.
- **Fecal incontinence:** GV 1, BL 39, BL 57, BL 35, BL 31, BL 28, BL 27.
- **Coccydynia:** GV 1, GV 2, BL 35.
- **Diarrhea, constipation:** GV 1, ST 36, BL 25, BL 27.

Evidence-Based Applications

- Neuroanatomically, GV 1 may enhance **sexual performance** through its influence on sexual muscle function and its relationship to autonomic centers.[1]
- Acupuncture at GV 1 significantly **reduced colonic motility** and inflammation in rats with colitis, presumably through an opioid pathway.[2]
- Electroacupuncture at GV 1 and BL 57 in a dense disperse stimulation mode (2/100 Hz) reduced pain in patients with **hemorrhoids** in a Chinese clinical trial.[3]

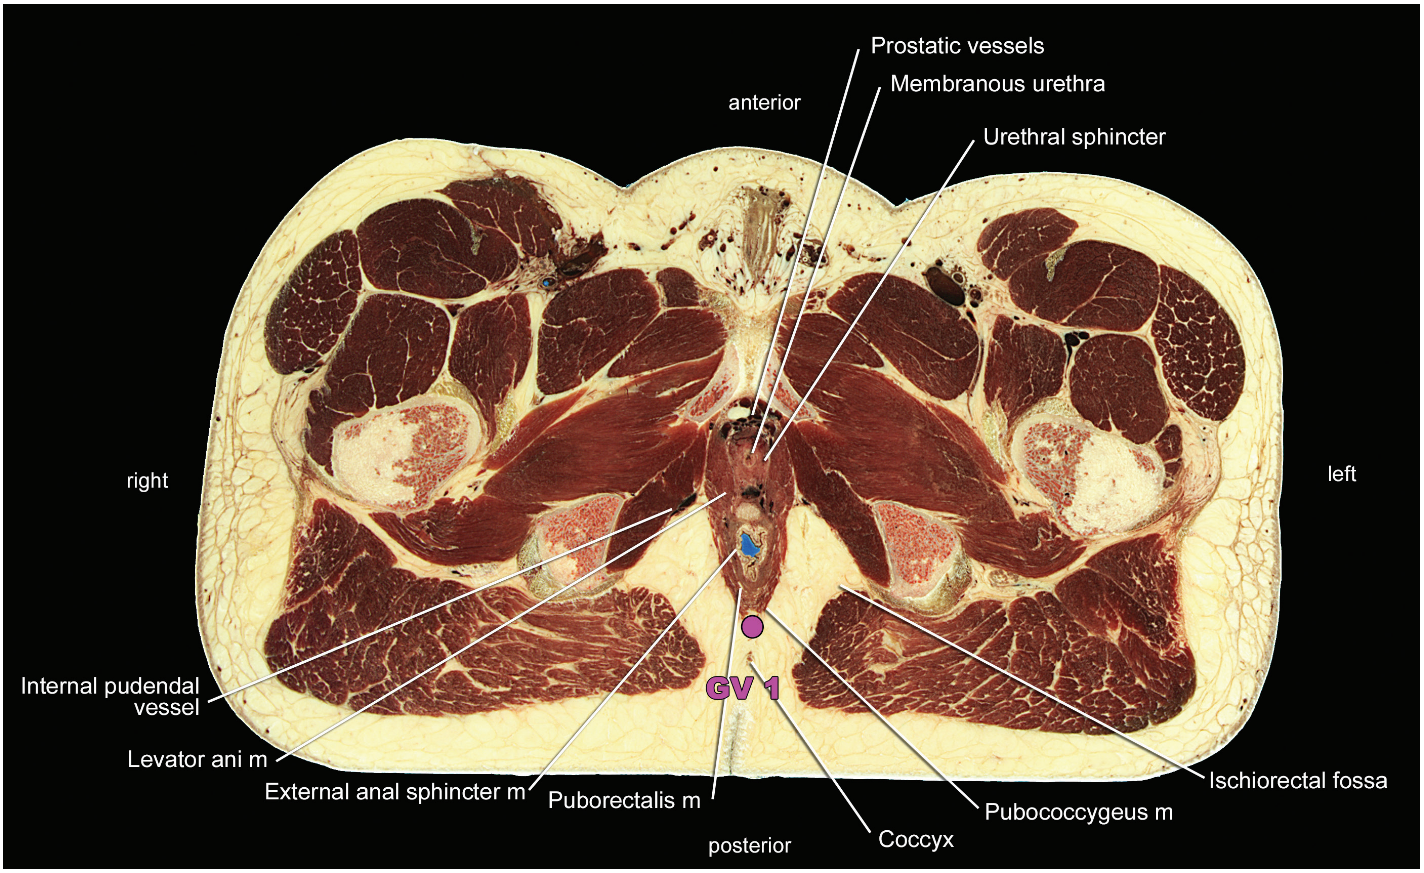

Figure 14-5. GV 1 relates to muscles of the pelvic floor, including the pubococccygeus and puborectalis muscles. Along with the iliococcygeus muscle, these three create the "levator ani" group. Note, too, the presence of prostatic and pudendal vessels, indicating the start of the cerebrospinal venous system (CSVS).

GV 2

Yao Shu "Lumbar Shu"

On the dorsal midline of the sacrum at the sacral hiatus, or sacrococcygeal junction.

Bones

- **Sacral hiatus:** That part of the sacrum with an absence of laminae and spinous processes affecting the S5 vertebra and, sometimes, the S4 vertebra.

Clinical Relevance: As an anesthetic procedure, the sacral hiatus is a landmark for caudal epidural block.[6] The hiatus contains nerve roots from the sacral and coccygeal spinal segments as well as the filum terminale and fibrofatty tissue.

Patients with chronic low back pain and lumbar hypermobility may exhibit tender points on the sacrum such as at GV 2. Manual therapy, acupuncture, and laser therapy may aid in their resolution.[7]

Connective Tissues

- **Anterior and posterior sacrococcygeal ligaments:** Join the apex of the sacrum to the base of the coccyx, reinforcing the joints, in a similar manner as do the anterior and posterior longitudinal ligaments for the superior vertebrae.
- **Filum terminale externum:** The inferior extension of the dura mater below the end of the dural sac at S2, the filum terminale externum attaches to the coccyx and is also known as the coccygeal ligament.

Clinical Relevance: Needling GV 2 first encounters the skin, then the subcutaneous fatty layer and then the superficial dorsal sacrococcygeal ligament, also known as the sacrococcygeal membrane. In order to perform a caudal epidural block, one needs to pass through the membrane and enter the sacral canal with the tip of a hypodermic needle.[8] Acupuncture needling need not enter the canal so deeply.

Nerves

- **Coccygeal nerves, as part of the coccygeal plexus (which include S4 and S5):** Supply the skin near the coccyx, the coccygeus muscle, part of the levator ani muscle, and the sacrococcygeal joint. Anococcygeal nerves emanate from the coccygeal plexus, pierce the sacrotuberous ligament, and provide cutaneous sensation to the coccygeal region.

Clinical Relevance: The sacral hiatus at GV 2 provides an anatomic site where anesthesiologists can reliably and effectively block sacral nerves. This caudal epidural block provides anesthesia for obstetrical and orthopedic procedures.[9]

Invasive sacral neuromodulation with electrode implantation has been used for intractable pelvic pain, anorectal discomfort, fecal incontinence, and irritable bowel syndrome. However, the procedure requires anesthesia; also, it carries the risk of infection, anaphylaxis,[10] and lead migration.[11] Cryotherapy at GV 2 may aid in alleviating perineal neuralgia and coccydynia, as suggested by successful alleviation of pain through cryoanalgesic techniques.[12] GV 2 needling, laser, and manual therapy provide safe and relatively inexpensive neuromodulation for pain reduction and functional restoration of pelvic organs and their activities.

Acupuncture at GV 2 also impacts the cerebrospinal venous

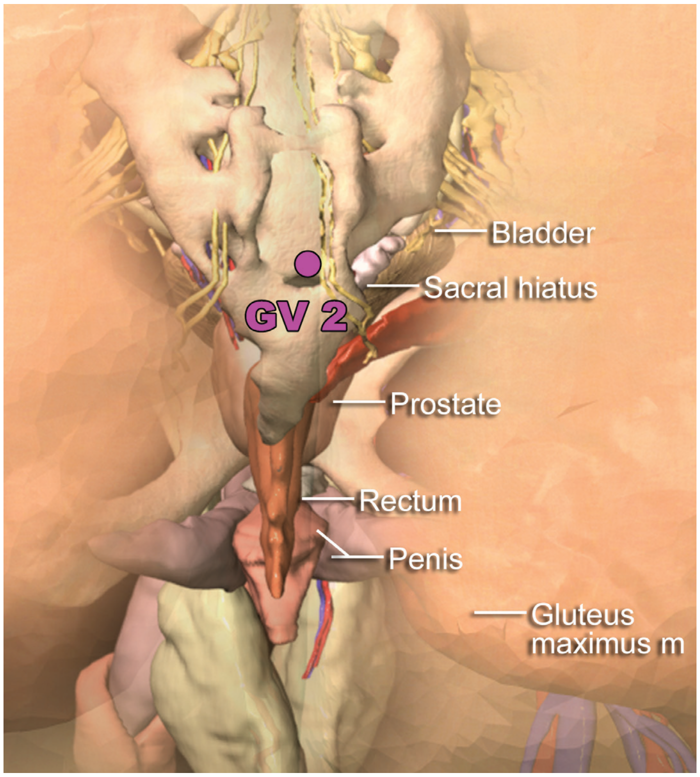

Figure 14-6. Sacral points such as GV 2 offer ample opportunities for neuromodulation of a variety of pelvic organ problems and pain.[15]

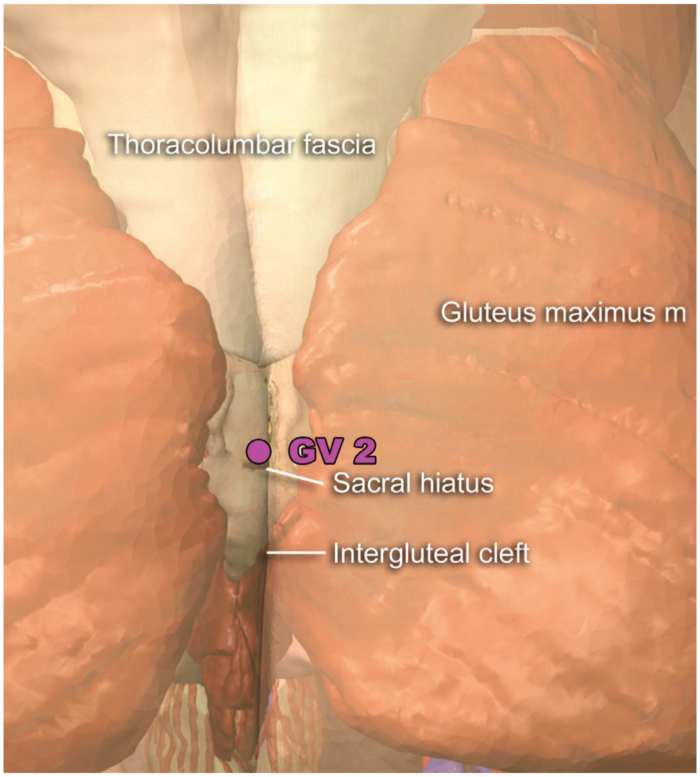

Figure 14-7. Find GV 2 along the intergluteal cleft in the center of the sacral hiatus. Pressure in this region can relieve rectal tenesmus and pain during defecation, thereby facilitating the passage of stool.

system (CSVS). The CSVS connects sacral,pelvic, and prostatic veins with those surrounding the brain and spinal cord. This large-capacity, valveless venous network affords a conduit for bidirectional flow, helping regulate intracranial pressure during postural changes and serving as a drainage ditch that accepts cerebral venous outflow.[13]

Vessels

- **Median (or Middle) sacral artery:** Arises from the dorsal abdominal aorta to provide blood supply to the caudal lumbar vertebrae, sacrum, and coccyx.
- **Median (or Middle) sacral vein:** Accompanies the median sacral artery on the ventral sacrum. The median sacral vein forms a single vein that drains either into the left common iliac vein or the junction of the two iliac veins.

Clinical Relevance: The CSVS, i.e., the cerebrospinal venous system, communicates freely with veins of the sacrum, pelvis, and prostate. This provides functional continuity between the veins of the head, face, pelvis, and body wall, as well as the opportunity for infection, tumor, and emboli to travel broadly and wreak havoc widely.

Indications and Potential Point Combinations

- **Pain in the lower lumbar region, coccyx, sacrum, or kidney:** GV 2, GV 3, GV 4, BL 23, BL 35, BL 60.
- **Tenesmus:** Acupressure/acupuncture at GV 2, GV 3, BL 34, BL 35.
- **Stiffness of the spine:** GV 2, BL 23, GV 4, tender myofascial trigger points, BL 62, SI 3.
- **Urogenital disorders:** GV 2, GV 1, CV 1, BL 31-BL 34, BL 23, KI 3, KI 10, SP 6.
- **Erectile dysfunction:** GV 2 acupressure prior to or during sexual activity.
- **Rectal prolapse:** GV 2, GV 1, BL 31-BL 34.
- **Hemorrhoids:** GV 2, GV 1, BL 35.
- **Seizures, epilepsy:** GV 2,GV 14, GV 20, GV 24.5 (Yintang), BL 10, ST 36, BL 7, BL 8.
- **Fatigue:** GV 2, GV 4, BL 23, GV 20
- **Paraplegia:** GV 2, BL (both inner and outer line) points cranial and caudal to the spinal cord lesion, Bafeng (web spaces between the toes), GV 20.

Evidence-Based Applications

- Electroacupuncture at GV 2, GV 14, and ST 36 markedly **suppressed cortical epileptiform discharges** in rats. Possible mechanisms involved include alterations of opioid, serotonin, and gamma-aminobutyric acid (GABA) levels and recurrent inhibition of the cortex and hippocampus.[1]
- EA at GV 2, GV 14, GV 20, GV 24.5, prevented tissue shrinkage of the dorsal hippocampus, basolateral nucleus of the amygdala, substantia nigra, and perirhinal cortex. EA at ST 36 and SP 6 prevented tissue shrinkage in all of the aforementioned regions except for the dorsal hippocampus. EA to GV 2 + GV 14 + GV 20 + GV 24.5 or ST 36 +SP 6 reduced the cognitive deficits in **pilocarpine-epileptic** rats. Administration of p-chlorophenylalanine, a compound that depletes serotonin, negated the behavioral and some of the histologic changes due to EA. This suggests that the functional recovery exhibited by the rats may have been influenced through serotonergic pathways affected by acupuncture and subsequent neuroprotective benefits.[2]

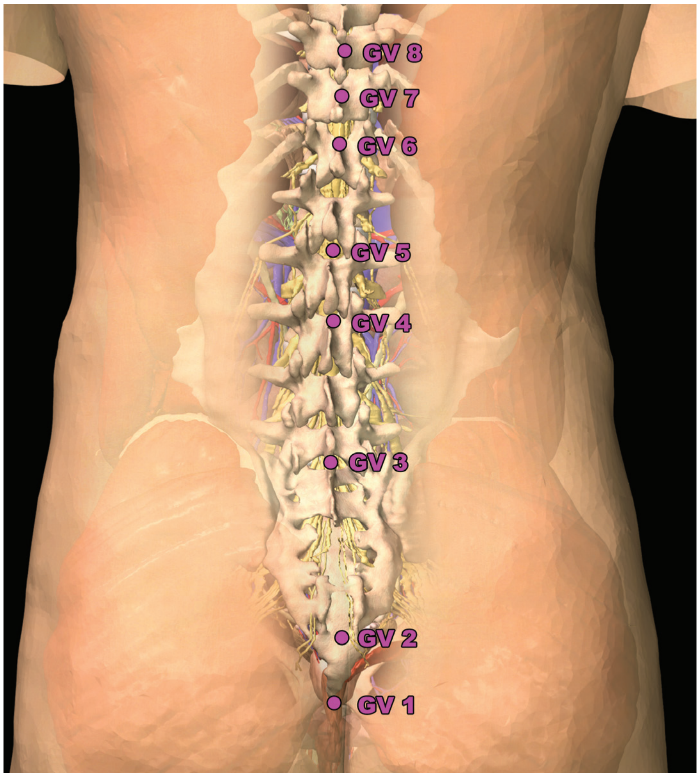

Figure 14-8. The name "Lumbar Transport" for GV 2 connotes its position at the base of the spine.

- Levels **neuronal nitric oxide synthase (nNOS) and nitric oxide (NO)** were consistently higher in acupuncture points and channels that demonstrated low electrical resistance. This study measured NO and nNOS from GV 2 to GV 14, CV 3 to CV 22, BL 36 to BL 57, and PC 2 to PC 6. NO constitutes one of the most important messenger molecules, akin to a neurotransmitter imparting broad influence in interneuronal communication. NO peripheral nervous system and increases sympathetic nervous system activity. Stimulation of sympathetic pathways in the skin lowers electrical resistance. Thus, NO may serve as a messenger for sympathetic nerve activation in dermal neurons. This may mediate acupuncture point functions.[3]
- A randomized, controlled study investigated the effectiveness of electroacupuncture at 2 Hz applied to GV 14, GV 2, and LR 13 for affecting healing of experimentally induced skin flaps in Wistar rats. **Skin flap survival** indices were significantly improved in the electroacupuncture group. This included reduced skin necrosis and preservation of flap integrity.[4]
- Neuromodulation changes the proportion of excitatory and inhibitory signals. This then alters the response of these pathways to physiologic input and adjusts the biologic response to these signals to resolve the dysfunction. Neuromodulation of sacral nerves improves problems related to **voiding dysfunction and fecal incontinence and anorectal sphincter competence.**[5]

GV 3

Yao Yang Guan "Lumbar Yang Gate" "Lumbar Yang Pass"

On the dorsal midline in the depression caudal to the spinous process of L4. Find L4 along a line connecting the highest point of each iliac crest.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae. The ligamentum nuchae embodies the cephalad extension of the supraspinous ligament, acting as an important stabilizer of the cervical spine. Caudal to L4, the supraspinous ligament exhibits less organization and dissolves into the thoracolumbar fascia.[1] In the lumbar spine of the human, the connective tissue of the supraspinous ligament arises from the midline attachments of the dorsal layer of the thoracolumbar fascia as well as the longissimus and multifidus muscles. Dense connective tissue fibers from the thoracolumbar fascia form distinctive bands that cross the midline and then merge with fibers from the other side to form the supraspinous and interspinous ligaments. In the upper thoracic spine, a different set of muscles contributes to midline ligament formation. That is, the trapezius, rhomboideus major, and splenius cervicis meld with deep fascia and in the midline produce the supraspinous ligament.[9]
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. The interspinous ligaments may represent a deep aspect of the thoracolumbar fascia.
- **Thoracolumbar fascia:** An extensive fascial sheet that enclosed the deep muscles of the back, with lateral attachments to the internal oblique and transversus abdominis muscles.

Clinical Relevance: The connective tissue structures outlined above form an integrated Complex that some refer to as the Interspinous-supraspinous-thoracolumbar (IST) ligamentous complex.[2] This complex has been likened to a connective tissue sleeve, or stocking, providing functional as well as anatomic connectivity. That is, the interspinous- supraspinous-thoracolumbar ligamentous complex may anchor major fascial planes of the back to the spinous processes and thereby stabilize the spine.

Structural linkages between the thoracolumbar fascia, multifidus myofascia, supraspinous and interspinous ligaments, ligamentum flavum, and facet joint capsules, suggest opportunities to reduce pain and debility from facet dysfunction by addressing thoracolumbar fascia tension and restriction.

Nerves

- **Dorsal rami of lumbar spinal nerves from L2 to L4:** Innervate the local skin, muscles, and ligaments.

Clinical Relevance: Considering the spinal segmental nerve supply for GV 3 and the somatosomatic as well as somatovisceral reflex connections, neuromodulatory opportunities exist for treating lumbar back pain, paraparesis, sciatic pain, genitourinary conditions, and lower gastrointestinal disorders by means of acupuncture and related techniques.

Vessels

- **Posterior external vertebral venous plexus:** Venous circulation of the spine exists as a dense vertebral venous network that provides drainage for the vertebrae and for epidural and paraspinous tissues, including fat and muscle. The veins comprising this network, or plexus, are thin-walled and valveless. They drain venous blood from the marrow space within the vertebrae and from the capillaries of their cartilaginous endplates. Closely linked internal and external vertebral venous plexuses envelop the interior and exterior spinal column and freely communicate with one another. The internal vertebral venous plexus resides within the vertebral canal while the external plexus resides outside of the canal. Each plexus has anterior and posterior components. The posterior external vertebral venous plexus may receive venous drainage from the vertebral bodies themselves. Veins emanating from the network accompany the spinal nerves as intervertebral veins that exit the intervertebral foramina; these may serve as collateral generators of radicular pain.[3] Communications also exist between the veins of the spinal cord and the vertebral, posterior intercostal, lumbar, and lateral sacral veins.

The veins surrounding the spinal column have profound significance in terms of acupuncture anatomy. According to Kendall, the Nanjing (Difficulty 28) describes the GV channel as beginning "in front of the lowest part of the perineum, and from this area travels side-by-side up the interior part of the back (azygous and hemiazygous, and the ascending lumbar veins) to enter the

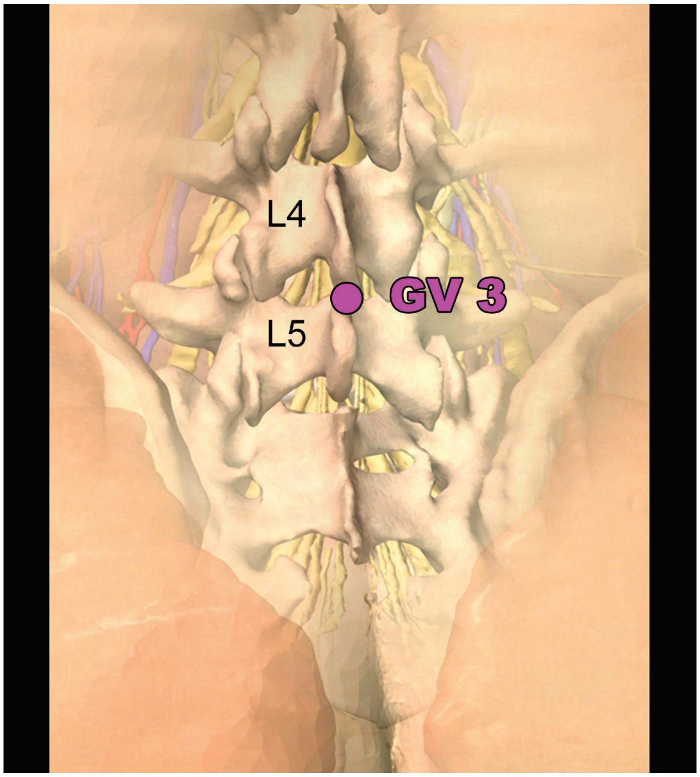

Figure 14-10. GV 3, "Lumbar Yang Gate" refers to this being a portal to neural activity coursing through the vertebral canal. Although the ancient Chinese likely did not perform lumbar punctures to access cerebrospinal fluid, the intervertebral space between L4 and L5 at GV 3 is one site where "spinal taps" are performed. As is visible between the vertebrae, the spinal cord has ended cranial to this level which is now inhabited by the cauda equina.

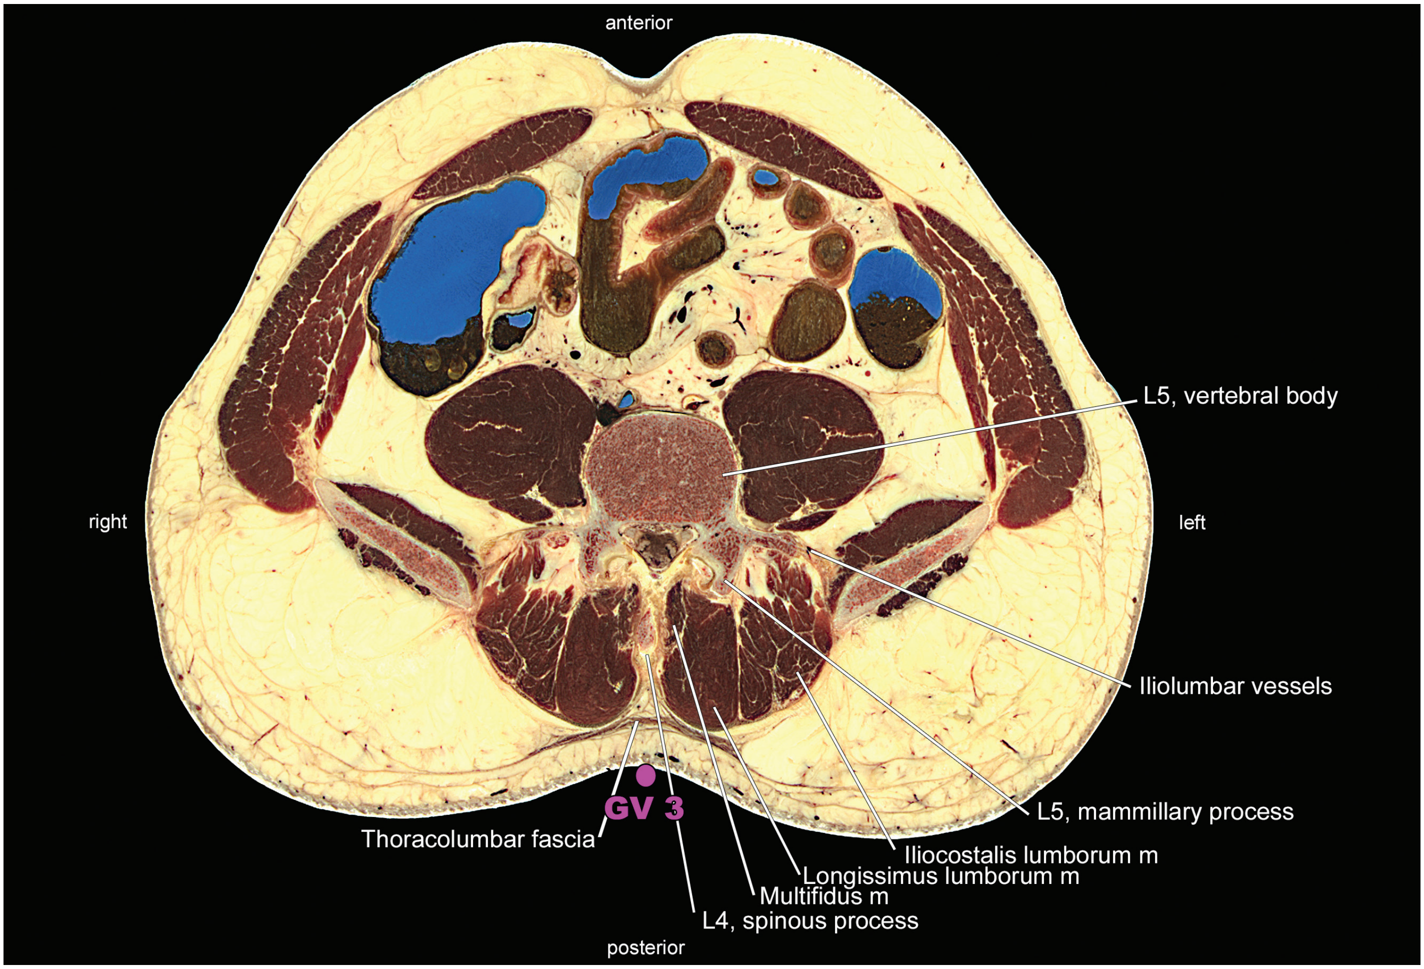

Figure 14-11. Note the heavy investment of connective tissue within and around the paraspinal muscles and how this contrasts with the homogeneity of the hypaxial muscles.

node Fengfu (DU 16 (GV 16)), where it connects with the brain."[6] Considering Deadman's descriptions of the primary pathway, three branches, and luo-connecting vessel of the Governor Vessel channel, the correspondence between the channel and its associated venous pathways becomes quite clear.

From an anatomic perspective, the internal vertebral venous plexus communicates with the occipital and basilar sinuses of the skull, at the foramen magnum (near GV 16). The azygous (or azygos) system of veins mentioned by Kendall drains blood from the posterior walls of the thorax and abdomen. It links the vertebral venous plexuses traversing the thoracic, lumbar, and sacral regions. The ascending lumbar veins arise from the sacral and lumbar veins. At the level of L1 or L2, the right ascending lumbar vein becomes the azygous vein. The azygous vein may also arise from the inferior vena cava or right renal vein. It enters the thorax through the aortic hiatus of the diaphragm and passes along the right side of the spine until it reaches T4, at which point it arches over the root of the right lung to end in the superior vena cava. The azygous vein receives the right subcostal and intercostal veins, the hemiazygous vein, several esophageal, mediastinal, and pericardial veins, as well as the right bronchial vein The left ascending lumbar vein becomes the hemiazygous vein, which exits the abdominal cavity through the left crus of the diaphragm and travels along the left side of the T12 to T8 thoracic vertebrae. At T8, the hemiazygous vein crosses the midline behind the aorta, thoracic duct, and esophagus to join with the azygous vein, into which it empties.

The hemiazygous vein receives the left subcostal vein and the lower four or five intercostal veins, as well as some esophageal and mediastinal veins.

An accessory hemiazygous vein assists the hemiazygous vein in draining structures on the left side. The accessory hemiazogous vein receives tributaries from the 4th through the 8th intercostal veins, and occasionally from the left bronchial veins. The azygous and hemiazygous veins provide one of the main avenues through which venous drainage from the thorax, abdomen, and back can continue in the face of caval obstruction, due to their extensive communications with the superior and inferior venae cavae, ascending lumbar veins, and many tributaries of the inferior vena cava.

- **Dorsal branches of right and left 4th lumbar arteries:** The lumbar arteries arise from the aorta, and embrace their respective vertebrae. Each lumbar artery supplies twigs to its related vertebral body; dorsal branches from each artery also supply the back muscles and spinous process on that vertebra. In addition, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors.[4] Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-homing factors.[5]

Indications and Potential Point Combinations

- **Lumbar pain and sciatica:** GV 3, BL 23, BL 24, local trigger points, GB 30, BL 40, BL 39, BL 60, KI 3.
- **Paresthesias, numbness, or cold feeling in the pelvic limbs:** GV 3, GB 25, BL 23, points associated with the involved neuropathic nerves and spinal cord segments, LR 3.
- **Erectile dysfunction:** GV 3, GV 2, BL 23, LR 5, CV 2, CV 3, GV 20.
- **Genitourinary problems:** GV 3, BL 23, BL 28, KI 3, SP 6, CV 3.

Evidence-Based Applications

- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[7]
- Electroacupuncture at BL 60, BL 54, and GV 3 in rats following experimental **spinal cord contusion** at T8 improved function and spared ventral horn neurons compared to control rats.[8]

Evidence-Based Applications

- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[7]
- Electroacupuncture at BL 60, BL 54, and GV 3 in rats following experimental **spinal cord contusion** at T8 improved function and spared ventral horn neurons compared to control rats.[8]

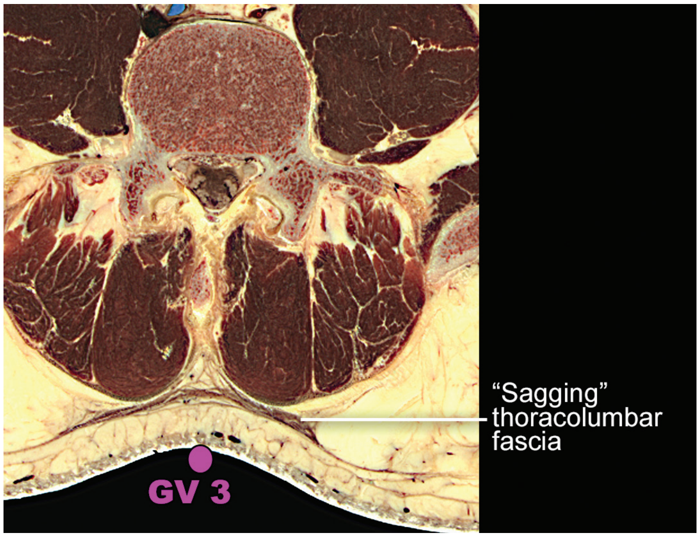

Figure 14-12. This close-up view of the spine at GV 3 reveals “sagging” in the thoracolumbar fascia, possibly indicating chronic spinal instability.[10]

GV 4

Ming Men "Life Gate"

On the dorsal midline, caudal to the spinous process of L2.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae. In the lumbar spine, the connective tissue of the supraspinous ligament arises from the midline attachments of the dorsal layer of the thoracolumbar fascia as well as the longissimus and multifidus muscles. Dense connective tissue fibers from the thoracolumbar fascia form distinctive bands that cross the midline and then merge with fibers from the other side to form the supraspinous and interspinous ligaments.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. The interspinous ligaments may represent an extension of thoracolumbar fascia.
- **Thoracolumbar fascia:** An extensive fascial sheet that encloses the deep muscles of the back, with lateral attachments to the internal oblique and transversus abdominis muscles.

Clinical Relevance: The midline connective tissues can be viewed as an integrated complex, called the "interspinous-supraspinous-thoracolumbar (IST) ligamentous complex".[1] It has been likened to a connective tissue sleeve, or stocking, linking the thoracolumbar fascia to the anterior longitudinal ligament of the spine. This functional connectivity allows the various components to work in an organized manner.

Furthermore, structural linkages between the thoracolumbar fascia, multifidus myofascia, supraspinous and interspinous ligaments, ligamentum flavum, and facet joint capsules, offer opportunities to reduce pain and debility from facet dysfunction by addressing thoracolumbar fascia tension and restriction.

Thoracolumbar fascia, in particular its dorsal (posterior) layer, facilitates load transfer between the spine, pelvis, and legs. Examine the connections it makes with major movers of the torso as shown in Figures 14-15 and 14-16. However, dysfunction within the thoracolumbar fascia potentially places excessive pull on its myriad muscular and osseous attachments, and can cause widespread, debilitating strain and pain. Interspinous locations, including GV points, from sacrum to mid-thorax denote anatomic sites where strain patterns from the right and left sides intersect and where response to treatment may prove valuable in alleviating maladaptive myofascial patterns.

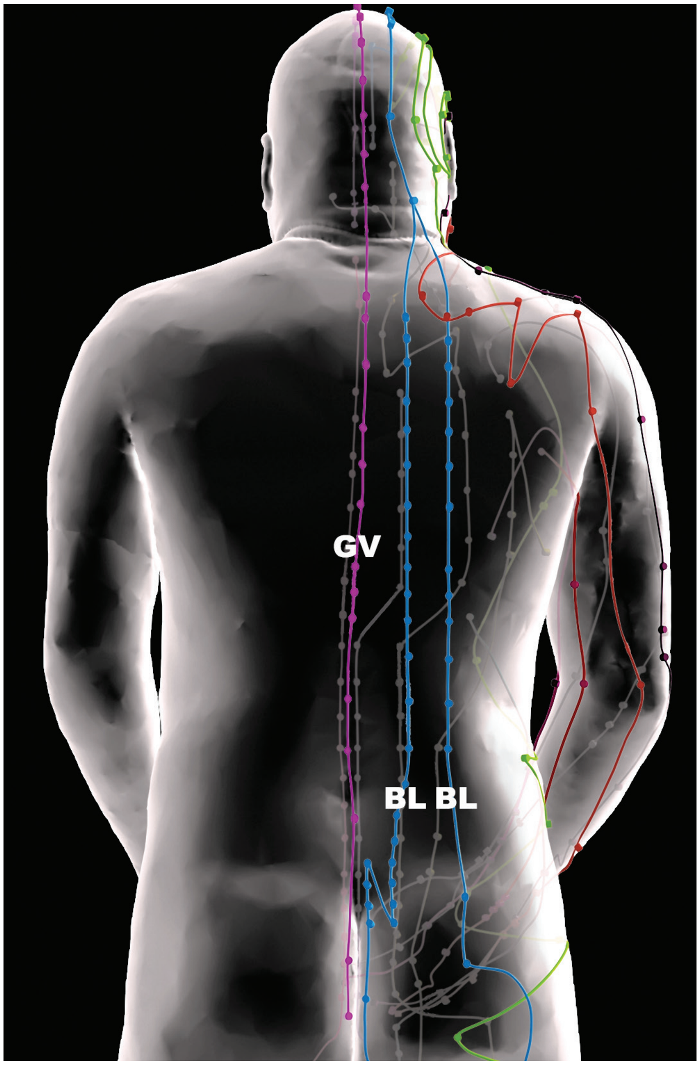

Figure 14-13. Even though the GV line lies directly over the spine, points on the BL channel may confer greater treatment benefit than most GV sites.

Nerves

- **Dorsal rami of lumbar spinal nerves from T12 to L2:** Innervate the local skin, muscles, and ligaments.

Clinical Relevance: Considering the spinal segmental nerve supply for GV 4 and the somatosomatic as well as somatovisceral reflex connections, neuromodulatory opportunities exist for treating lumbar back pain, paraparesis, sciatic pain, genitourinary conditions, kidney problems, and lower gastrointestinal disorders by means of acupuncture and related techniques.

Sensory input from the kidney reaches the T10-T11 levels of the spinal cord, although the network of sympathetic preganglionic neurons actually spans a broader spinal segmental level, possibly extending into the cranial lumbar cord. Spinal cord segments ferrying sympathetic supply to the kidney become important targets for neuromodulation in patients with renal disease and hypertension. That is, neuromodulation of cranial lumbar spinal segments has the potential to reduce spinal cord sensitization and sympathetic overactivation. As such, the points GV 4, BL 23, and BL 52 constitute primary points for renal disease in that they fall within the T10-L2 dermatomes. One might also consider adding GB 25 for renal problems. See Figure 14-16 to view the placement of points in the "kidney tiara".

GV points act on midline anatomy and neuromodulate by means of the medial branch of the dorsal primary ramus of the related spinal nerve. The inner BL line has the capacity to influence both the medial and lateral branches of the dorsal primary rami, while the outer BL line impact predominantly the lateral branch. Even though they may send somatic afferent stimulation through different branches, the end clinical result often overlaps because the sensory fibers reach the same spinal nerves and spinal cord segments.

However, BL points interface with muscle tissue whereas GV

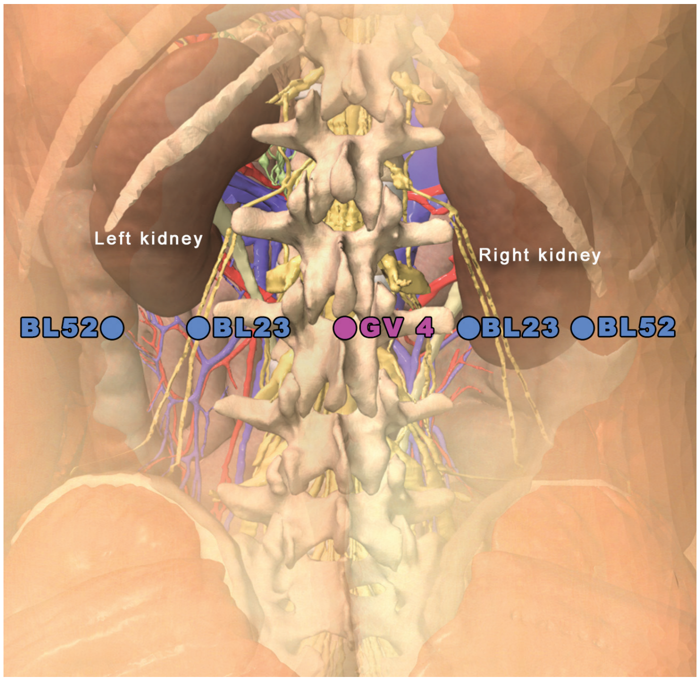

Figure 14-14. GV 4, BL 23, and BL 52 constitute the "kidney tiara"; i.e., a set of points indicated for renal dysfunction. One might also add GB 25 and CV 6.

points in the lumbar region do not. This translates into activating fewer types of nerve endings and mechanoreceptors with GV point stimulation, and less of a neuromodulatory impact than for BL points at the same level. Furthermore, myofascial trigger points are not part of the focus for GV points on the lumbar spine, whereas they are a key element of BL point activation.

A "compromise" point location, denoted by the Huatuojiaji points at each level, 0.5 cun from midline, targets both muscle tissue and potentially both medial and lateral branches of the dorsal primary ramus, depending on the level of the spine receiving treatment. Anatomically, as shown by Figure 14-16, Huatuojiaji points influence the multifidus muscle, i.e., part of the spinalis group, rather than the longissimus or iliocostalis band. Treating back pain effectively requires astute palpation to delineate which muscles, fascial layers, and trigger points are causing problems and targeting needling, manual therapy, and laser treatment to sources of disturbance. In other words, focusing on unaffected or less affected zones other than main problem may confer indirect benefit but leave the largest source of tension and myofascial pathology relatively untouched.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitutes part of the superior vena caval system. The azygous system links various venous segments throughout the thoracic, lumbar, and sacral regions.

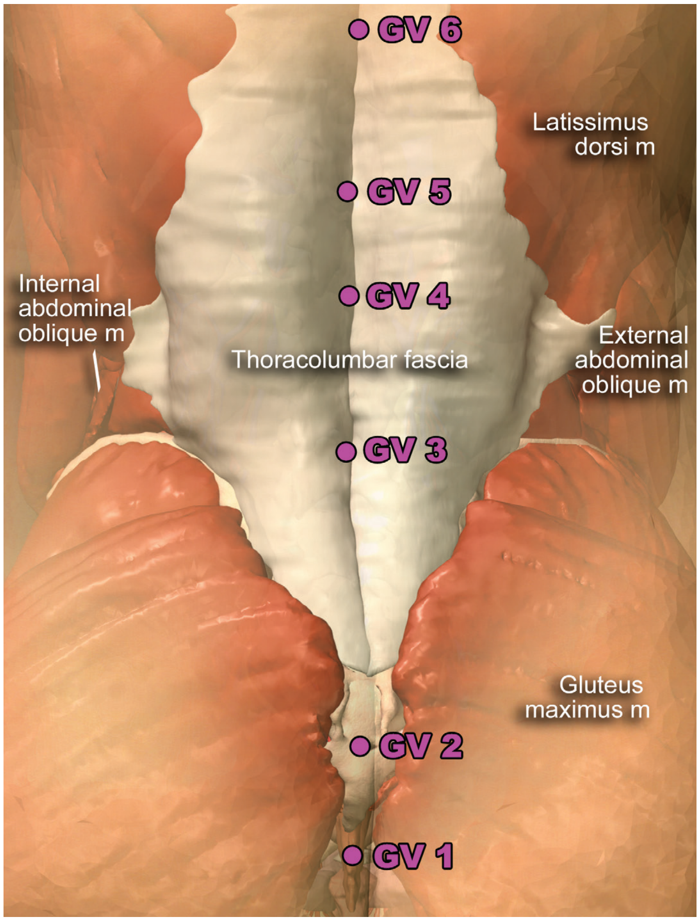

Figure 14-15. GV 4 appears often in formulae for low back pain and stiffness of the spine. This image reveals the point's central location within the broad expanse of the thoracolumbar fascia. This extensive network of connective tissue distributes load, orchestrates movement, and manages spinal stability when functioning properly. If injury should impose maladaptive strain patterns on the thoracolumbar fascia, it may compromise one or more of these functions.

- **Dorsal branches of right and left 2nd lumbar arteries:** The lumbar arteries branch off of the aorta and embrace their respective vertebrae. Each lumbar artery supplies twigs to its vertebral body; dorsal branches from the artery also supply the back muscles and spinous process on that vertebra.

Spinal branches enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bone, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches also supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain

Figure 14-16. The ancient Chinese regarded GV 4, located between the kidneys, as the origin or foundation of life in the individual, hence its descriptive title, "Life Gate". They may have mistakenly attributed reproductive function to the kidneys instead of the adrenal glands, which produce sex hormones. Or, perhaps they were considering the embryologic progenitor of the reproductive system, i.e., the mesonephros, which develops into both genital and renal/urinary tissue. Also note how the acupuncture points GV 4, BL 23, BL 52, and GB 25 comprise the "kidney tiara" and encircle the kidneys. The "kidney tiara" protocol is designed to treat renal disorders and neuromodulate kidney function by means of spinal segmental reflexes.

internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Spinal pain or stiffness:** GV 4, GV 20, BL 23, BL 52, acupuncture to tender trigger points, restricted myofascial bands, BL 60, KI 3.
- **Headache:** GV 4, BL 60, LR 3, LI 4, GV 24.5, GV 20, BL 10.
- **Spinal meningitis:** GV 4, GV 2, GV 14, GV 20.
- **Genitourinary problems:** erectile dysfunction, vaginal discharge uterine bleeding, urethritis, urinary retention: GV 4, BL 23, BL 25, BL 28, BL 31, BL 32, BL 33, BL 34, SP 6, ST 36, KI 3.
- **Kidney problems:** GV 4, BL 23, BL 28, BL 52, GB 25, KI 3.
- **Acupuncture analgesia for the caudal region of the body:** GV 4, GV 2, ST 36, BL 60, GV 20, dense disperse electroacupuncture stimulation applied three spinal cord segments cranial and caudal to the area requiring analgesia.

Evidence-Based Applications

- Neuroanatomically, GV 4 may support sexual performance through its influence on **spinal sympathetic pathways.**[2]
- Acupuncture at CV 3, CV 6, GV 4, BL 23, BL 32, LI 4, ST 36, and KI 3 provided significant improvement in anal continence for patients experiencing **fecal incontinence.**[3]
- Spinal cord stimulation at the L2-3 segments significantly reduced excitatory responses to colorectal distension experimentally applied to rats. These data showed that lumbar spinal cord stimulation afforded neuromodulation of responses generated by lumbosacral spinal neurons in response to noxious mechanical stimulation of the colon. This experiment provides insight into the possible mechanisms of action of acupuncture input at the L2-3 cord for discomfort related to **irritable bowel syndrome** and other colon conditions.[4]
- Spinal cord stimulation modulated the activity of lumbosacral spinal neurons receiving noxious input from the urinary bladder caused by distension, suggesting a mechanism by which acupuncture stimulation reaching the L2-3 spinal cord segments may reduce hypersensitivity and/or the pain from cystitis and other urinary bladder disorders.[5]
- Acupuncture at BL 23, BL 28, and GV 4 or CV 4, CV 6, and SP 6 benefited patients with diurnal symptoms associated with **idiopathic bladder instability.**[6]
- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis.**[7]
- Of the following group of points, 12 were chosen according to the Chinese medical assessment of men with **low quality sperm.**

Following a series of acupuncture treatments, their fertility index increased significantly, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. The acupuncture points from which the 12 were selected included: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[8]

- Acupuncture at GV 4, GV 9, GV 10, GV 11, GV 14, and GV 20 **helped relieve symptoms related to narcotic drug withdrawal**.[9]
- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[10]
- Electroacupuncture at GV 4 in mice **suppressed delayed type hypersensitivity** and appears to involve the pituitary and neuroendocrine system.[11]
- Electroacupuncture at GB 29 and GV 4, applied to ovariectomized rats promoted release of insulin-like growth factor, which may help improve **post-menopausal osteoporosis** problems by increasing bone marrow density in this osteoporosis model, according to a Chinese study.[12]

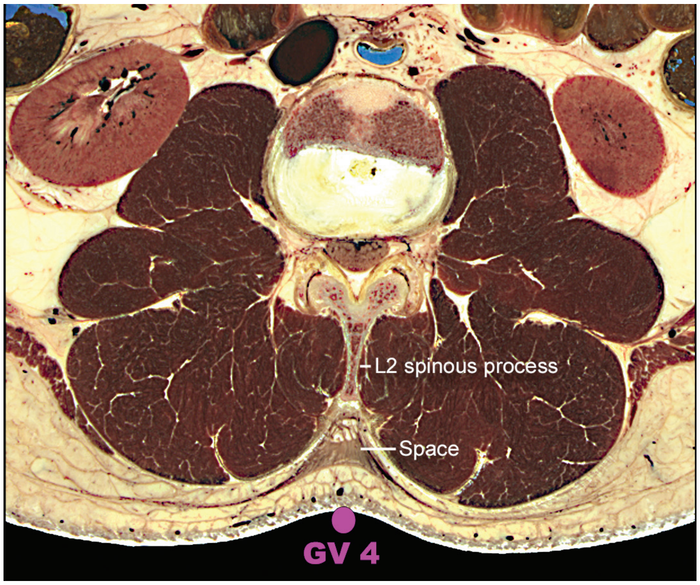

Figure 14-17. Note how a space has appeared deep to GV 4 between the subcutaneous fat and the spinous process of L2. An acupuncture needle entering here would transmit differences in tissue resistance as reaches the cavern. It behooves the practitioner to remain sensitive to palpatory feedback delivered not only through one's hands during myofascial evaluation, but also when needling so as not to miss important information about underlying tissue health and/or disease that such changes in tissue resistance suggest.

GV 5

Xuan Shu "Suspended Pivot"

On the dorsal midline, in the depression caudal to the L1 spinous process.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae. In the lumbar spine, the connective tissue of the supraspinous ligament arises from the midline attachments of the dorsal layer of the thoracolumbar fascia as well as the longissimus and multifidus muscles. Dense connective tissue fibers from the thoracolumbar fascia form distinctive bands that cross the midline and then merge with fibers from the other side to form the supraspinous and interspinous ligaments.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. The interspinous ligaments may represent an extension of thoracolumbar fascia.
- **Thoracolumbar fascia:** An extensive fascial sheet that encloses the deep muscles of the back, with lateral attachments to the internal oblique and transversus abdominis muscles.

Clinical Relevance: The midline connective tissues can be viewed as an integrated complex, called the "interspinous-supraspinous-thoracolumbar (IST) ligamentous complex".[1] It has been likened to a connective tissue sleeve, or stocking, linking the thoracolumbar fascia to the anterior longitudinal ligament of the spine. This functional connectivity allows the various components to work in an organized manner.

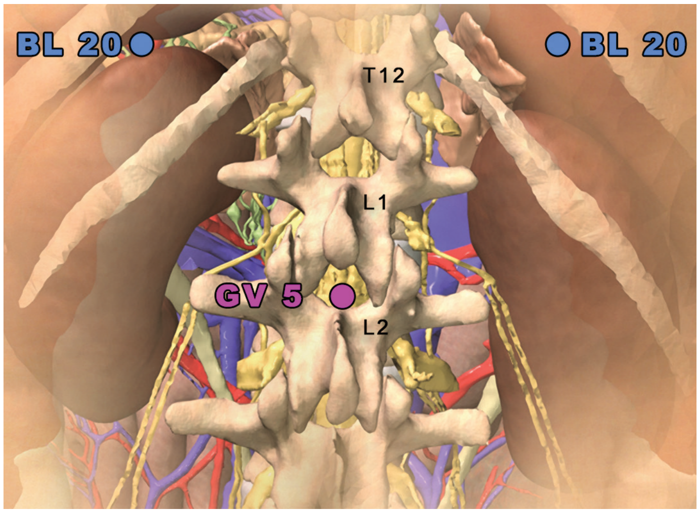

Figure 14-18. The name "Suspended Pivot" for GV 5 refers to the way in which L1 acts as a fulcrum for the thoracic and lumbar portions of the spine. A rich and varied collection of anatomical features occupies this truncal midsection. The iliohypogastric and ilioinguinal nerves angle in a caudolateral direction from L1, headed on a trajectory to supply the pelvis with sensory and sympathetic supply. Deep to GV 5, one sees the spinal cord through the intervertebral disk space. Renal vessels reach to and from the kidneys on either side of L1. The ureters, in light green, exit the renal pelvises and course toward the bladder. More ventral sit the intestines, large and small. The pinkish pyramidal adrenal glands rest atop the kidneys. Between the left kidney and spleen in the top left corner appears the pancreas and nearby lymph nodes, denoted by BL 20, the Back Shu point for the spleen or "spleen-pancreas". That is, because the ancient Chinese failed to recognize the physiologic significance and anatomic uniqueness of the pancreas they misattributed pancreatic activities to the spleen. The term "spleen-pancreas" is used to mitigate this oversight.

Furthermore, structural linkages between the thoracolumbar fascia, multifidus myofascia, supraspinous and interspinous ligaments, ligamentum flavum, and facet joint capsules, offer opportunities to reduce pain and debility from facet dysfunction by addressing thoracolumbar fascia tension and restriction.

Thoracolumbar fascia, in particular its dorsal (posterior) layer, facilitates load transfer between the spine, pelvis, and legs. Examine the connections it makes with major movers of the torso as shown in Figures 14-15, 14-16, and 14-19.

Dysfunction within the thoracolumbar fascia may introduce excessive pull on these attachments, causing cause intense and disabling pain. Interspinous locations such as GV points denote sites where strain patterns from the right and left sides intersect.

Nerves

- **Dorsal rami of lumbar spinal nerves from T11 to L1 or L2:** Innervate the local skin, muscles, and ligaments.

Clinical Relevance: Considering the spinal segmental nerve supply for GV 5 and the somatosomatic as well as somatovisceral reflex connections, neuromodulatory opportunities exist for treating thoracolumbar back pain, genitourinary conditions, kidney problems, and gastrointestinal disorders.

Sensory input from the kidney reaches the T10-T11 levels of the spinal cord, although the network of sympathetic preganglionic neurons actually spans a broader spinal segmental level, possibly extending into the cranial lumbar cord. Spinal cord segments ferrying sympathetic supply to the kidney become important targets for neuromodulation in patients with renal disease and hypertension. That is, neuromodulation of cranial lumbar spinal segments has the potential to reduce spinal cord sensitization and sympathetic over-activation.

GV points act on midline anatomy and neuromodulate by means of the medial branch of the dorsal primary ramus of the related spinal nerve. Points on the inner BL line have the capacity to influence both the medial and lateral branches of the dorsal primary rami, while outer BL line points impact predominantly the lateral branch. Even though points on the inner and outer BL channels initiate somatic afferent stimulation through different branches, the end clinical result often overlaps because sensory fibers from both locations travel through similar spinal nerves, destined to the same or adjacent spinal cord segments. One can select an interspinous GV line point at the same level to bolster spinal segmental attention.

Note that BL points on the back interact with muscle tissue whereas GV points largely do not. This translates into activating fewer types of nerve endings and mechanoreceptors with the latter, leading to less of a neuromodulatory impact compared to BL points. Treating only GV points for back pain would neglect the role of myofascial trigger point pathology its generation and perpetuation.

A "compromise" point location between GV points and the inner BL line is denoted by the Huatuojiaji point group. These sites occur

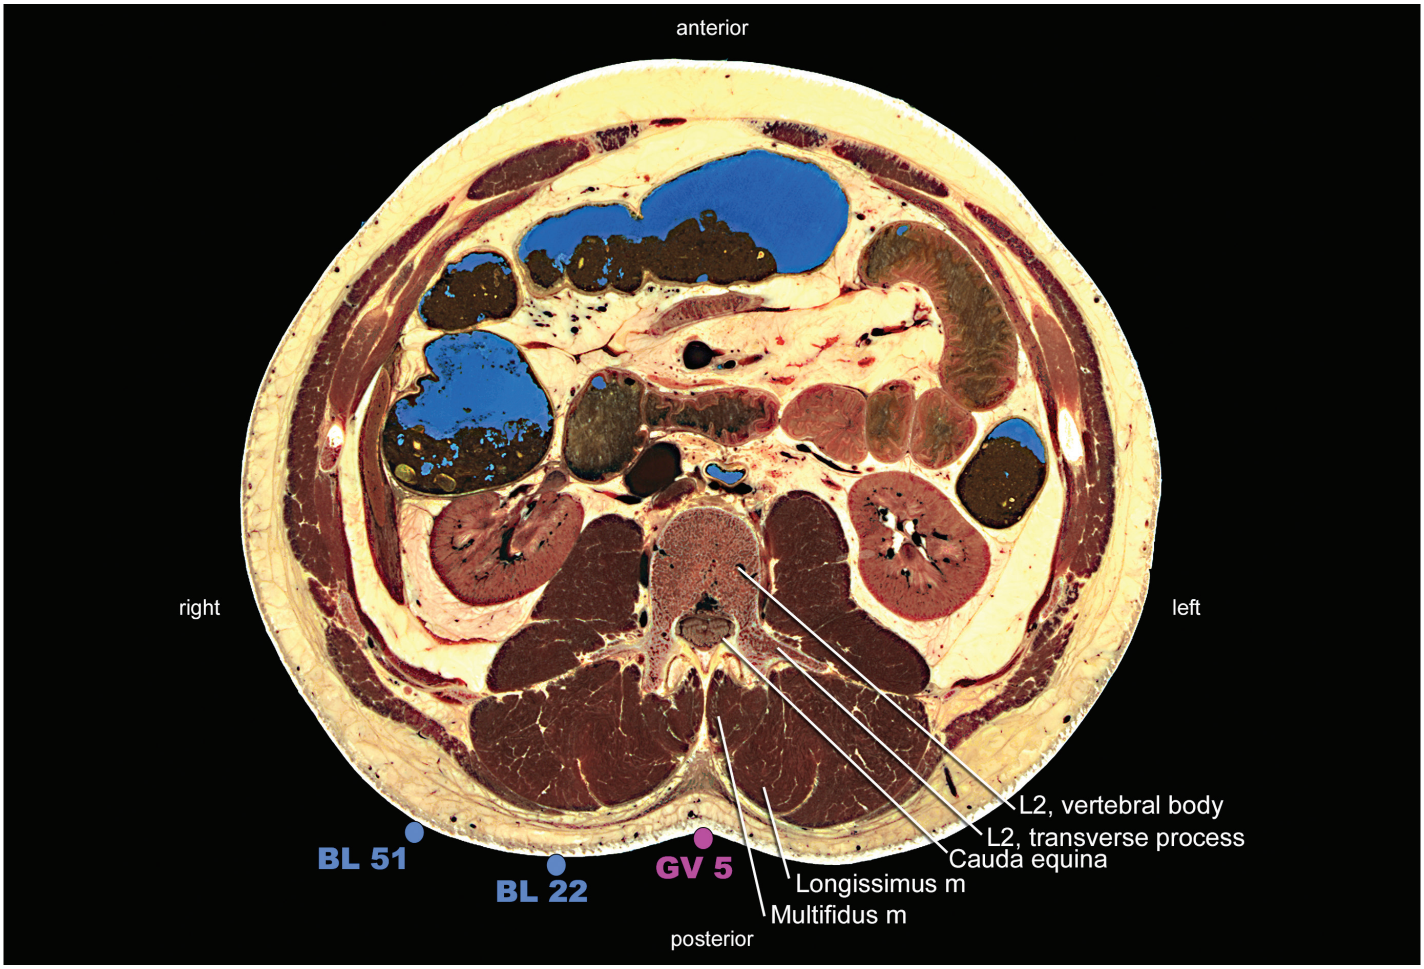

Figure 14-19. Note the anatomic "security blanket" of hypaxial and epaxial muscles that couches the L2 vertebral body at GV 5. When functioning well, these structures support spinal integrity and strength. When neurons misfire, myofascial pathology and proprioceptive confusion erupt, calling for neuromodulation with acupuncture and/or related techniques.

at each vertebral level, 0.5 cun from midline. They target both muscle tissue and potentially both medial and lateral branches of the dorsal primary ramus, depending on the spinal level.

Anatomically, as shown by Figure 14-19, Huatuojiaji points would influence the multifidus muscle, i.e., part of the spinalis group, rather than the longissimus or iliocostalis band. Treating back pain effectively requires astute palpation in order to define which muscles, fascial layers, and trigger points are causing problems. Acupuncture needling, manual therapy, and laser treatment can then target the actual source(s) of pain. That is, focusing on unaffected or less affected zones other than main problem may confer indirect benefit but leave the largest source of tension and myofascial pathology relatively untouched.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.

- **Dorsal branches of right and left 1st lumbar arteries:** The lumbar arteries branch off of the aorta and hug their respective vertebrae. Each lumbar artery supplies twigs to its vertebral body; dorsal branches from the artery also supply the back muscles and spinous process on that vertebra.

Spinal branches enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bone, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches also supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Gastrointestinal problems, including diarrhea, dysentery, enterocolitis, dyspepsia, abdominal pain:** GV 5, BL 22, BL 25, CV 10, BL 21, ST 36, SP 6.
- **Lumbar pain:** GV 5, BL 22, BL 23, BL 25, local tender points, BL 39, BL 40, BL 60, KI 3.

GV 6

Ji Zhong "Center of the Spine"

On the dorsal midline, in the depression caudal to the T11 spinous process.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae. In the lumbar spine, the connective tissue of the supraspinous ligament arises from the midline attachments of the dorsal layer of the thoracolumbar fascia as well as the longissimus and multifidus muscles. Dense connective tissue fibers from the thoracolumbar fascia form distinctive bands that cross the midline and then merge with fibers from the other side to form the supraspinous and interspinous ligaments.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. The interspinous ligaments may represent an extension of thoracolumbar fascia.
- **Thoracolumbar fascia:** An extensive fascial sheet that encloses the deep muscles of the back, with lateral attachments to the internal oblique and transversus abdominis muscles.

Clinical Relevance: The midline connective tissues can be viewed as an integrated complex, called the "interspinous-supraspinous-thoracolumbar (IST) ligamentous complex".[1] It has been likened to a connective tissue sleeve, or stocking, linking the thoracolumbar fascia to the anterior longitudinal ligament of the spine. This functional connectivity allows the various components to work in an organized manner.

Furthermore, structural linkages between the thoracolumbar fascia, multifidus myofascia, supraspinous and interspinous ligaments, ligamentum flavum, and facet joint capsules, offer opportunities to reduce pain and debility from facet dysfunction by addressing thoracolumbar fascia tension and restriction.

Thoracolumbar fascia, in particular its dorsal (posterior) layer, facilitates load transfer between the spine, pelvis, and legs. Examine the connections it makes with major movers of the torso as shown in Figures 14-15, 14-16, and 14-19. Figure 14-22 reveals the way in which the thick, dorsal component of the thoracolumbar fascia has narrowed as it meets the caudal tendon of the trapezius muscle.

Dysfunction within the thoracolumbar fascia may introduce excessive pull on these attachments, causing cause intense and disabling pain. Note, too, as illustrated by Figure 14-20, how the insertion of the trapezius tendon onto the caudal thoracic spinous processes increases traction on this "Center of the Spine".

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the source of much myofascial discomfort. Releasing its caudal connection to the thoracic spine at GV 6 and thereabouts may aid in the resolution of tension and strain patterns in the back, neck, and head.

Nerves

- **Dorsal rami of thoracic spinal nerves from T11 and nearby spinal segmental levels:** Innervate the local skin, muscles, and ligaments.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

Clinical Relevance: Considering the spinal segmental nerve supply for GV 6 and the somatosomatic as well as somatovisceral reflex connections therefrom, neuromodulatory opportunities exist for treating thoracolumbar back pain, splenic disorders, hepatobiliary dysfunction, kidney problems, and gastrointestinal disorders. For example, over a quarter of patients with symptomatic gallstone disease report back pain referred to the area denoted by GV 6.[3]

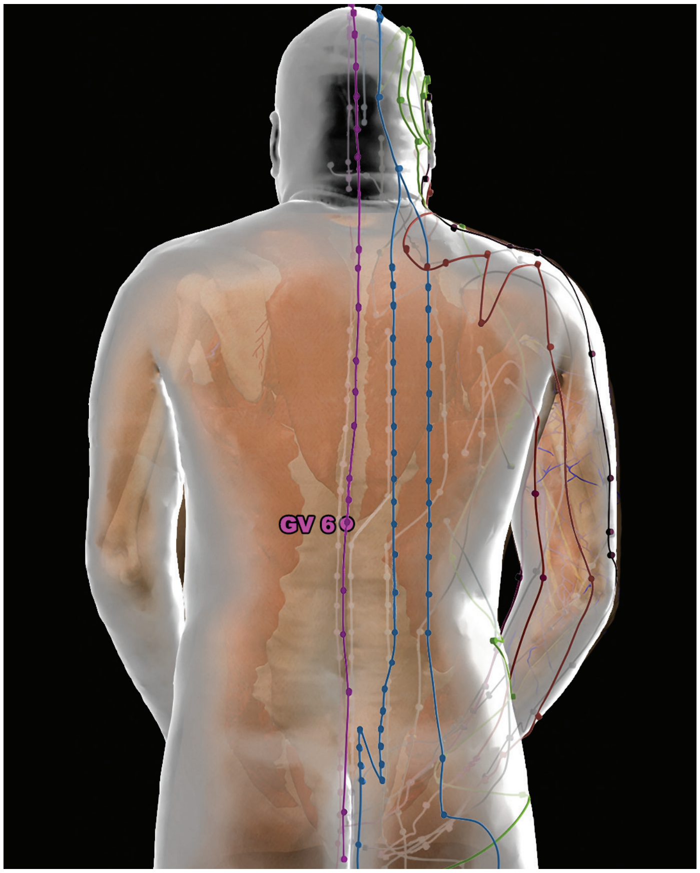

Figure 14-20. GV 6, called "Center of the Spine", is located at approximately the middle of the back.

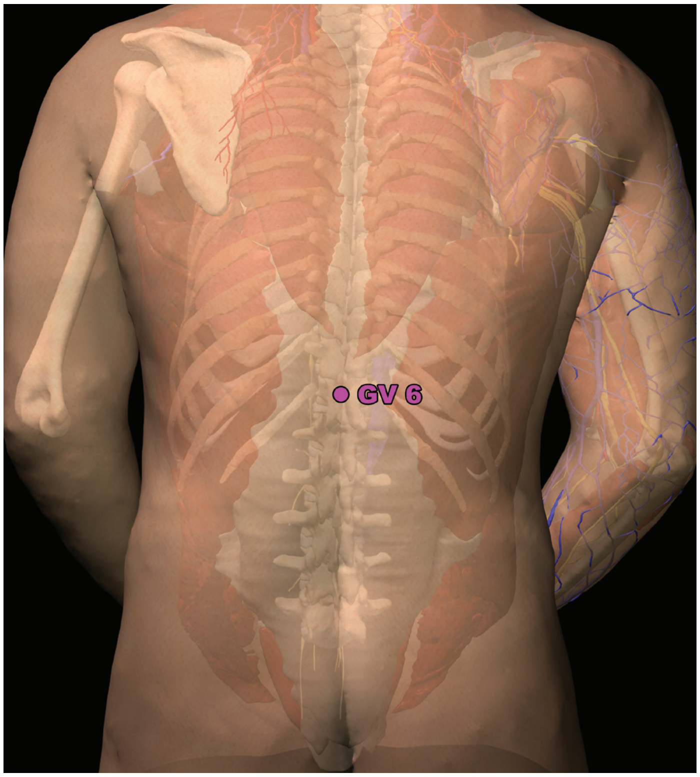

Figure 14-21. GV 6 lands at the interface where the thoracic spine becomes lumbar and the trapezius tendon turns to thoracolumbar fascia.

GV points act on midline anatomy and neuromodulate by means of the medial branch of the dorsal primary ramus of the related spinal nerve. Points on the inner BL line have the capacity to influence both the medial and lateral branches of the dorsal primary rami, while outer BL line points impact predominantly the lateral branch. Even though points on the inner and outer BL channels initiate somatic afferent stimulation through different branches, the end clinical result often overlaps because sensory fibers from both locations travel through similar spinal nerves, destined to the same or adjacent spinal cord segments. One can select an interspinous GV line point at the same level to bolster spinal segmental attention.

Note that, as evidenced by the cross-section in Figure 14-22, BL 20 (Back Shu point for the spleen) neighbors GV 6 at the T11-T12 level. Therefore, GV 6 could conceivably reinforce actions of BL 20 as well as the outer BL line point BL 49, located at this level as well. Furthermore, Figure 14-22 exposes the relationship of the spleen organ (and pancreas) to the left-sided BL 20 and BL 49.

Note that BL points on the back interact with muscle tissue whereas GV points largely do not. This translates into activating fewer types of nerve endings and mechanoreceptors with the latter, leading to less of a neuromodulatory impact compared to BL points. Treating only GV points for back pain would neglect the role of myofascial trigger point pathology its generation and perpetuation.

A "compromise" point location between GV points and the inner BL line is denoted by the Huatuojiaji point group. These sites occur at each vertebral level, 0.5 cun from midline. They target both muscle tissue and potentially both medial and lateral branches of the dorsal primary ramus, depending on the spinal level.

Treating back pain effectively requires astute palpation in order to define which muscles, fascial layers, and trigger points are causing problems. Acupuncture needling, manual therapy, and laser treatment can then target the actual source(s) of pain. That is, focusing on unaffected or less affected zones other than main problem may confer indirect benefit but leave the largest source of tension and myofascial pathology relatively untouched.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. However, drugs, air, and other material that enters or is injected into the epidural space can course through this valveless system and reach the heart or brain.

The epidural venous plexus communicates with the lumbar veins of the inferior vena caval system as well as the azygous system, the basivertebral vein, and the intracranial venous sinuses, including the sigmoid, occipital, and basilar venous sinuses. The epidural venous plexus extends its reach to the iliac veins through the sacral venous plexus.

The cerebrospinal venous system redistributes blood and equalizes pressure throughout the extensive valveless network.[2] The rich anastomosis between the vertebral venous system and the intracranial veins justifies the introduction of spinal level GV points for seizures and other intracranial conditions.

- **Dorsal branches of right and left 11th thoracic arteries:** The thoracic arteries arise from the posterior intercostal arteries, and embrace their respective vertebrae. Each thoracic artery supplies twigs to its related vertebral body; dorsal branches from each artery feed the back muscles and spinous process on that vertebra. Furthermore, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

GV 7

Zhong Shu “Central Pivot”

On the dorsal midline, in the depression caudal to the T10 spinous process.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae. In the lumbar spine, the connective tissue of the supraspinous ligament arises from the midline attachments of the dorsal layer of the thoracolumbar fascia as well as the longissimus and multifidus muscles. Dense connective tissue fibers from the thoracolumbar fascia form distinctive bands that cross the midline and then merge with fibers from the other side to form the supraspinous and interspinous ligaments.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. The interspinous ligaments may represent an extension of thoracolumbar fascia.
- **Thoracolumbar fascia:** An extensive fascial sheet that encloses the deep muscles of the back, with lateral attachments to the internal oblique and transversus abdominis muscles.

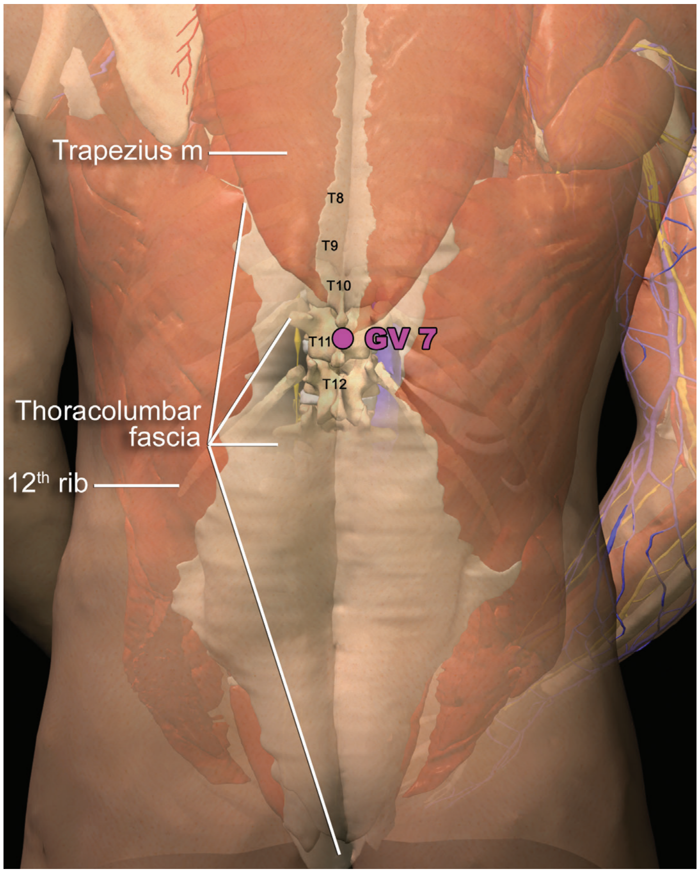

Figure 14-23. The descriptive names for GV 7, “Central Pivot”, “Spinal Center” (GV 6) and “Suspended Pivot” (GV 5) connote the anatomy and function of the spine. Lines defined by each border of the trapezius and the contralateral 12th rib intersect, or “pivot” around GV 7, hence its name. This image exposes the thoracolumbar fascia in its full extent, from T8 to the tip of the sacrum. A segment of the sympathetic chain of paraspinal ganglia appears just to the left of GV 7 and the inferior vena cava to its right.

Clinical Relevance: The midline connective tissues can be viewed as an integrated complex, called the “interspinous-supraspinous-thoracolumbar (IST) ligamentous complex”.[1] It has been likened to a connective tissue sleeve, or stocking, linking the thoracolumbar fascia to the anterior longitudinal ligament of the spine. This functional connectivity allows the various components to work in an organized manner.

Furthermore, structural linkages between the thoracolumbar fascia, multifidus myofascia, supraspinous and interspinous ligaments, ligamentum flavum, and facet joint capsules, offer opportunities to reduce pain and debility from facet dysfunction by addressing thoracolumbar fascia tension and restriction.

Thoracolumbar fascia, in particular its dorsal (posterior) layer, facilitates load transfer between the spine, pelvis, and legs. Examine the connections it makes with major movers of the torso as shown in Figures 14-15, 14-16, and 14-19.

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the source of much myofascial discomfort. Releasing its caudal connection to the thoracic spine at GV 7 and thereabouts may aid in the resolution of tension and strain patterns in the back, neck, and head.

Nerves

- **Dorsal rami of thoracic spinal nerves from T10 and nearby spinal segmental levels:** Innervate the local skin, muscles, and ligaments.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

Clinical Relevance: Considering the spinal segmental nerve supply for GV 7 and the somatosomatic as well as somatovisceral reflex connections therefrom, neuromodulatory opportunities exist for treating back pain, splenic disorders, hepatobiliary dysfunction, and upper gastrointestinal disorders. For example, over a quarter of patients with symptomatic gallstone disease report back pain referred to the vicinity of GV 7, level with BL 19 and BL 48 – see Figure 14-24.[2]

GV points act on midline anatomy and neuromodulate by means of the medial branch of the dorsal primary ramus of the related spinal nerve. Points on the inner BL line have the capacity to

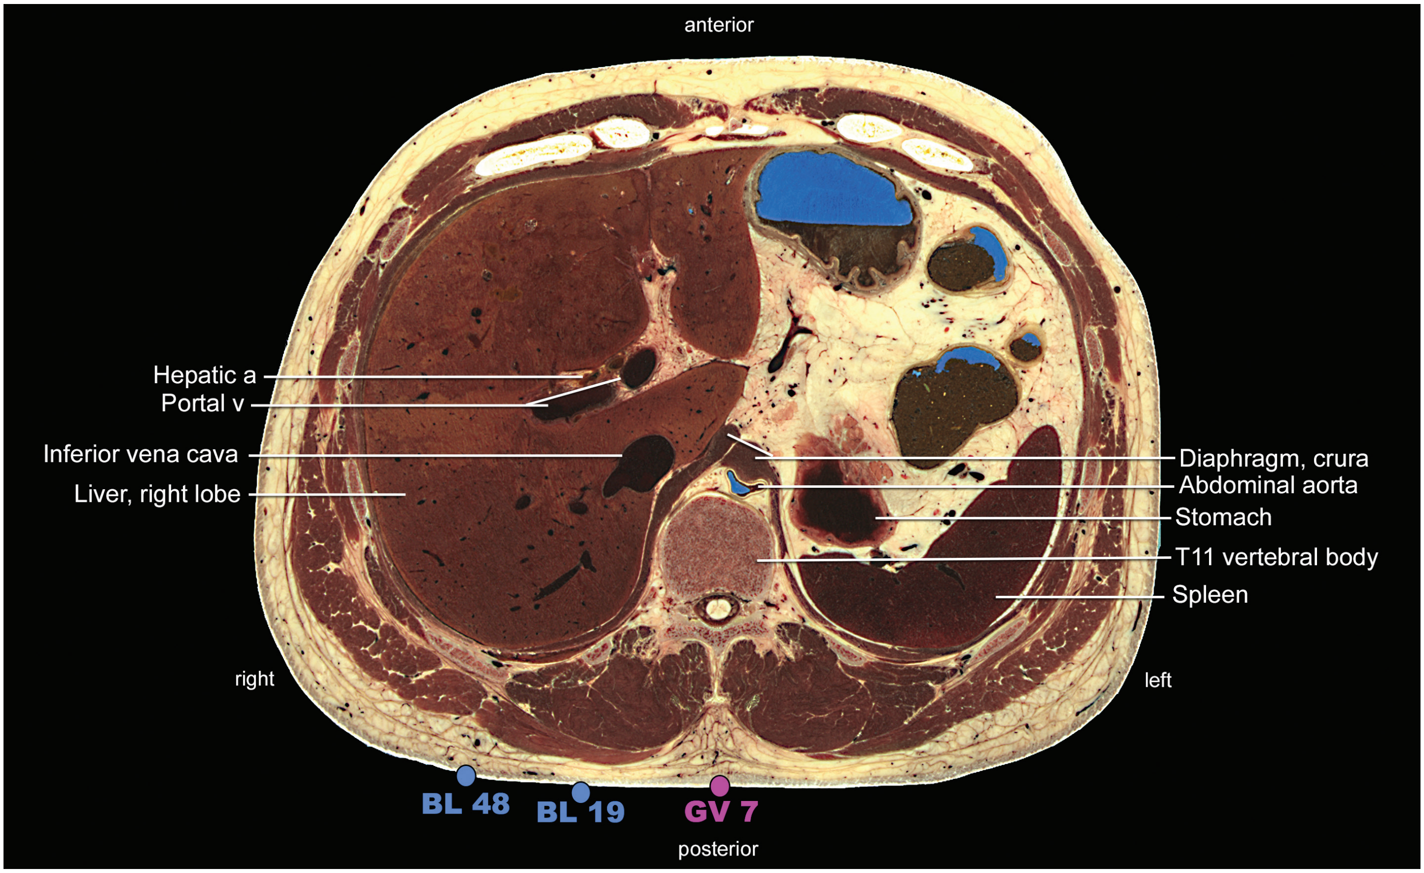

Figure 14-24. This cross-section, level with GV 7, BL 19, and BL 48, shows the liver and spleen, i.e., structures charged with cleansing and, when necessary, producing blood.

influence both the medial and lateral branches of the dorsal primary rami, while outer BL line points impact predominantly the lateral branch. Even though points on the inner and outer BL channels initiate somatic afferent stimulation through different branches, the end clinical result often overlaps because sensory fibers from both locations travel through similar spinal nerves, destined to the same or adjacent spinal cord segments. One can select an interspinous GV line point at the same level to bolster spinal segmental attention.

Note that BL points on the back interact with muscle tissue whereas GV points largely do not. This translates into activating fewer types of nerve endings and mechanoreceptors with the latter, leading to less of a neuromodulatory impact compared to BL points. Treating only GV points for back pain would neglect the role of myofascial trigger point pathology its generation and perpetuation.

A “compromise” point location between GV points and the inner BL line is denoted by the Huatuojiaji point group. These sites occur at each vertebral level, 0.5 cun from midline. They target both muscle tissue and potentially both medial and lateral branches of the dorsal primary ramus, depending on the spinal level.

Treating back pain effectively requires astute palpation in order to define which muscles, fascial layers, and trigger points are causing problems. Acupuncture needling, manual therapy, and laser treatment can then target the actual source(s) of pain. That is, focusing on unaffected or less affected zones other than main problem may confer indirect benefit but leave the largest source of tension and myofascial pathology relatively untouched.

Vessels

- Posterior external vertebral venous plexus: This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.
- **Dorsal branches of right and left 10th thoracic arteries:** The thoracic arteries arise from the posterior intercostal arteries, and embrace their respective vertebrae. Each thoracic artery supplies twigs to its related vertebral body; dorsal branches from each artery also supply the back muscles and spinous process on that vertebra. Furthermore, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Stiffness or pain in the thoracic spine on the midline:** GV 7, local tender points.
- **Icterus:** GV 7, BL 18, BL 19, ST 36, LR 3.
- **Cholelithiasis referring to the midback:** GV 7, BL 19, GB 24, ST 36, CV 12.
- **Nausea, vomiting:** GV 7, PC 6.

GV 8

Jin Suo "Sinew Contraction"

On the dorsal midline, in the depression caudal to the T9 spinous process.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae. In the lumbar spine, the connective tissue of the supraspinous ligament arises from the midline attachments of the dorsal layer of the thoracolumbar fascia as well as the longissimus and multifidus muscles. Dense connective tissue fibers from the thoracolumbar fascia form distinctive bands that cross the midline and then merge with fibers from the other side to form the supraspinous and interspinous ligaments.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. The interspinous ligaments may represent an extension of thoracolumbar fascia.
- **Thoracolumbar fascia:** An extensive fascial sheet that encloses the deep muscles of the back, with lateral attachments to the internal oblique and transversus abdominis muscles.

Clinical Relevance: The midline connective tissues can be viewed as an integrated complex, called the "interspinous-supraspinous-thoracolumbar (IST) ligamentous complex".[1] It has been likened to a connective tissue sleeve, or stocking, linking the thoracolumbar fascia to the anterior longitudinal ligament of the spine. This functional connectivity allows the various components to work in an organized manner.

Furthermore, structural linkages between the thoracolumbar fascia, multifidus myofascia, supraspinous and interspinous ligaments, ligamentum flavum, and facet joint capsules, offer opportunities to reduce pain and debility from facet dysfunction by addressing thoracolumbar fascia tension and restriction.

Thoracolumbar fascia, in particular its dorsal (posterior) layer, facilitates load transfer between the spine, pelvis, and legs. Examine the connections it makes with major movers of the torso as shown in Figures 14-15, 14-16, and 14-19.

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the source of much myofascial discomfort. Releasing its caudal connection to the thoracic spine at GV 8 and thereabouts may aid in the resolution of tension and strain patterns in the back, neck, and head.

Nerves

- **Dorsal rami of thoracic spinal nerves from T9 and nearby spinal segmental levels:** Innervate the local skin, muscles, and ligaments.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

Clinical Relevance: Considering the spinal segmental nerve supply for GV 8 and the somatosomatic as well as somatovisceral reflex connections therefrom, neuromodulatory opportunities exist for treating back pain, splenic disorders, hepatobiliary dysfunction, upper gastrointestinal disorders, and caudal lung lobe disease. To illustrate the viscerosomatic connection between the gallbladder and caudal mid-thoracic region, over a quarter of patients with symptomatic gallstone disease report back pain referred to the vicinity of GV 8, level with BL 18 and BL 47 – see Figure 14-26.[3]

GV points act on midline anatomy and neuromodulate by means of the medial branch of the dorsal primary ramus of the related spinal nerve. Points on the inner BL line have the capacity to influence both the medial and lateral branches of the dorsal primary rami, while outer BL line points impact predominantly the lateral branch. Even though points on the inner and outer BL channels initiate somatic afferent stimulation through different branches, the end clinical result often overlaps because sensory fibers from both locations travel through similar spinal nerves, destined to the same or adjacent spinal cord segments. One can select an interspinous GV line point at the same level to bolster spinal segmental attention.

Note that BL points on the back interact with muscle tissue whereas GV points largely do not. This translates into activating fewer types of nerve endings and mechanoreceptors with the latter, leading to less of a neuromodulatory impact compared to BL points. Treating only GV points for back pain would neglect the role of myofascial trigger point pathology its generation and perpetuation.

A "compromise" point location between GV points and the inner BL line is denoted by the Huatuojiaji point group. These sites occur at each vertebral level, 0.5 cun from midline, as depicted in Figures 14-25A and 14-26. Huatuojiaji points target both muscle tissue and potentially both medial and lateral branches of the dorsal primary ramus, depending on the spinal level. In Figure 14-26, note the distinct difference in muscle tissue "marbling" and fibrous tissue distribution between the transversospinalis group and the longissimus/iliocostalis muscles. Muscles that surround the trunk, including the latissimus dorsi and external abdominal oblique muscles, exhibit another characteristic appearance altogether.

Treating back pain effectively requires astute palpation in order to define which muscles, fascial layers, and trigger points are causing problems. Acupuncture needling, manual therapy, and laser treatment can then target the actual source(s) of pain. That

is, focusing on unaffected or less affected zones other than main problem may confer indirect benefit but leave the largest source of tension and myofascial pathology relatively untouched.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.

- **Juncture of the hemiazygous, accessory hemiazygous, and azygous veins from T6 to T9:**[2] (See Figure 14-25C.)

The left side of the caudodorsal body wall drains into the hemiazygous vein caudal to the connection with the azygous vein across the mid-thoracic vertebral bodies.

Cranial to the hemiazygous-azygous juncture at about T8, the accessory hemiazygous vein drains the posterior body wall. The hemiazygous vein begins as a continuation of the left ascending lumbar vein below the diaphragm. It ascends through the left intermediate crus of the diaphragm and travels up the caudal mediastinum to reach the vertebral body of T8 or T9. Somewhere between T6 and T9, the hemiazygous vein crosses the midline dorsal to the esophagus and descending thoracic aorta and ventral to the spine, headed to the azygous vein, into which it drains. The accessory hemiazygous vein also courses vertically along the dorsal mediastinum, left of T5-6 and T7-8. Its drainage pattern varies; at its cranial extent, it may form a continuous vessel with the left superior intercostal vein or drain into it. At its caudal end, it either joins with the hemiazygous vein or crosses obliquely ventral to the T7-T8 vertebrae to join the azygous vein directly.

- **Dorsal branches of right and left 9th thoracic arteries:** The thoracic arteries arise from the posterior intercostal arteries, and embrace their respective vertebrae. Each thoracic artery supplies twigs to its related vertebral body; dorsal branches from each artery also supply the back muscles and spinous process on that vertebra. Furthermore, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Spinal pain or stiffness:** GV 8, GV 4, BL 23, local tender points and areas of myofascial dysfunction.

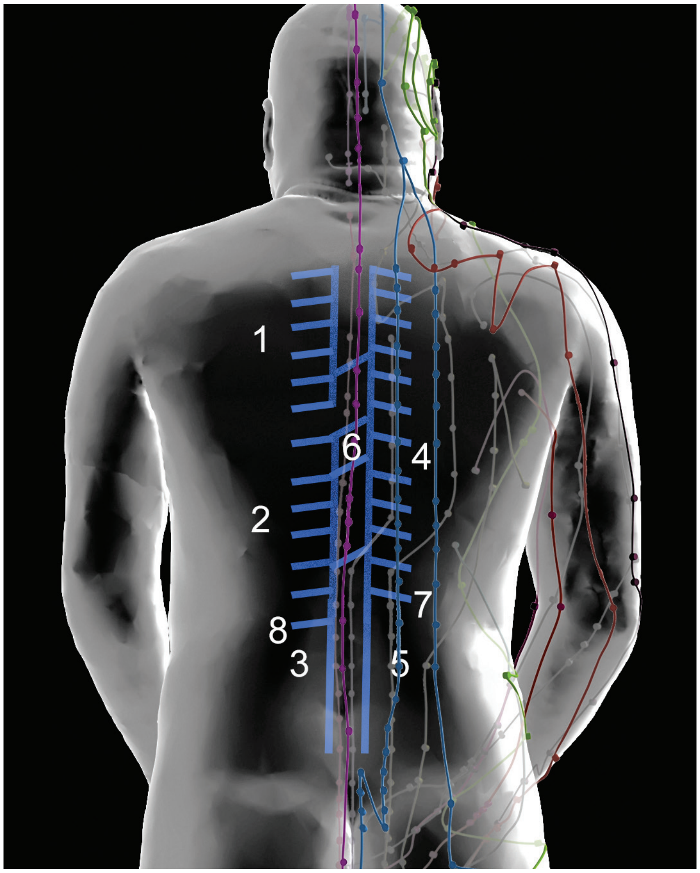

Figure 14-25C. Azygous system of veins. GV, as a singular vessel, embodies not only the vertebral venous plexuses but also the azygous venous network that drains deoxygenated blood from the dorsal body wall. The azygous system communicates directly with the vertebral venous plexuses as well as bronchial and pericardial veins, though anatomic variations occur often. In most cases, the azygous vein (4), exists only on the right side, formed from the union of the ascending lumbar (5) and right subcostal (7) veins. At its cranial extent (not shown), the azygous vein arches over the right main bronchus at the root of the lung to join the superior vena cava. The azygous system is asymmetrical, as this diagram indicates. That is, while deoxygenated blood from the right side of the back drains directly into the azygous, blood from the left caudal dorsal body wall drains into the hemiazygous (2), a vein that begins as the left ascending lumbar vein (3) or left renal vein (8). Venous blood from the left cranial back empties into the accessory hemiazygous (1) vein. The hemiazygous and accessory hemiazygous become tributaries of the azygous by means of any number of adjoining branches that cross the midline (6).

- **Impaired circulation to the spinal cord (compressive myelopathy, spinal cord infarction, etc.):** GV, Huatuojiaji, and facet joint points related to involved spinal segmental and vertebral levels. Laser, acupuncture, and soft tissue manual therapy to be applied gently.

posterior
T9 spinous process

Figure 14-26. Communication between the azygous and hemiazygous veins takes place between T6 and T9 on the ventral border of the vertebral bodies. The azygous vein appears in this cross section to the left of the aorta. The right intercostal vein shown here making its way toward the azygous is draining the posterior body wall. Deoxygenated blood from the caudal wall of the thorax will drain into the azygous system of veins and ultimately into the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and mediastinal, esophageal, and bronchial veins.

GV 9

Zhi Yang "Reaching Yang"

On the dorsal midline of the thorax, in the depression caudal to the spinous process T7. Approximately level with the caudal angle of the scapula.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae. In the lumbar spine, the connective tissue of the supraspinous ligament arises from the midline attachments of the dorsal layer of the thoracolumbar fascia as well as the longissimus and multifidus muscles. Dense connective tissue fibers from the thoracolumbar fascia form distinctive bands that cross the midline and then merge with fibers from the other side to form the supraspinous and interspinous ligaments.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. The interspinous ligaments may represent an extension of thoracolumbar fascia.
- **Thoracolumbar fascia:** An extensive fascial sheet that encloses the deep muscles of the back, with lateral attachments to the internal oblique and transversus abdominis muscles.

Clinical Relevance: Structural linkages between the thoracolumbar fascia, transversospinalis group myofascia, supraspinous and interspinous ligaments, ligamentum flavum, and facet joint capsules, offer opportunities to reduce pain and debility from facet dysfunction by addressing tension and restriction in the thoracolumbar fascia. This multilayered structure, i.e., the thoracolumbar fascia facilitates load transfer between the spine, pelvis, and legs. The fascia begins to dissipate at about the level of GV 9. Review its anatomy in Figures 14-25A and 14-25B.

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the source of much myofascial discomfort. Releasing its caudal connection to the thoracic spinous processes at GV 9 and thereabouts may aid in the resolution of tension and strain patterns in the back, neck, and head.

Nerves

- **Dorsal rami of thoracic spinal nerves from T7 and nearby spinal segmental levels:** Innervate the local skin, muscles, and ligaments.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

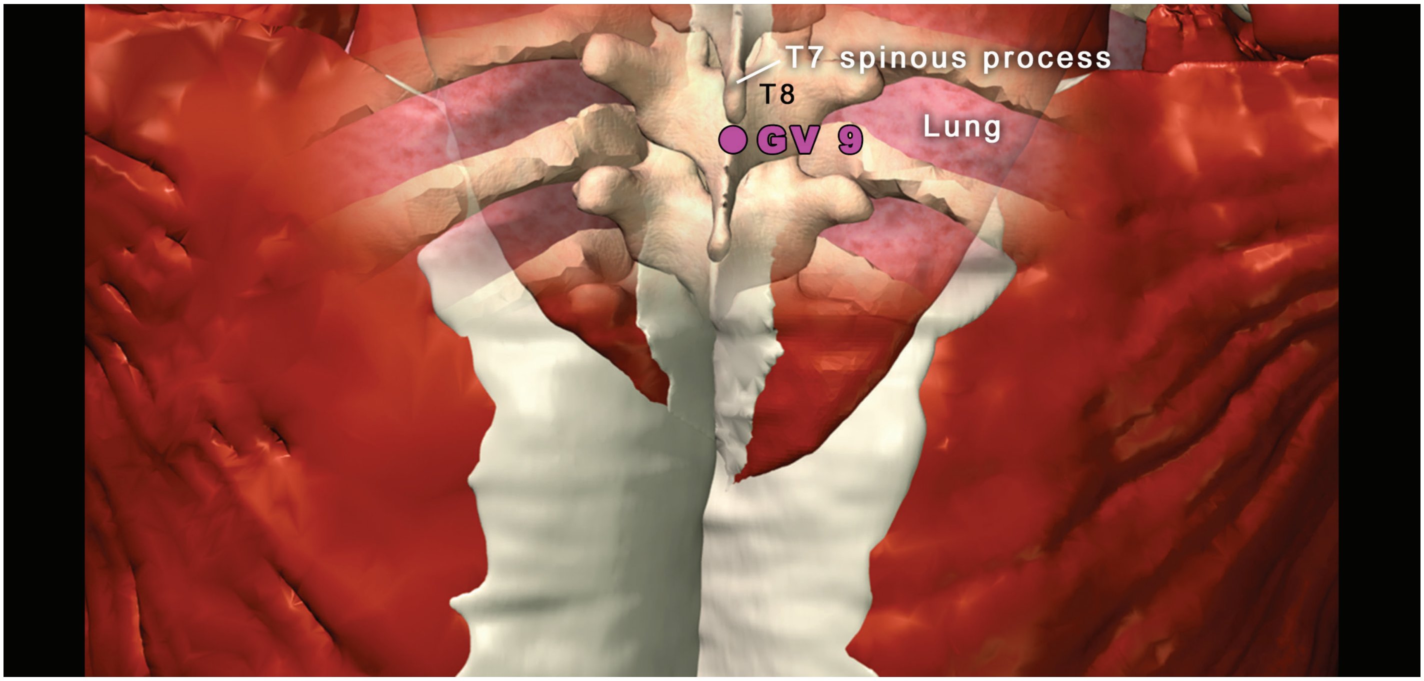

Figure 14-27. At "Reaching Yang" or GV 9, the GV channel reaches the thorax, filled by air-filled lungs (in the living individual). This contrasts with GV 8, located over the organ-dense abdomen (c.f. Figure 14-26). In Chinese medicine, chambers harboring air or empty space are considered "Yang" whereas solid or fluid-filled structures fall in the complementary "Yin" category. In this image, a window created through the dorsal musculature of the back allows visualization of the underlying lung tissue which, in the living individual, would expand with inspiration.

Figure 14-28. GV 9, GV 10, and GV 11 relate to diverse intrathoracic structures, including the heart, lungs, and esophagus. This horizontal plane also contains critical conduits such as the azygous venous network, pulmonary vein, thoracic duct, and aorta. Note, as well, the depth of myofascial tissue available for treatment through acupuncture and related techniques deep to GV 9. Not labeled but evident is the connection about to happen between the left posterior intercostal vein and the azygous system on the ventrolateral vertebral body of T7.

Clinical Relevance: Spinal segmental influences begat by neuromodulatory treatment at GV 9 may benefit problems associated with the back (via somatosomatic effects), vascular flow (through somatoautonomic effects) and/or internal organs by dint of somatovisceral reflexes. Both cardiopulmonary and cranial abdominal organs may refer pain to the mid-back. Note the numerous layers of connective tissue deep to GV 9 in Figure 14-28 as well as the multitude of vessels, including the thoracic duct, aorta, and azygous vein, shown ventral to the vertebral body of T7. This indicates that it may be possible to neuromodulate a variety of spinal cord activities governing a host of functions when activating the medial branch of the dorsal primary ramus at GV 9.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.
- **Juncture of the hemiazygous, accessory hemiazygous, and azygous veins from T6 to T9:**[1] (See Figure 14-25C.) The left side of the caudodorsal body wall drains into the hemiazygous vein caudal to the connection with the azygous vein across the mid-thoracic vertebral bodies. Cranial to the hemiazygous-azygous juncture at about T8, the accessory hemiazygous vein drains the posterior body wall. The hemiazygous vein begins as a continuation of the left ascending lumbar vein below the diaphragm. It ascends through the left intermediate crus of the diaphragm and travels up the caudal mediastinum to reach the vertebral body of T8 or T9. Somewhere between T6 and T9, the hemiazygous vein crosses the midline dorsal to the esophagus and descending thoracic aorta and ventral to the spine, headed to the azygous vein, into which it

drains. The accessory hemiazygous vein also courses vertically along the dorsal mediastinum, left of T5-6 and T7-8. Its drainage pattern varies; at its cranial extent, it may form a continuous vessel with the left superior intercostal vein or drain into it. At its caudal end, it either joins with the hemiazygous vein or crosses obliquely ventral to the T7-T8 vertebrae to join the azygous vein directly.

- **Dorsal branches of right and left 7th thoracic arteries:** The thoracic arteries arise from the posterior intercostal arteries, and embrace their respective vertebrae. Each thoracic artery supplies twigs to its related vertebral body; dorsal branches from each artery also supply the back muscles and spinous process on that vertebra. Furthermore, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Diaphragmatic irritation:** GV 9, BL 17, CV 16, KI 22.
- **Dysphagia:** GV 9, CV 22, CV 12, BL 10.
- **Pneumonia, cough, dyspnea:** GV 9, LU 1, LU 2, BL 13, BL 14, ST 36.
- **Cholecystitis, hepatitis:** GV 9, BL 18, BL 19, ST 36, GB 34.
- **Midthoracic pain:** GV 9 and areas of myofascial tenderness to palpation as indicated by palpation. Examine the region for sources of referred pain to this section of the back.

Evidence-Based Applications

- Acupuncture at GV 4, GV 9, GV 10, GV 11, GV 14, and GV 20 helped relieve symptoms related to **narcotic drug withdrawal.**[2]
- Moxibustion at GV 14, GV 9, and GV 4 produced **greater elevation of temperature** in the **lumbar region** than did administration of moxibustion at a single site, GV 14.[3] This makes sense, in that with the three-point application, GV 4 is in the lumbar region.
- Violet laser acupuncture applied to GV 14 raised **skin temperature** at GV 9, a "far field" point, indicating that thermal changes can occur at a distance from the stimulation site.[4]

GV 10

Ling Tai "Spirit Tower" "Spirit Terrace"

On the posterior midline of the thorax, in the depression inferior to the spinous process of the 6th thoracic vertebra (T6).

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices.

Clinical Relevance: Strain in the spinal ligaments exhibit strain patterns that may significantly alter joint mechanics.[3] Disruption of the posterior ligamentous complex (PLC) or other forms of ligamentous damage may compromise spinal stability.[4] PLC components display an orderly sequence of rupture when traumatized, beginning with distraction of the facet joint capsules and edema of the interspinous ligament. Following that, the supraspinous, interspinous, and flavum ligaments may rupture. Considering the impact of trauma on the sites that house GV points of the spine, palpation and treatment of local interspinous tender locations with acupuncture and related techniques for individuals with back pain or history of spinal trauma may ease discomfort and speed healing.

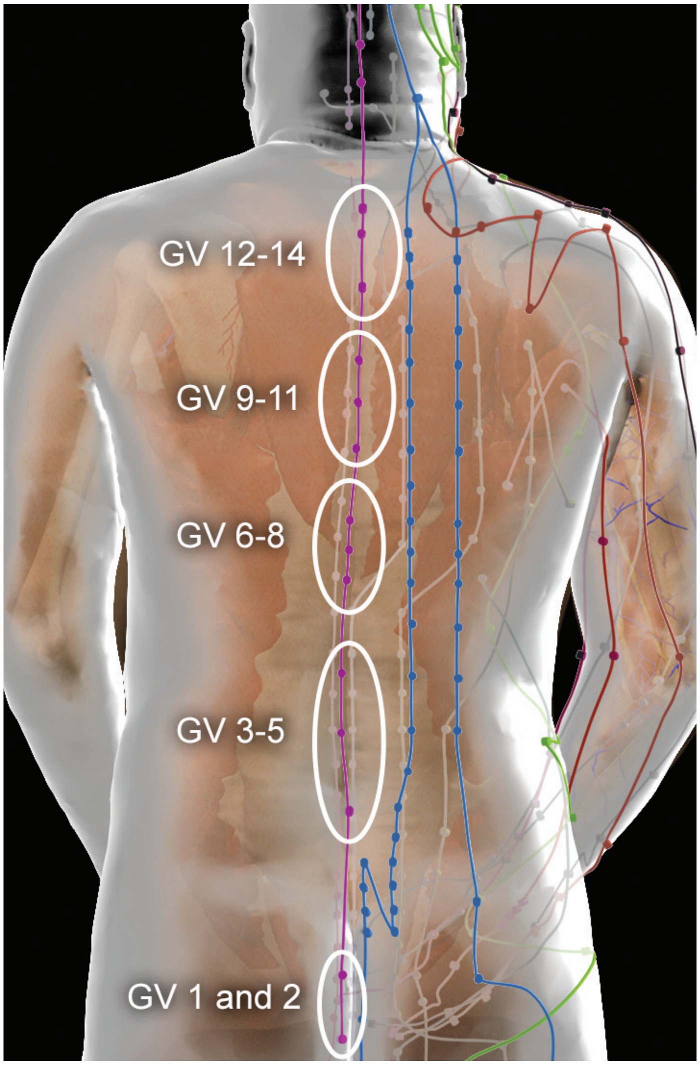

Figure 14-29. The name "Spirit Tower" or "Spirit Terrace" for GV 10 connotes an elevated locale from which a visionary or leader surveys her territory. With the spinal column as a platform and the heart where spirit resides (in ancient Chinese thought), GV 10 becomes a watchtower.

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the source of much myofascial discomfort. Releasing its attachment to the thoracic spinous processes near GV 10 and thereabouts may aid in the resolution of tension and strain patterns.

Nerves

- **Dorsal rami of thoracic spinal nerves from T6 and nearby spinal segmental levels:** Innervate the local skin, muscles, and ligaments.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

Clinical Relevance: Spinal segmental influences begat by neuromodulatory treatment at GV 10 may benefit problems associated with the back (via somatosomatic effects), vascular flow (through somatoautonomic effects) and/or internal organs by dint of somatovisceral reflexes. Dysfunction affecting the esophagus, heart, lungs, and cranial abdominal organs may refer pain to the mid-back. In fact, tenderness to palpation of GV 7, GV 8, GV 9, and GV 10 has been found to correspond with the presence of digestive disease.[5]

Note the numerous layers of connective tissue deep to GV 10 in Figure 14-30 as well as the multitude of vessels, including the thoracic duct, aorta, and azygous vein, housed ventral to the vertebral body. This indicates that it may be possible to neuromodulate a variety of spinal cord activities governing a host of functions when activating the medial branch of the dorsal primary ramus at GV 10.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain

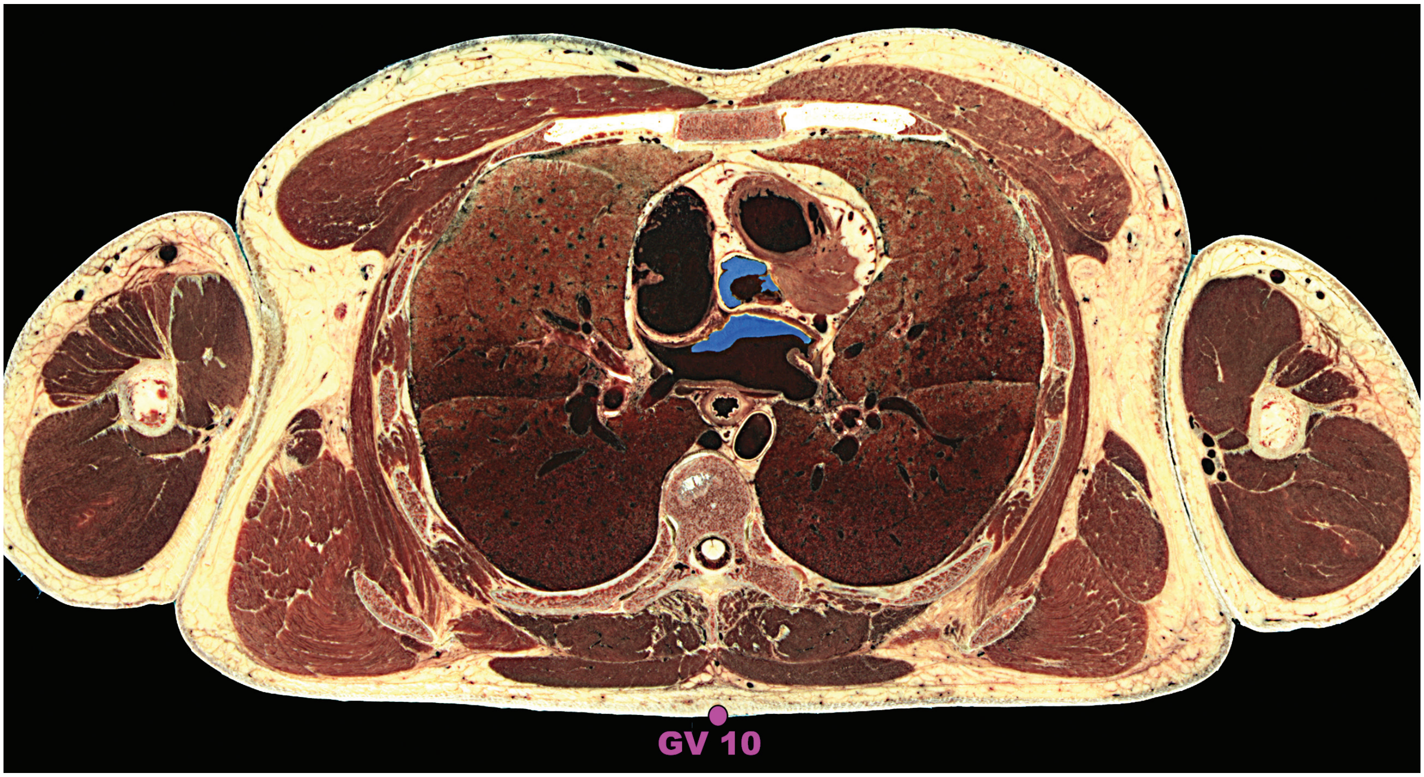

Figure 14-30. Ancient Taoists viewed the heart itself as a Sprit Tower (see Ellis et al in Grasping the Wind, p. 335). The relationship between GV 10 and the heart becomes clear with this cross section, as does the intimate association between the azygous vein, part of the GV, and the thoracic aorta (Chong Mai).

into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.

- **Juncture of the hemiazygous, accessory hemiazygous, and azygous veins from T6 to T9:**[1] (See Figure 14-25C.) The left side of the caudodorsal body wall drains into the hemiazygous vein caudal to the connection with the azygous vein across the mid-thoracic vertebral bodies. Cranial to the hemiazygous-azygous juncture at about T8, the accessory hemiazygous vein drains the posterior body wall. The hemiazygous vein begins as a continuation of the left ascending lumbar vein below the diaphragm. It ascends through the left intermediate crus of the diaphragm and travels up the caudal mediastinum to reach the vertebral body of T8 or T9. Somewhere between T6 and T9, the hemiazygous vein crosses the midline dorsal to the esophagus and descending thoracic aorta and ventral to the spine, headed to the azygous vein, into which it drains. The accessory hemiazygous vein also courses vertically along the dorsal mediastinum, left of T5-6 and T7-8. Its drainage pattern varies; at its cranial extent, it may form a continuous vessel with the left superior intercostal vein or drain into it. At its caudal end, it either joins with the hemiazygous vein or crosses obliquely ventral to the T7-T8 vertebrae to join the azygous vein directly.
- **Dorsal branches of right and left 6th thoracic arteries:** The thoracic arteries arise from the posterior intercostal arteries, and embrace their respective vertebrae. Each thoracic artery supplies twigs to its related vertebral body; dorsal branches from each artery also supply the back muscles and spinous process on that vertebra. Furthermore, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Respiratory issues (asthma, cough, dyspnea):** GV 10, GV 14, BL 15, BL 14, LU 7, LI 4, ST 36, and local tender points.

- **Thoracic back pain and stiffness:** GV 10, BL 16, BL 23, local tender trigger points and restricted myofascial dysfunction.
- **Neck stiffness:** GV 10, GV 14, BL 10, GB 20, as well as tender and tense myofascial dysfunction.
- **Digestive disorders of the cranial abdomen:** Palpate GV 7, GV 8, GV, 9, GV 10, and nearby BL points to examine for patterns related to one of more internal organs. Verify with further diagnostics as needed. Treat tender locations, Back Shu and Front Mu points for involved organs. Add PC 6 and/or ST 36.

Evidence-Based Applications

- Acupuncture at GV 4, GV 9, GV 10, GV 11, GV 14, and GV 20 helped relieve symptoms related to **narcotic drug withdrawal.**[2]
- Eliciting tenderness to palpation of GV 7, GV 8, GV 9, and GV 10 during the myofascial evaluation portion of the physical examination may cause one to consider the presence of **digestive disease**,[6] including gallbladder dysfunction.[7]

GV 11

Shen Dao "Spirit Pathway" "Spirit Path"

On the dorsal midline of the thorax, in the depression caudal to the T5 spinous process.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices.

Clinical Relevance: Spinal ligaments exhibit strain patterns that may significantly alter joint mechanics.[4] Disruption of the posterior ligamentous complex (PLC) or other forms of ligamentous damage may compromise spinal stability.[5] PLC components display an orderly sequence of rupture when traumatized, beginning with distraction of facet joint capsules and edema of the interspinous ligament. Following that, the supraspinous, interspinous, and flavum ligaments may tear. When one anticipates the impact of trauma on interspinous sites along the GV line, palpation and treatment of tender locations with acupuncture and related techniques may ease discomfort and speed healing in individuals with back pain or history of spinal trauma.

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the source of much myofascial discomfort. Releasing its attachment to the thoracic spinous processes near GV 11 and thereabouts may aid in the resolution of thoracic tension and strain patterns.

Nerves

- **Dorsal rami of thoracic spinal nerves from T3-T5:** Innervate the local skin, muscles, and ligaments.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

Clinical Relevance: Spinal segmental influences begat by neuromodulatory treatment at GV 11 may benefit problems associated with the back (via somatosomatic effects), vascular flow (through somatoautonomic effects) and/or internal organs by dint of somatovisceral reflexes. Dysfunction affecting the esophagus, heart, lungs, and cranial abdominal organs may refer pain to the mid-back. It may be possible to neuromodulate

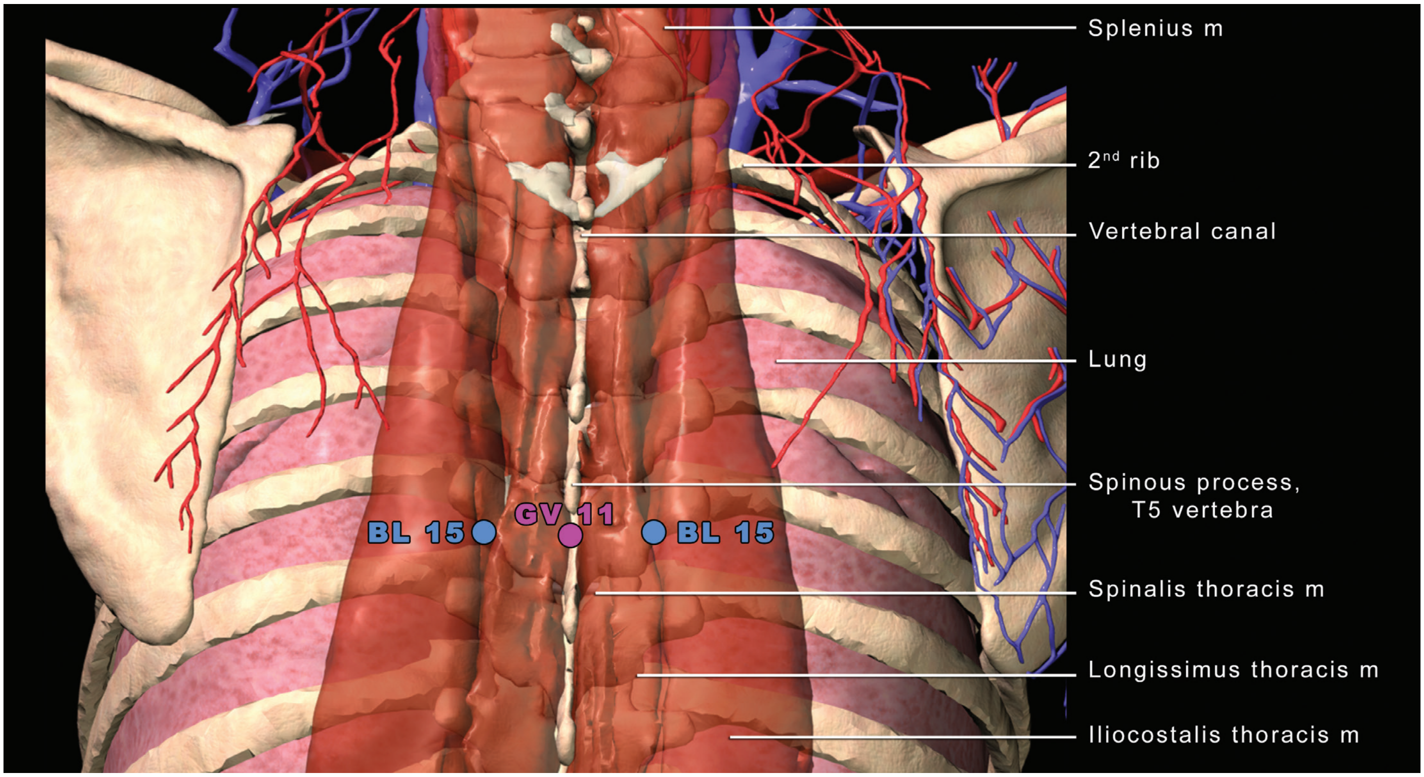

Figure 14-31. One finds GV 11, "Spirit Path", level with BL 15, the Back Shu points associated with the heart ("spirit residence"). Somatovisceral reflexes between the T5-T6 spinal segments and heart underlie these connections.

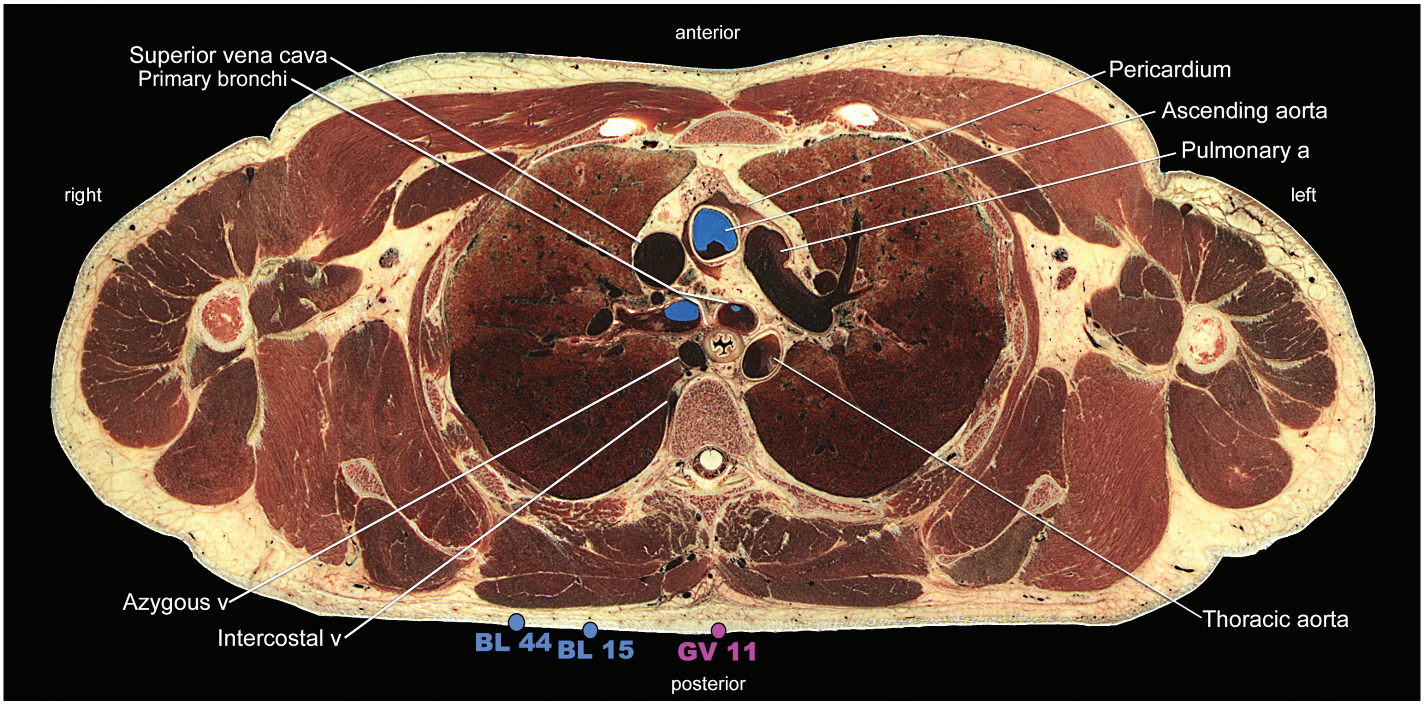

Figure 14-32. At its cranial extent, the azygous vein arches over the right main bronchus to join the superior vena cava. This cross-section cuts a plane just caudal to this connecting arch, exposing the two as separate structures on either side of the right primary bronchus. While somatovisceral reflexes provide a neuroanatomic pathway from GV 11 to the heart, deoxygenated blood reaches the heart by way of the azygous-superior vena caval connection. Either way, the name "Spirit Pathway" applies, given that "spirit" in Chinese medicine alludes to the heart as its home base.

a variety of spinal cord activities governing a host of functions when activating the medial branch of the dorsal primary ramus at GV 11.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.
- **Dorsal branches of right and left 5th thoracic arteries:** The thoracic arteries arise from the posterior intercostal arteries, and embrace their respective vertebrae. Each thoracic artery supplies twigs to its related vertebral body; dorsal branches from each artery also supply the back muscles and spinous process on that vertebra. Furthermore, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Tension in the back that radiates to the chest, intercostal neuralgia, back pain and stiffness:** GV 11, trigger points along the intercostal region, myofascial trigger points.
- **Fear, anxiety, sorrow, worry:** GV 11, BL 14, BL 15, GV 20, ST 36, SP 6, LU 7, CV 17.

Evidence-Based Applications

- Electroacupuncture at GV 11 and GV 16 suppressed both hyperemia and excessive glutamate release during and after transient ischemia in gerbils. Both hyperemia and excessive glutamate after ischemia may be important factors contributing to brain damage via reperfusion injury. This suggests that such suppression contributes to the neuroprotective effects of electroacupuncture in cases of **ischemic brain damage.**[1]

- Acupuncture at GV 4, GV 9, GV 10, GV 11, GV 14, and GV 20 helped relieve symptoms related to **narcotic drug withdrawal.**[2]
- A Chinese study reported that treating GV 11 with a retained needle resulted in reduced symptom scores and serum IgE levels in patients with **chronic urticaria.**[3]

GV 12

Shen Zhu "Body Pillar"

On the dorsal midline of the thorax, in the depression caudal to the T3 spinous process.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices.

Clinical Relevance: Spinal ligaments may exhibit strain patterns that may significantly alter joint mechanics.[2] Disruption of the posterior ligamentous complex (PLC) or other forms of ligamentous damage may compromise spinal stability.[3] PLC components display an orderly sequence of rupture when traumatized, beginning with distraction of facet joint capsules and edema of the interspinous ligament. Following that, the supraspinous, interspinous, and flavum ligaments may tear. When one anticipates the impact of trauma on interspinous sites along the GV line, palpation and treatment of tender locations with acupuncture and related techniques may ease discomfort and speed healing in individuals with back pain or history of spinal trauma.

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

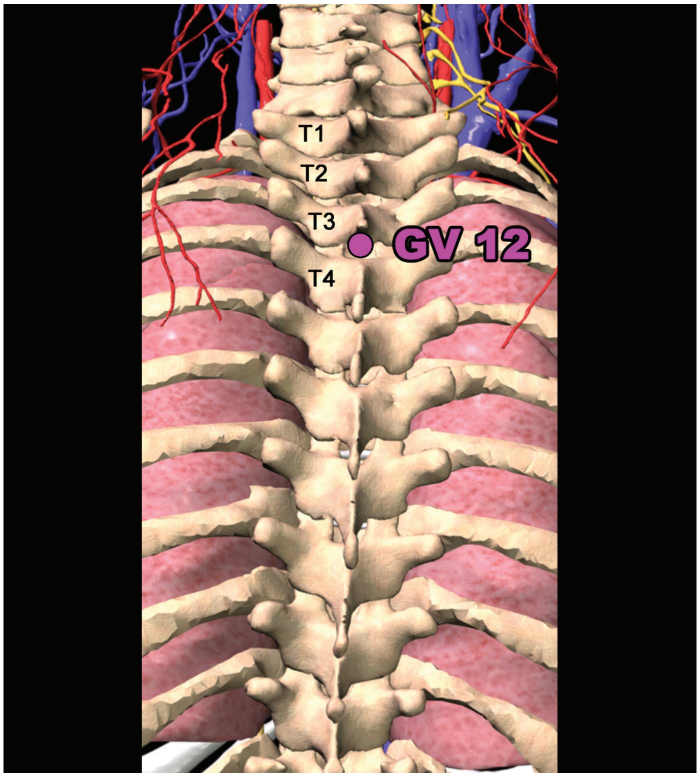

Figure 14-33. GV 12, called "Body Pillar" evokes the image of a weight-bearing column, i.e., the spine, with GV 12 sitting near the top.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the source of much myofascial discomfort. Releasing its attachment to the thoracic spinous processes near GV 12 and thereabouts may aid in the resolution of thoracic tension and strain patterns.

Nerves

- **Dorsal rami of thoracic spinal nerves from T2-T3:** Innervate the local skin, muscles, and ligaments.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

Clinical Relevance: Spinal segmental influences begat by neuromodulatory treatment at GV 12 may benefit problems associated with the back (via somatosomatic effects), vascular flow (through somatoautonomic effects) and/or internal organs by dint of somatovisceral reflexes. Dysfunction affecting the esophagus, heart, lungs, and cranial abdominal organs may refer pain to the mid-back. It may be possible to neuromodulate a variety of spinal cord activities governing a host of functions when activating the medial branch of the dorsal primary ramus at GV 12.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.

In the cranial thorax, the epidural venous plexuses anastomose with the superior intercostal veins by way of the intervertebral veins.[1] This links the vertebral venous system to the systemic venous network. It allows blood from the neck and thoracic limbs to course in a caudal direction through the epidural venous plexuses to the superior intercostal vein and into the azygous vein. Additional cervicothoracic level communications between

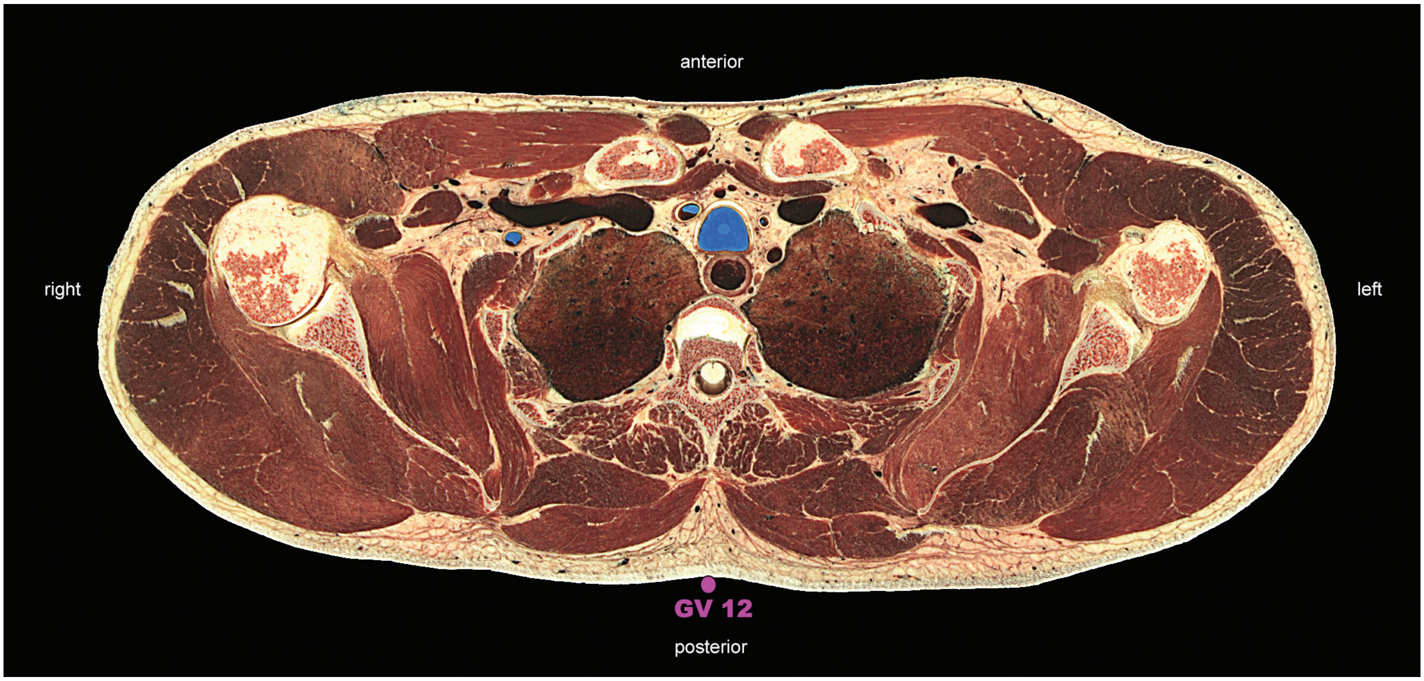

Figure 14-34. This cross-section at GV 12 portrays the abundant soft tissue deep to GV 12 and the nearby vicinity occupied by Huatuojiaji, facet, and BL line points. It also indicates the contrasting natures of the muscles filling the paraspinal grooves on each side. This view of the layered anatomy allows one to anticipate changes in tissue resistance to needle entry as the tip progresses through skin, subcutaneous fat, and, for the paraspinal points, the trapezius, and erector spinae muscles.

the vertebral venous system and the systemic venous network include connections between the longitudinal prevertebral vein, the superior intercostal vein, and the azygous venous system as well as juncture of the longitudinal prevertebral vein with veins of the upper esophagus.

- **Dorsal branches of right and left 3rd thoracic arteries:** The thoracic arteries arise from the posterior intercostal arteries, and embrace their respective vertebrae. Each thoracic artery supplies twigs to its related vertebral body; dorsal branches from each artery also supply the back muscles and spinous process on that vertebra. Furthermore, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Respiratory problems such as bronchitis, dyspnea, cough, asthma:** GV 12, BL 13, LI 4, LU 7,ST 36, CV 22, CV 17.
- **Thoracic back pain or stiffness:** GV 12, GB 21, local tender or tense trigger points.

GV 13

Tao Dao "Way of Happiness" "Happiness Path" "Kiln Path"

On the dorsal midline of the thorax, in the depression caudal to the spinous process T1.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices.

Clinical Relevance: Spinal ligaments may exhibit strain patterns that may significantly alter joint mechanics.[2] Disruption of the posterior ligamentous complex (PLC) or other forms of ligamentous damage may compromise spinal stability.[3] PLC components display an orderly sequence of rupture when traumatized, beginning with distraction of facet joint capsules and edema of the interspinous ligament. Following that, the supraspinous, interspinous, and flavum ligaments may tear. When one anticipates the impact of trauma on interspinous sites along the GV line, one can use palpation and treatment of tender locations with acupuncture and related techniques to ease discomfort and speed healing in individuals with back pain or history of spinal trauma.

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the source of much myofascial discomfort. Releasing its attachment to the thoracic spinous processes near GV 13 and thereabouts may aid in the resolution of thoracic tension and strain patterns.

Nerves

- **Dorsal rami of thoracic spinal nerves from C8-T1:** Innervate the local skin, muscles, and ligaments.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

Clinical Relevance: The location of GV 13 and GV 14 on the cranial thorax places them within a high traffic zone for the autonomic nervous system, susceptible to the neuromodulatory influences of acupuncture.

Spinal segmental influences induced by neuromodulatory techniques applied to GV 13 may benefit problems associated with the back (via somatosomatic effects), vascular flow (through somatoautonomic effects) and/or internal organs by dint of somatovisceral reflexes. Dysfunction affecting the esophagus, heart, lungs, and cranial abdominal organs may refer pain to the upper back or shoulder region. It may be possible to neuromodulate a variety of spinal cord activities governing a host of functions when activating the medial branch of the dorsal

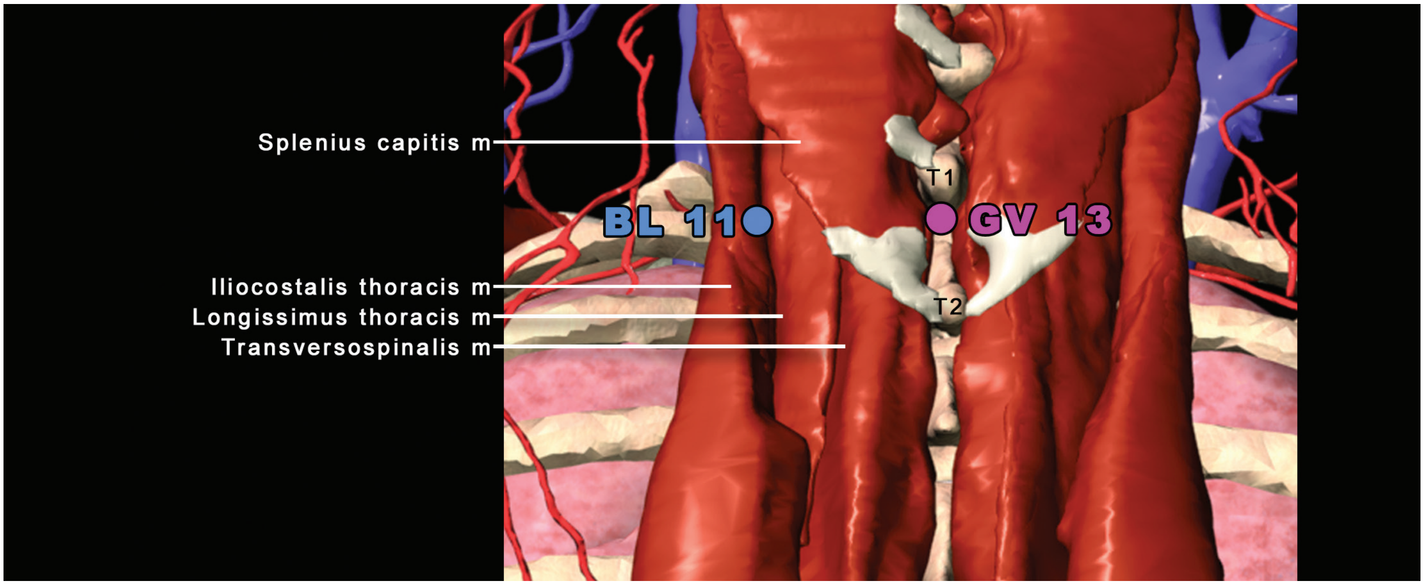

Figure 14-35A. The splenius capitis muscle resides deep to the trapezius muscle (not shown) and superficial to the erector spinae group (i.e., the transversospinalis, longissimus, and iliocostalis muscles). The splenius capitis arises from the caudal half of the nuchal ligament as well as the spinous processes of C7, T1, and T2, as indicated here. The muscle inserts onto the mastoid process of the temporal bone and just caudal to the superior nuchal line. Splenius capitis contraction thus causes the head to extend with bilateral contraction or side bend and rotate with unilateral activation. GV 13 sits between the right and left splenius capitis muscles at the myotendinous junction level, a zone rich with Golgi tendon organs.

primary ramus of the spinal nerves occurring at GV 13.

Respiratory conditions may benefit from GV 13 stimulation because somatovisceral reflexes travel from the point to spinal segments affecting the lungs and bronchi. Immune modulation ensues with reduction of sympathetic hyperactivity. Release of endogenous opioids, reduction in sympathetic tone, relaxation of regional musculature, and spinal cord neuromodulation work in concert to relieve neck and upper back pain.

Functionally, acupressure or acupuncture applied to GV 13, "Happiness Path", confers a relaxing, antinociceptive effect mediated at least in part by endogenous opioids. This harkens back to the response caused by scruffing the neck in certain non-human species.[4]

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.

In the cranial thorax, the epidural venous plexuses anastomose with the superior intercostal veins by way of the intervertebral veins.[1] This links the vertebral venous system to the systemic venous network. It allows blood from the neck and thoracic limbs to course in a caudal direction through the epidural venous plexuses to the superior intercostal vein and into the azygous vein. Additional cervicothoracic level communications between the vertebral venous system and the systemic venous network include connections between the longitudinal prevertebral vein, the superior intercostal vein, and the azygous venous system as well as juncture of the longitudinal prevertebral vein with veins of the upper esophagus.

- **Dorsal branches of right and left 1st thoracic arteries:** The thoracic arteries arise from the posterior intercostal arteries, and embrace their respective vertebrae. Each thoracic artery supplies twigs to its related vertebral body; dorsal branches from each artery also supply the back muscles and spinous process on that vertebra. Furthermore, spinal branches from each artery enter the vertebral (spinal) canal via the intervertebral foramen, providing blood supply to the bones, periosteum, and ligaments comprising the internal aspects of the vertebral canal walls. Some of these spinal branches supply the extradural or epidural space.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

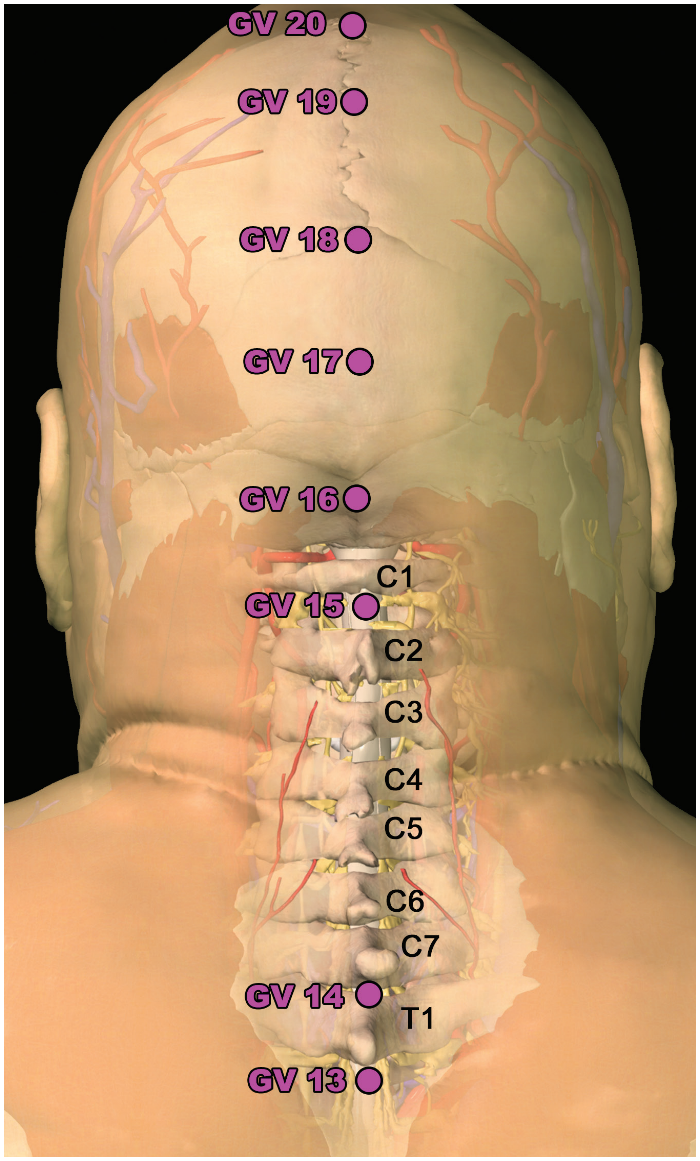

Figure 14-35B. Chinese kilns of old contained knobby projections resembling spinous processes. This explains the name "Kiln Path" for GV 13, located at the start of a bumpy road to the occiput.

Indications and Potential Point Combinations

- **Cervicothoracic pain or restriction:** GV 13, GV 14, BL 10, GB 21, local trigger points.
- **Torticollis:** GV 13, ST 10, ST 11, LI 16, LI 17, BL 10, GB 12, GB 20, local trigger points.

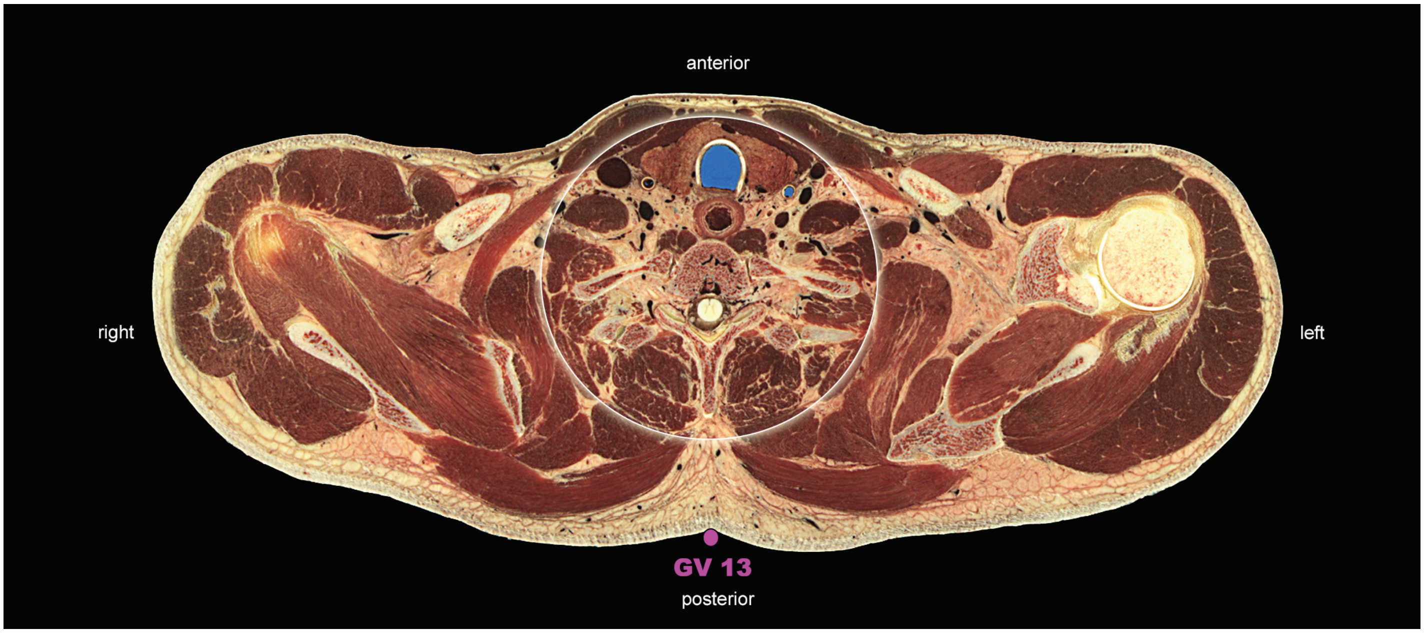

Figure 14-36. Anatomy of the body's core differs in structure and function from that around it. Note the change in tissue type and consistency when moving from inside to outside the circle. Within the circle appears the thyroid gland, major vessels, the trachea, esophagus, spinal cord, and muscles involved in stabilizing and bending the spine. Outside the circle, tissue function pertains more to movement than body maintenance, mainly composed of large appendicular musculature exhibiting substantial homogeneity. To see this cross-section with structures labeled, visit Figure 7-24, which examines this plane in relation to BL 11, level with GV 13.

- **Fever and chills:** GV 13, GV 14, LI 11, LI 4, ST 36, ST 44.
- **Cervicogenic cephalalgia:** GV 13, BL 10, BL 9, GV 20, LI 4, local trigger points.
- **Trapezius tension:** GV 13, GV 21, BL 10, GB 20, GV 20.
- **Dizziness:** GV 13, GV 20, GB 20, BL 10, LR 3, GB 34.
- **Feeling of heat throughout the body:** GV 13, GV 14, GV 20, ST 36, LR 3, LI 4.

GV 14

Daz Hui (or Da Zhui) "Great Hammer" or "Great Vertebra"

At the dorsal midline at the cervico-thoracic junction, in the depression caudal to the spinous process of C7.

In order to differentiate C7 from T1 for point localization, begin by identifying the two most prominent spinous processes in the cervicothoracic junction. Ask the patient to bend the neck forward while each of your thumbs contacts the two largest processes. The C7 spinous process will move cranial during cervical ventroflexion while the T1 spinous process will not, due to its relative fixation of position by the rib cage. GV 14 lands between the spinous processes of C7 and T1. See Figure 14-37B to appreciate the size of the C7 and T1 spinous processes compared to its more cranial counterparts.

Connective Tissues

- **Supraspinous ligament:** Connects the apices of the spinous processes of adjacent vertebrae.
- **Interspinous ligament:** Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. In the neck, the interspinous ligaments may be better described as fascial sheets.

Clinical Relevance: Spinal ligaments may exhibit strain patterns that may significantly alter joint mechanics.[20] Disruption of the posterior ligamentous complex (PLC) or other forms of ligamentous damage may compromise spinal stability.[21] PLC components, which include the supraspinous ligament, interspinous ligament, and ligamentum flavum, display an orderly sequence of rupture when traumatized, beginning with distraction of facet joint capsules and edema of the interspinous ligament. Following that, parts of the PLC may tear. When one anticipates the impact of trauma on interspinous sites along the GV line, one can use palpation and treatment of tender locations with acupuncture and related techniques to ease discomfort and speed healing in individuals with back pain or history of spinal trauma.

Tendons

- **Tendon of the trapezius muscle:** The trapezius originates from 1) the external occipital protuberance and superior nuchal line of the occipital bone, 2) the ligamentum nuchae, 3) the spinous process of the seventh cervical vertebra and the spinous processes of all thoracic vertebrae, and 4) the corresponding portions of the supraspinous ligament. The superior fibers insert onto the posterior aspect of the lateral clavicle; the middle fibers insert onto the acromion and the spine of the scapula; the inferior fibers converge near the scapula to end in an aponeurosis, which inserts onto a tubercle at the medial end of the spine of the scapula. The superior fibers elevate the scapula, the middle fibers retract it, and the inferior fibers depress the scapula.

Clinical Relevance: The trapezius muscle makes extensive connections throughout the upper body and constitutes the

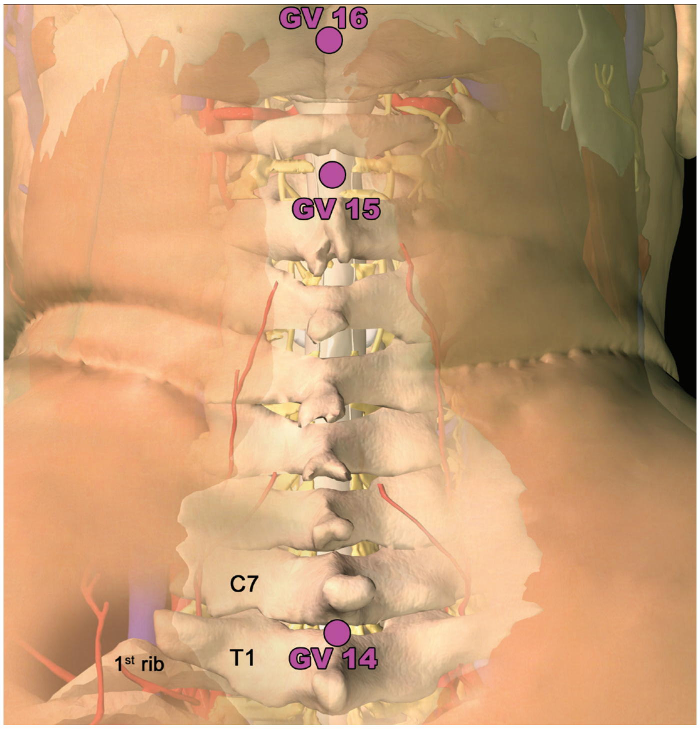

Figure 14-37A. GV 14, shown here between the spinous process of C7 and T1 can be challenging to locate. Because the first rib attaches to T1, this juncture restricts the spinous process from moving craniad when the patient ventroflexes the neck. Therefore, in order to distinguish between the C7 and T1 spinous processes, first identify the most prominent spinous processes in the cervicothoracic region. Palpate the processes while the patient flexes the neck. C7 will travel cranial with cervical flexion while T1 will not, or only minimally.

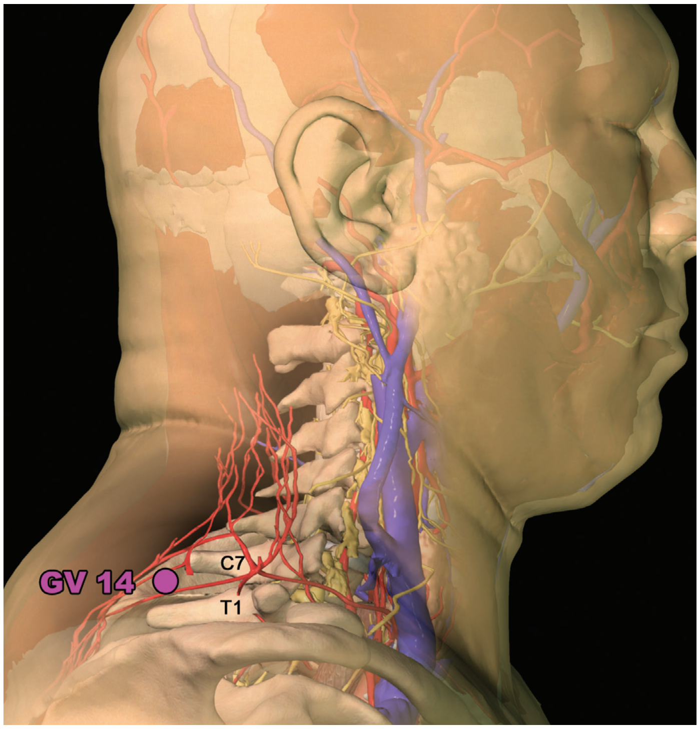

Figure 14-37B. The ancient Chinese metaphorically referred to the vertebrae as "spine hammers". C7, by having the largest spinous process of the cervical vertebrae, earns the name "Great Hammer" or "Great Vertebra".

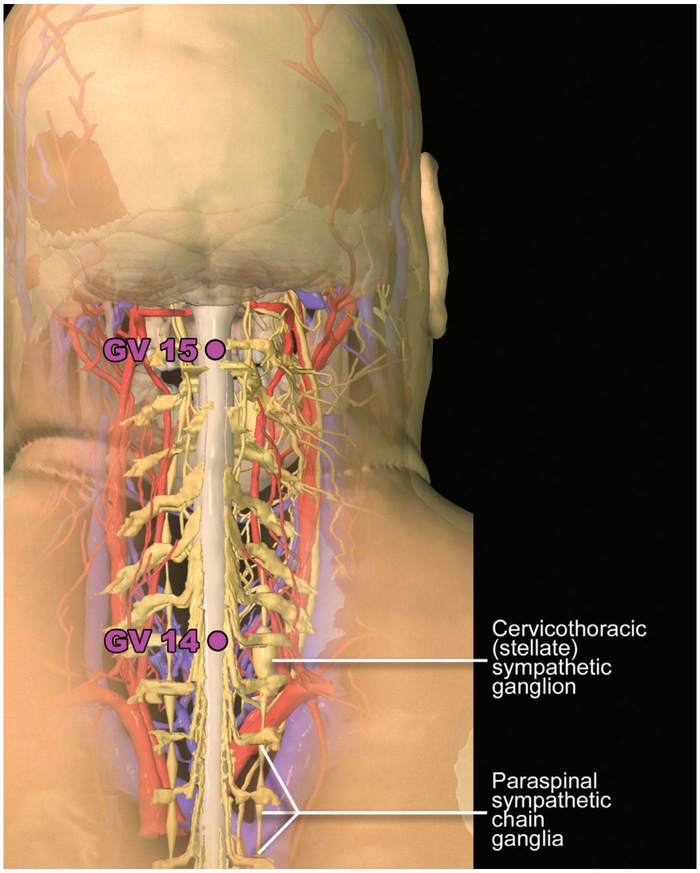

GV 15
GV 14
Cervicothoracic (stellate) sympathetic ganglion
Paraspinal sympathetic chain ganglia

Figure 14-38. GV 14 lands between the C8/T1 spinal cord segments and the C7/T1 vertebrae. This cervicothoracic region of the central nervous system marks the beginning of the sympathetic nervous system network within the spinal cord. In this depiction, the stellate ganglion can be seen to the right of GV 14 as a vertical oblong structure ventral to the horizontal spinal nerve.

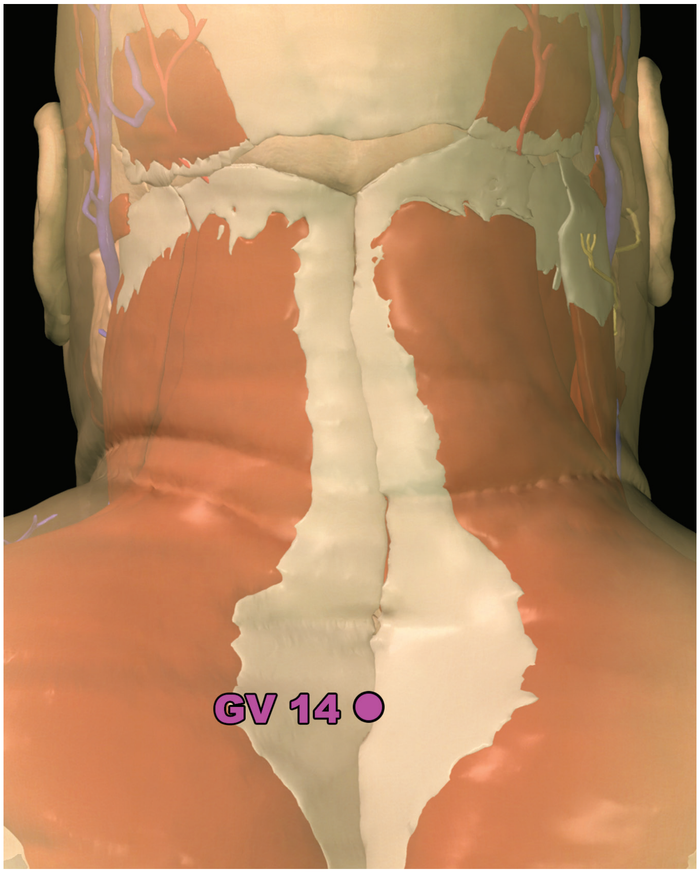

Figure 14-39. Beyond its immunoregulatory and neuromodulatory effects, GV 14 also treats neck and shoulder pain. The confluence of muscular attachments at this site justifies its inclusion in treatments to address myofascial restriction of the head and neck.

source of much myofascial discomfort. Releasing its attachment to the thoracic spinous processes near GV 14 and thereabouts may aid in the resolution of thoracic tension and strain patterns. View the trapezius fibers crossing the midline in Figure 14-40.

Beyond its local effects on the musculoskeletal system, stimulation of GV 14 exerts widespread influences on homeostasis. Somatic afferent convey impulses from GV 14 to the cranio-thoracic spinal cord segments and invoke autonomic nervous system modulation. This aids in normalizing circulation to myofascial tissue in the cervicothoracic region and reducing trigger point formation and perpetuation.

Nerves

- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.
- **Dorsal rami of thoracic spinal nerves from C6-T1:** Innervate the local skin, muscles, and ligaments.

Clinical Relevance: The location of GV 13 and GV 14 on the cranial thorax places them within a high traffic zone for the autonomic nervous system, susceptible to the neuromodulatory influences of acupuncture.

Preganglionic fibers emanating from the lateral horn of the upper thoracic spinal cord segments migrate to and synapse in the stellate (cervicothoracic, inferior), middle, or superior cervical sympathetic ganglia in the neck. These fibers supply head and neck structures as well as thoracic organs such as the heart. Embryologically, the heart developed in the neck; this helps explain why the fibers ascend from the cranial thoracic segments to the neck and back down to the thorax.

Spinal segmental influences induced by neuromodulatory techniques applied to GV 14 may benefit problems associated with the back (via somatosomatic effects), vascular flow and immune function (through somatoautonomic effects) and/or internal organs by dint of somatovisceral reflexes. Dysfunction affecting the esophagus, heart, lungs, and cranial abdominal organs may refer pain to the upper back or shoulder region. It may be possible to neuromodulate a variety of spinal cord activities governing a host of functions when activating the medial branch of the dorsal primary ramus of the spinal nerves occurring at GV 14.

Respiratory conditions may benefit from GV 14 stimulation because somatovisceral reflexes travel from the point to spinal segments affecting the lungs and bronchi. Immune modulation ensues with reduction of sympathetic hyperactivity. Release of endogenous opioids, reduction in sympathetic tone, relaxation of regional musculature, and spinal cord neuromodulation work in concert to relieve neck and upper back pain.

Functionally, acupressure or acupuncture applied to GV 14 confers a relaxing, antinociceptive effect mediated at least in part by endogenous opioids. This harkens back to the response caused by scruffing the neck in certain non-human species.[22]

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.

In the cranial thorax, the epidural venous plexuses anastomose with the superior intercostal veins by way of the intervertebral veins.[1] This links the vertebral venous system to the systemic venous network. It allows blood from the neck and thoracic limbs to course in a caudal direction through the epidural venous plexuses to the superior intercostal vein and into the azygous vein. Additional cervicothoracic level communications between the vertebral venous system and the systemic venous network include connections between the longitudinal prevertebral vein, the superior intercostal vein, and the azygous venous system as well as juncture of the longitudinal prevertebral vein with veins of the upper esophagus.

- **Right and left transverse cervical arteries:** From the thyrocervical trunk, the transverse cervical arteries supply the trunks of the brachial plexus via vasa nervorum. The transverse cervical arteries also supply muscles in the posterior cervical triangle, the trapezius, and the medial scapular region.

Clinical Relevance: Because the veins comprising the epidural venous plexus lack valves, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Arm and upper thoracic pain or weakness:** GV 14, neuroanatomically designated points according to the etiology of pain (e.g., trigger points for myofascial dysfunction) or weakness (e.g., neuropathic peripheral or spinal nerves, injured spinal cord segments).
- **Trapezius and cervical muscle tension:** GV 14, GB 21, GB 20, BL 10, BL 18, BL 23, local tender points or restricted regions.
- **Occipital headache:** GV 14, BL 10, BL 9, GV 20, GV 24.5, GV 21, local tender trigger points.
- **Seizures:** GV 14, ST 36, LR 3, HT 7, HT 3, BL 7, BL 8, BL 10, GV 20.
- **Immune regulation, early viral infection:** GV 14, LI 11, LI 4, ST 36, BL 13, BL 18, BL 23.
- **Hypertension:** GV 14, ST 36, LR 3, LI 4, HT 4, PC 6.
- **Respiratory problems, including bronchitis, asthma, and emphysema:** GV 14, BL 12, BL 13, LI 4, LU 7, ST 36.
- **Fever:** GV 14, GV 20, ST 36, LI 4, LR 3, BL 10.
- **Urticaria, eczema:** GV 14, LI 11, LI 4, ST 36, LU 7, LR 3, BL 18.

Evidence-Based Applications

- Acupuncture applied to GV 14, BL 13, LU 1, CV 17, ST 36, and SP 6 in rats with **immune-mediated pulmonary inflammatory lesions** countered the inflammatory process and deposition of collagen around ovalbumin-Sepharose beads which had been intravenously embolized to the lungs in rats pre-sensitized to that protein.[2]
- Case series studied application of GV 14 in cases of **acute upper respiratory infection, asthma, epilepsy, cervical arthritis, immune stimulation.**[3]
- Treatment for fever using GV 14, GB 20, and LI 11 in 57 patients with **common cold, influenza, acute tonsillitis, or acute bronchitis** helped normalize vital signs and increased T-lymphocytes.[4]
- Acupuncture stimulation at GV 14, BL 12, and BL 13 helps regulate **mucosal and cellular immunity for patients with allergic asthma.**[23]
- Acupuncture at GV 14, GV 15, and additional points improved hearing threshold by more than 20 dB in patients with **refractory sensorineural hearing loss** following failure of conventional therapy.[24]
- “Magnitopuncture” at PC 6 and GV 14 reduced the effects of **driving fatigue.**[5]
- A case report using acupuncture therapy for **intractable hiccups complicating acute myocardial infarction** showed that GV 14 rapidly terminated the hiccups.[6]
- Repeated acupuncture at ST 36, LI 11, SP 10, and GV 14 significantly decreased leukocyte and lymphocyte values in healthy humans, although cortisol and norepinephrine plasma levels remained unchanged. The mechanism whereby acupuncture affected **leukocyte circulation** was unclear (see following study).[7]
- Acupuncture at GV 14 may modify circulating levels of subpopulations of leukocytes by means of modulating **prostaglandin** levels. That is, the effect of acupuncture at GV 14 in **significantly**

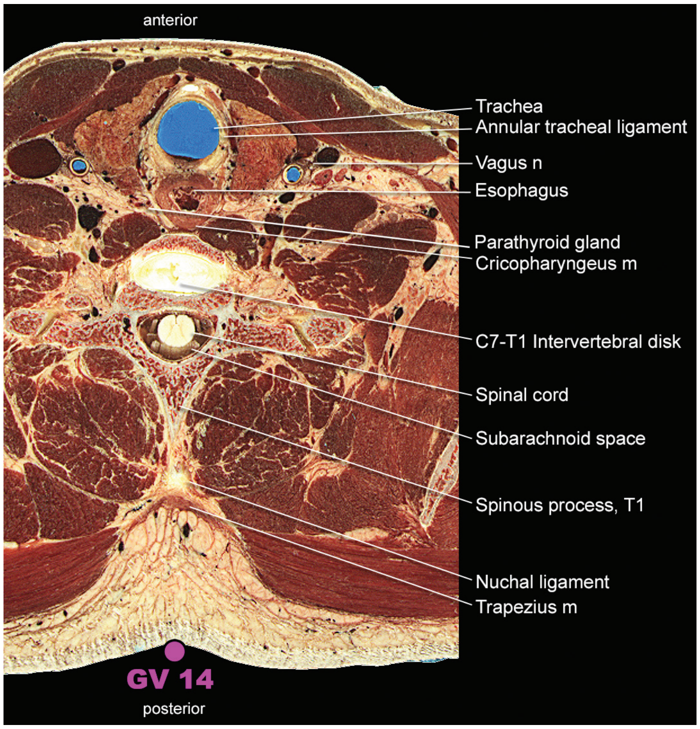

Figure 14-40. A needle entering GV 14 would first encounter the skin and subcutaneous tissue, followed by trapezius fibers, the supraspinous ligament, the nuchal ligament, and finally the T1 spinous process.

increasing leukocyte and neutrophil counts was **partially inhibited by the administration of aspirin prior to acupuncture.**[25]

- Violet laser acupuncture at GV 14 (405 nm, 110 mW, 500 micrometer spot size, time 10 minutes) produced significant increases in flux, i.e., the product of red blood cell concentration and flow velocity, 3 cm from the acupuncture point. This illustrated that violet laser acupuncture at GV 14 increases activity in the **local microcirculation.**

- Electroacupuncture at LI 4, LU 7, GV 14, GV 20, the thoracolumbar midline point San Tai and the lumbosacral midline point Baihui (veterinary) demonstrated a **reduction of minimum alveolar concentration (MAC) of isoflurane** by 16.7% in dogs. Acupuncture-assisted anesthesia thus potentiated the anesthetic effects of volatile anesthetic agents.[8]

- Acupuncture at GV 14 and GB 20 effectively treated **occipital neuralgia** in a series of cases.[9]

- Electroacupuncture at GV 2, GV 14, and ST 36 markedly **suppressed cortical epileptiform discharges** in rats. Possible mechanisms involved include alterations of opioid, serotonin, and gamma-aminobutyric acid (GABA) levels and recurrent inhibition of the cortex and hippocampus.[10]

- Electroacupuncture at GV 14, CV 20, CV 2, Yintang outperformed ST 36 and SP 6 in **alleviating cognitive deficits** in rats with experimentally induced epilepsy. The points on the head also abolished brain tissue shrinkage in the dorsal hippocampus, basolateral nucleus of the amygdala, substantia nigra, and reirhinal cortex, and stimulation of the two points on the limbs (ST 36 and SP 6) prevented brain shrinkage in the same areas except for the hippocampus. The effect was serotonin-dependent.[11]

- Electroacupuncture at GV 14, GV 20, GV 24.5, GV 16, GB 20, PC 6, and SP 6 produced more pronounced and long-lasting improvements in patients with **major depressive disorder** than did manual acupuncture. Acupuncture seems to accelerate the clinical response to the selective serotonin reuptake inhibitor class of anti-depressants.[26]

- A Chinese study reported success in addressing **vertebrobasilar ischemic vertigo** by means of filiform needling at ST 40, GB 20, GV 20, LU 7, and dermal needle tapping at GV 14 in order so regulate cerebral blood flow.[12]

- Violet laser acupuncture (405 nm, 110 mW, 500 micrometers spot size) applied to GV 14 **increased blood flow velocity in the basilar artery** (but not the middle cerebral artery to a significant extent) and also evoked at de qi sensation similar to manual acupuncture needle stimulation.[27]

- EA at GV 2, GV 14, GV 20, GV 24.5, **prevented tissue shrinkage of the dorsal hippocampus, basolateral nucleus of the amygdala, substantia nigra, and perirhinal cortex.** EA at ST 36 and SP 6 prevented tissue shrinkage in all of the aforementioned regions except for the dorsal hippocampus. EA to GV 2 + GV 14 + GV 20 + GV 24.5 or ST 36 + SP 6 reduced the cognitive deficits in pilocarpine-epileptic rats. Administration of p-chlorophenylalanine, a compound that depletes serotonin, negated the behavioral and some of the histologic changes due to EA. This suggests that the functional recovery exhibited by the rats may have been influenced through serotonergic pathways affected by acupuncture and subsequent **neuroprotective benefits.**[13]

- Acupuncture at GV 14, LU 7, GB 20, GB 5, and ST 8 effectively reduced the incident of **migraine without aura.**[14]

- Bleeding and cupping GV 14 provided analgesia for various painful conditions such as **toothache, headache, sore throat, and ocular inflammation.**[15]

- Acupuncture at GV 4, GV 9, GV 10, GV 11, GV 14, and GV 20 helped relieve symptoms related to **narcotic drug withdrawal.**[16]

- Acupuncture stimulation of GV 14 caused **hypothermia** via a decrease in metabolic rate, an increase in cutaneous circulation on the back, and perspiration. In contrast, acupuncture stimulation of PC 6 or ST 36 produced a slight hyperthermia, putatively due to a decrease in cutaneous circulation.[17]

- Violet laser acupuncture (405 nm, 110 nW, 500 micrometer spot size, 10 min stimulation) applied to GV 14 significantly **increased tissue temperature** at the point as well as in the "far field" area of GV 9.[28]

- Spinal cord stimulation at the C8-T1 segments suppressed excitatory responses to cardiac and esophageal inputs entering at T3-T4.[18] This may aid in explaining the benefits of GV 14 for **cardiac and esophageal problems.**

- Electroacupuncture stimulation of GV 14, GV 2, and LR 13 preserved vitality and decreased dorsal **skin flap necrosis** in experimental rats.[19]

GV 15

Ya Men "Gate of Muteness"

In the suboccipital region on the dorsal midline, in the depression cranial to the spinous process of C2. Located 1 cun caudal to GV 16.

Forbidden to electroacupuncture. Can cause stroke or seizure. No moxa. Avoid deep needle insertion.[1] Withdraw needle if uncomfortable or if it the patients claims that it feels like an electric shock.

Connective Tissues

- **Ligamentum nuchae (Nuchal ligament):** Comprises a dorsal midline raphe and a midline fascial septum. The dorsal midline raphe arises from the interweaving fibers on the right and left sides of the upper trapezius as well as the splenius capitis and rhomboid minor muscles. The raphe spans the cervical spine and attaches firmly to the external occipital protuberance and the C7 spinous process.

The midline fascial septum courses ventral to the dorsal midline raphe. It is confluent with the interspinous ligament, the atlanto-axial membrane, and the atlanto-occipital membrane.

- Interspinous ligament: Connects adjacent spinous processes by attaching spinous processes from their roots to their apices. In the neck, the interspinous ligaments constitute fascial sheets.

Clinical Relevance: The ligamentum nuchae may or may not attach to the cervical spinal dura mater between C1 and C2; this matter remains under investigation.[5] However, the rectus capitis posterior minor and major both do connect to the dura. Tension in these muscles causes neck pain and headache by placing traction on the dura. Because the caudal dura receives innervation from the vagus nerve, autonomic disturbances often accompany headache and migraine caused by dural traction.

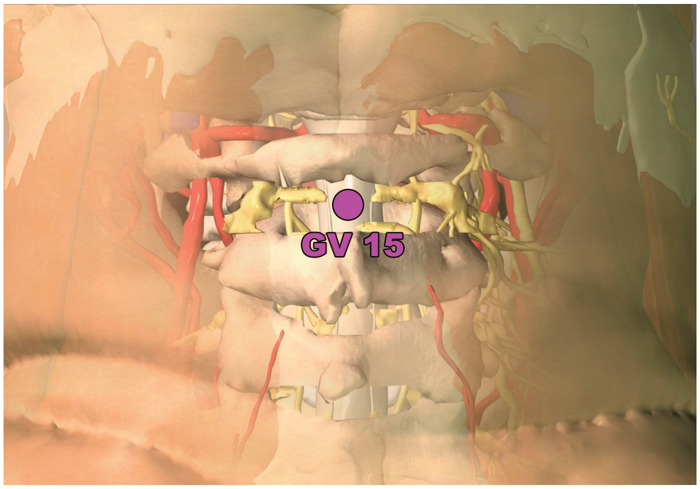

Figure 14-41. GV 15, "Mute's Gate", traditionally appears in formulae for language disorders. The point was considered a "gate" to the voice. However, deep needling at GV 15 may also render someone speechless by dint of death. Do not needle deeply at GV 15 or GV 16. Be aware, too, that even with manual therapy, sustained pressure applied to the suboccipital region can interfere with speech by affecting sensorimotor connections from cranial nerves between brain and buccal cavity by way of the cisterna magna.

Muscles

- **Trapezius muscle:** Fibers of the cranial, or superior, part of the trapezius elevate the scapula (i.e., when shrugging the shoulders).
- **Semispinalis capitis muscle, medial part:** Extends the head.
- **Rectus capitis posterior major muscle:** Provides proprioceptive input regarding head orientation and dural tension along with its partner, the rectus capitis posterior minor muscle. Also extends the head at the upper cervical spine.

Clinical Relevance: Myofascial dysfunction in many muscles on the back of the head and neck can lead to cervicogenic headache and instability.

Trigger points in the upper semispinalis capitis muscle adjacent to GV 15 incite radiating pain to the ipsilateral temporal region with diffuse pain that wraps around the head like a crown.

Trigger points in the suboccipital muscles tend to create pain perceived as penetrating the skull in a poorly localizable fashion. Patients may first complain that the entire head aches, but upon further questioning and examination, tenderness to palpation may center on a unilateral suboccipital focus.

In contrast to the way in which splenius cervicis trigger points causes pain that feels like it goes "right through the head", suboccipital trigger point pain is rarely so focused. Pain in the occipital regions can also arise from trigger points in the multifidi, levator scapulae, splenius cervicis, and infraspinatus muscles. Restriction in the soft tissues in the neck elevates pressure on large, vital neural, vascular, and glandular components, raising the potential for pain and suboptimal endocrine regulation.

The discovery of connections between suboccipital muscles (i.e., the rectus capitis posterior major and minor as well as the obliquus capitis inferior muscles[6]) and the dura explains a common etiology of cervicogenic headache.[7] Myodural connections form of soft tissue bridges in the atlantoaxial interspace level with GV 15 and the atlantooccipital interspace level with GV 16.

The soft tissue adjoining muscle to dura harbors proprioceptive neurons, implicating suboccipital muscles in aiding the brain in its control over head position and dural tension.[8] Researchers speculate that myodural biofeedback "may play a role in maintaining the integrity of the subarachnoid space and, subsequently, cerebrospinal pressure. If this mechanism does exist, its failure may result in a variety of clinical manifestations including those arising from increasing dural tension, namely cervicogenic headaches."[9]

While some have excised the myofascial bridge to alleviate chronic headache,[10] nonsurgical approaches should be tried first, including manual therapy, laser therapy, and cautious acupuncture.

Cervicogenic dizziness may result from abnormal afferent activity in cervical muscles.[11] Specifically, abnormal input that reaches vestibular nuclei from dysfunctional proprioceptors of the upper cervical region can contribute not only to neck pain and tension but also produce muscle spasms that aggravate dizziness. Dizziness worsens muscle spasm and muscle tension worsens dizziness. Patients may provide a history of looking upward with neck extended for a period of time preceding the dizziness. This should raise one's index of suspicion. However, rule out other possible diagnoses of dizziness or vertigo as well before assuming the cause is the neck.

If one suspects a cervicogenic cause of dysequilibrium, manual therapy, laser, and cautious acupuncture at GV 15, BL 10, and other regional points may be warranted.

Figure 14-43 examines the relationship between GV 15, the rectus capitis posterior major muscle, and the obliquus capitis inferior muscle. Note, too, the presence of deep cervical veins in this cross section, suggesting that manual therapy and/or laser therapy would provide safer means of addressing trigger point pathology in the deep suboccipital structures than would needling to reach these sites.

Nerves

- **Third ("Least") occipital nerve (C3):** Innervates the skin of the medial occipital and cervical regions. This dorsal ramus of the C3 spinal nerve separates into a complex system of branches after emerging from the articular pillar of the C3 vertebra. It divides into medial and lateral branches, with the medial further separating into deep and superficial divisions.[12]
- **Spinal nerves C2-C3, dorsal rami:** Innervate the posterior cranial fossa.
- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **Spinal nerves C2 – C4, dorsal rami:** Innervate semispinalis capitis muscle.

Clinical Relevance: Nerves in the suboccipital region may become entrapped in the layers of myofascia deep to GV-15, shown by Figure 14-43. Nerve entrapment causes pain and myofascial restriction.

Cervical zygapophyseal joints cause chronic neck pain and headache in up to half of patients. Facet joints receive innervation from the medial branches of the spinal nerves C3 to C7; each nerve supplies the joint above and below.

Although percutaneous radiofrequency ablation (RFA) has become an accepted nonsurgical modality for chronic neck pain, adverse outcomes may occur. RFA of the least (3rd) occipital nerve and the C2-C4 facet joints has led to "dropped head syndrome" in which the patient became unable of extending her neck, inducing a debilitating complication.[13] While acupuncture and related techniques may not be able to repair nerves completely destroyed by RFA, the risk of permanent disability emphasizes the need to address pain and functional compromise with safe and effective approaches such as acupuncture and related techniques before pursuing modalities that can cause irreversible damage.

Third occipital nerve (TON): This dorsal branch of the 3rd cervical spinal nerve must make its way through several layers of deep nuchal musculature, raising the potential for nerve entrapment and irritation. Thus, this nerve likely produces occipital neuralgia more than has been previously recognized.[14] Neuralgia originating from TON disorders mimics GON neuralgia. The superficial medial branch of the C3 spinal nerve, also called the 3rd or least occipital nerve, travels around the dorsolateral surface of the C2-3 zygopophysial (facet) joint that it supplies. It branches at about BL 10. While facet joints caudal to C2-3 receive innervation by the dorsal rami above and below the joint, the C2-3 facets only receive TON innervation. After supplying the facet joint, the TON continues on to supply the semispinalis capitis muscle, traveling deeply along this muscle until it sends a communicating branch to the greater occipital nerve. The risk of third occipital neuralgia increases as a result of its vulnerability to entrapment at the level of the intervertebral disk behind the intervertebral joints. Osteophytes in these joints can produce nerve compression and chronic headache that may remain undiagnosed as a result of clinicians' unfamiliarity with this nerve entrapment syndrome.

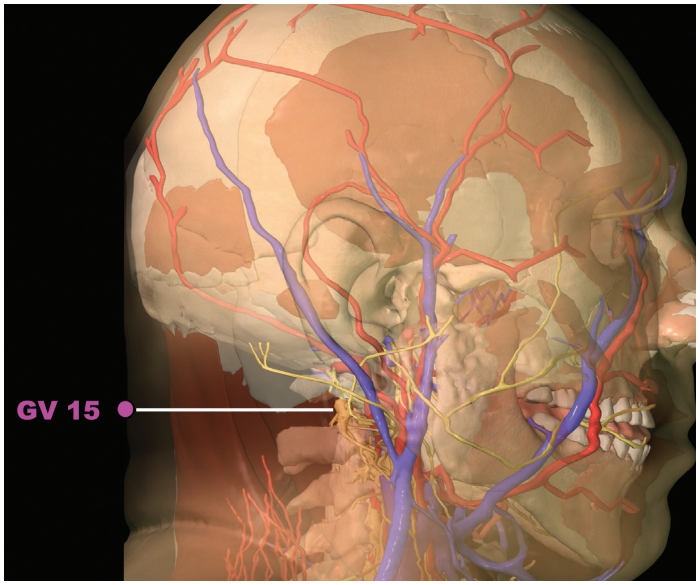

Figure 14-42. The distance from the skin surface to the spinal cord depends on the muscularity and size of the patient. This lateral view as well as the cross-section in Figure 14-43 depicts the depth of muscular, vascular, and neural features from the skin surface. However, anatomy varies between individuals; caution and safety are paramount.

Craniotomies with midline approaches may also damage or irritate the TON and cause occipital neuralgia after suboccipital approaches. Scar tissue envelops the nerve, compressing its branches; pain sometimes worsens with cervical motion and mounting myofascial restriction. Intraoperative traction applied to deeper facet branches of the TON during midline craniotomy damages its deeper facet branches. Acupuncture and related techniques carefully at BL 10, GV 15, and GV 16 can release tension in this region and neuromodulate the TON.

Brain imaging researchers studying acupuncture at GV 15 found that stimulation at this location may improve certain language disorders by activating certain language areas such as the left superior temporal gyrus.[15] Additionally, GV 15 stimulation may neuromodulate hypoglossal nerve (CN XII) function. Neuroanatomically, after the hypoglossal nerve exits the hypoglossal nucleus in the medulla, it travels through the hypoglossal canal and courses alongside the inferior ganglion of the vagus nerve at about the level of GV 15. It crosses the ventral surface of the transverse process of C1, making it vulnerable to injury upon hyperextension of the craniocervical junction. Along its course, it runs adjacent to the superior cervical sympathetic ganglion and arrives at the tongue to supply motor function.

The cisterna magna, or cerebellomedullary cistern, shown in Figure 14-43, contains the vertebral artery, the origin of the posterior inferior cerebellary artery, the choroid plexus, and cranial nerves IX, X, XI, and XII. Given that cranial nerves V, VII, IX, X, XI, and XII are involved in both swallowing and speech,

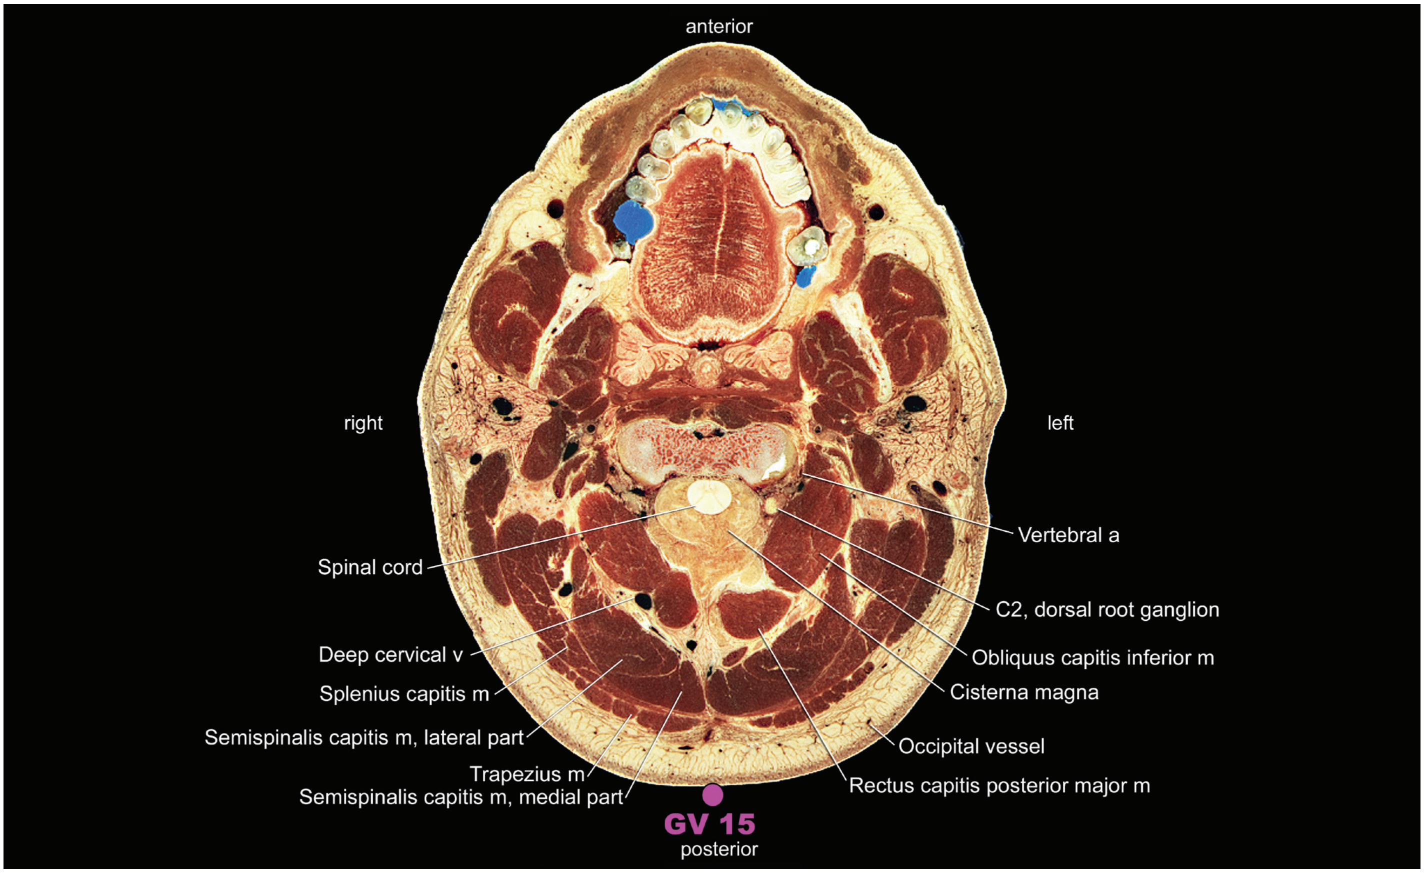

Figure 14-43. GV 15 has several other names in addition to "Gate of Muteness". They include: "Loss-of-Voice Gate", "Tongue Root", "Tongue Swelling", "Opposite the Tongue", "Tongue's Horizontal", "Tongue Repression", and "Repressed Tongue". This cross-section illustrates the way in which GV 15 and the tongue share the same horizontal plane, as described by its alternate names. This image also reveals the proximity of the rectus capitis posterior major and obliquus capitis inferior to the cisterna magna, highlighting the potential for myodural contiguity.

it follows that excessive pressure placed on the suboccipital region may compress one or more of these nerves coursing within the cisterna magna and cause temporary or prolonged dysphagia and/or dysarthria.

Vessels

- **Posterior external vertebral venous plexus:** This venous plexus is formed by the spinal veins along the vertebral column, outside of the vertebral canal. Veins from the vertebral bodies usually drain into the internal vertebral venous plexus, but they may drain into the anterior and posterior external vertebral venous plexuses in addition to the internal one. Because the veins in the epidural venous plexus inside the vertebral column lack valves, they can serve as a collateral route for return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. That is, the epidural venous plexus communicates not only with the lumbar veins of the inferior vena caval system, but also with the azygous system of veins that constitute part of the superior vena caval system. The azygous system of veins links the various venous segments throughout the thoracic, lumbar, and sacral regions.
- **Anastomosis between right and left occipital arteries:** Arising from the external carotid artery, each occipital artery courses along a groove in the base of the skull, and ends in the posterior portion of the scalp.
- **Anastomosis between right and left occipital veins:** The occipital veins typically drain into the suboccipital venous plexus, which drains into the vertebral vein and the deep cervical vein, but occasionally it may drain into the internal jugular vein.
- **Deep cervical artery (from the costocervical trunk, which arises from the subclavian artery):** Supplies the deep cervical muscles.
- **Deep cervical vein:** Receives tributaries from the plexuses around the spinous processes of the cervical vertebrae, and terminates in the lower part of the vertebral vein.

Clinical Relevance: Deep cervical vessels, seen in Figure 14-43 are vulnerable to damage with cervical spinal surgery[16] but also by acupuncture. Employ caution when needling this zone!

Veins of the epidural venous plexus lack valves. As such, they can serve as a collateral route paralleling the main caval route. This establishes another route of return of abdominopelvic venous blood if the inferior vena cava becomes blocked or ligated. This extensive network of freely communicating, valveless, venous channels also permits the metastatic spread of certain tumors. Research indicates that blood flow increases through the vertebral venous plexus as a consequence of increased intra-thoracic or intra-abdominal pressure, as when coughing, straining, or performing certain internal martial arts techniques. In the case of cancer, these passageways could serve as a conduit for metastatic tumor cells to deposit in the vertebrae, though additional factors likely influence the distribution of metastases, including the favorability of the target tissues to growth of metastatic cells and the presence of specific tumor-supportive substances.

Indications and Potential Point Combinations

- **Headache:** GV 15, BL 10, GV 20, Yintang (GV 24.5), LI 4, GB 20, GB 21, local tender trigger points.
- **Neck pain and stiffness:** GV 15, GV 14, GB 21, GB 20, BL 9, BL 10, pertinent trigger points.
- **Epistaxis:** GV 15.
- **Seizures:** GV 15, BL 10, GV 20, ST 36, LR 3, KI 3, ST 40.
- **Anxiety, agitation, depression:** GV 15, GV 20, CV 17, PC 7, ST 36.
- **Post–stroke aphasia, aphonia:** GV 15, CV 23, ST 36, GV 20.
- **Post-traumatic hypoglossal nerve dysfunction:**[2] GV 15, GV 16, BL 10, SI 17, CV 23, CV 24.
- **Post-craniotomy occipital neuralgia:** Laser therapy to BL 10, GV 15, GV 16, GB 20.

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis.**[3]
- Occipital nerve stimulation has gained acceptance as a treatment for **refractory primary headache.**[4]
- Acupuncture at GV 14, GV 15, and other points in addition to patient education **improved hearing threshold** by more than 20 dB.[17]
- Acupuncture for **aphasia** after stroke frequently involves GV 15, SP 6, Nos. 1 through 3 language sections on the scalp, GB 20, HT 5, Yuye, Jinjin, CV 23, and PC 6, and GV 20.[18]

GV 16

Feng Fu "Palace of Wind" "Wind Mansion"

On the nuchal region, on the dorsal midline, in the depression below the external occipital protuberance. Located approximately 1 cun within the caudal hairline, if one exists.

Caution: Avoid deep insertion.[1]

Brain tissue or vessel damage may result.

Withdraw needle if patient reports feeling an electric shock.

Deep needling may cause acute intracranial hemorrhage or other serious neurologic injury.[2]

Connective Tissues

- **Ligamentum nuchae (Nuchal ligament):** This strong median ligament, otherwise known as a "intervertebral syndesmosis", merges with the supraspinous ligament in the neck and extends from the external occipital protuberance to the spinous process of C7.[11] This bilaminar, fibroelastic, intermuscular septum sits between several paired muscles at the dorsal cervical midline. The nuchal ligament likely assists with head stabilization and maintenance of the lordotic curvature of the cervical spine. Continuity along the midline between the nuchal ligament and the caudal spinal dura at the atlanto-occipital and atlanto-axial segments is controversial.[3,4]

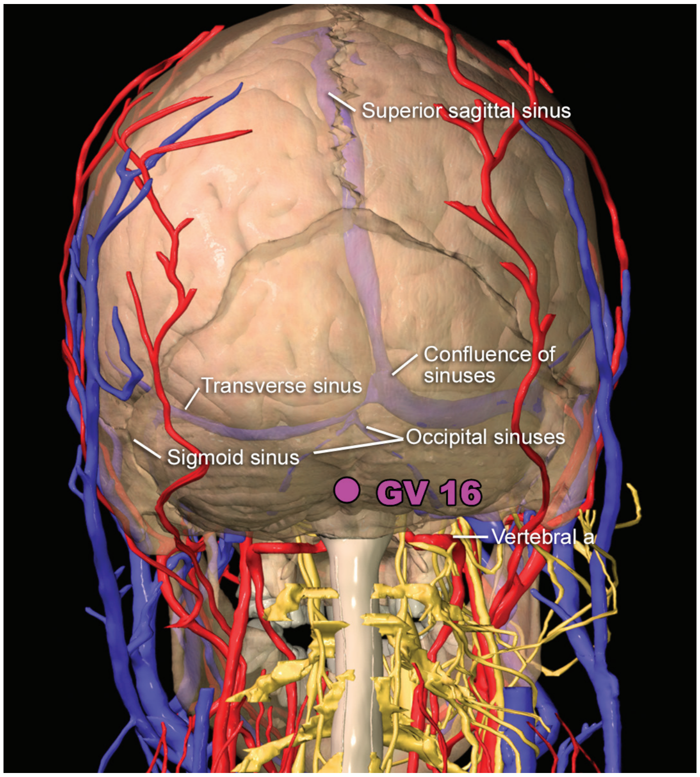

Figure 14-44. This image reveals the connection between GV 16 and the dural venous sinuses. Most notably, GV 16 resides near the occipital sinus, the smallest of all the sinuses. Usually, humans have a single occipital sinus but this individual had a small network. Small venous channels around the foramen magnum (where the spinal cord exits the skull) join the terminal portion of the transverse sinus. Here, the conjoined occipital sinuses drain into the left transverse sinus. It is not uncommon for the confluence of sinuses to occur off the midline, usually to the right, as shown. The connection between the occipital sinus(es) and with the posterior internal vertebral venous plexus is where cerebrospinal venous system transitions from spinal to cranial vascular structures.

- **Posterior atlanto-occipital (PAO) membrane:** This membrane (also known as a ligament) attaches to the foramen magnum and the caudal arch of the atlas. It serves as a canopy for the spinal cord exiting the foramen magnum. An acupuncture needle should never encounter the PAO membrane.

Clinical Relevance: Ossification of the nuchal ligament (ONL) results from the gradual calcification of fibroelastic tissue. Stiffening the nuchal ligament reduces active range of motion in neck flexion and extension. Patients with prominent ONL on radiograph may exhibit more severe cervical radiculopathy and degenerative changes in the spine.[12] Encouraging patients to safely pursue active range of motion exercise for the neck should aid in maintaining flexibility within the nuchal ligament and comfort in the neck. Reducing tension and pain in the neck with acupuncture and related techniques supports patients in these efforts and may also confer benefit to the nuchal tissue itself.

Repetitive motion injury or irritation of the nuchal ligament can predispose patients to develop of painful osseous nodules considered "calcinosis circumscripta".[13] Patients with calcinosis circumscripta of the nuchal ligament usually exhibit neck pain and a history of cervical trauma. These metaplastic localized modifications of nuchal ligament tissue most often develop in the higher mobility regions of C4-C7.

The free border of the PAO membrane arches over the vertebral artery and the suboccipital nerve. Conceivably, stiffening of the PAO membrane could compress these neurovascular elements. More importantly, perhaps, given that the membrane adheres to both dura mater and suboccipital muscles, it provides a vehicle by which strain and traction transfer between the central nervous system and the myofascia of the neck.[14] This connective tissue bridge would allow the rectus capitis posterior minor muscle to limit dural infolding during head and neck extension. At the same time, however, this myodural connection acts as a source of pain and dysfunction. Fortunately, one can treat this site (but always gently and safely) to alleviate stress and proprioceptive disturbances.

Muscles

- **Rectus capitis posterior minor (RCPm) muscle:** This small proprioceptor for the head arises from the tubercle on the posterior arch of the atlas and inserts onto the medial portion of the inferior nuchal line of the occipital bone, as well as onto the surface between the inferior nuchal line and the foramen magnum. Some fibers attach to the spinal dura and the posterior atlanto-occipital (PAO) membrane (ligament). Tendinous fibers from the medial and deep parts of the RCPm muscle are continuous antero-inferiorly with the posterior cervical spinal dura, the PAO membrane joins with the RCPm fascia, tendon, and perivascular sheaths, and the PAO membrane fuses with the spinal dura but not the atlas in the antero-inferior portion.[5] The double-layered PAO membrane extends laterally between the RCPm muscle and the vertebral vascular sheath. In so doing, the PAO membrane anchors the RCPm to the vertebral vascular sheath. The membrane splits on the medial aspect to accommodate the external vertebral plexus and surrounding connective tissue; its deep layer fuses with the spinal dura, as mentioned earlier. The PAO membrane sits at the transition zone between the cranial and spinal dura, perivascular sheaths related to the internal and external vertebral venous plexuses and marginal dural sinus, and the deep layer of the RCPm fascia. See Figure 14-47C to examine these relationships more in-depth.

- **Rectus capitis posterior major muscle:** Provides proprioceptive input regarding head orientation and dural tension along with its partner, the rectus capitis posterior minor muscle. Also extends the head at the upper cervical spine.
- **Trapezius muscle:** Fibers of the cranial, or superior, part of the trapezius elevate thescapula (i.e., when shrugging the shoulders).
- **Semispinalis capitis muscle, medial part:** Extends the head.

Clinical Relevance: The fossa defined by the superior and inferior nuchal lines houses several muscular attachments reserved for superficial movers of the head including the occipitalis, trapezius, sternocleidomastoid, semispinalis capitis, and the splenius capitis muscles. More deeply, between the inferior nuchal line and the foramen magnum reside the rectus capitis posterior minor, rectus capitis posterior major, and obliquus superior. These small structures provide subtle head movements and, more importantly, proprioception. Refer to Figures 14-46 and 14-47A for further exploration of these myofascial relationships to GV 16.

The discovery of connections between suboccipital muscles (i.e., the rectus capitis posterior major and minor as well as the obliquus capitis inferior muscles[15]) and the dura explains a common etiology of cervicogenic headache.[16] Myodural connections form of soft tissue bridges in the atlantoaxial interspace level with GV 15 and the atlantooccipital interspace level with GV 16. See Figure 14-47C.

The soft tissue adjoining muscle to dura harbors proprioceptive neurons, implicating suboccipital muscles in aiding the brain in its control over head position and dural tension.[17] Researchers speculate that myodural biofeedback "may play a role in maintaining the integrity of the subarachnoid space and, subsequently, cerebrospinal pressure. If this mechanism does exist, its failure may result in a variety of clinical manifestations including those arising from increasing dural tension, namely cervicogenic headaches."[18] On the other hand, weakness or atrophy in the suboccipital muscles may lead to hypermobility and irritation of local nerve fibers.

Patients with suboccipital trigger points express tenderness to palpation, referred pain evoked by sustained pressure, and pain worsening when they actively extend the upper cervical spine. Trigger points in the suboccipital muscles tend to create pain perceived as penetrating the skull in a poorly localizable fashion. Patients may first complain that the entire head aches, but upon further questioning and examination, tenderness to palpation may center on a unilateral suboccipital focus. In comparison, trigger points in the upper semispinalis capitis muscle adjacent to GV 15 incite radiating pain to the ipsilateral temporal region with diffuse pain that wraps around the head like a crown.

While some have excised the myofascial bridge to alleviate chronic headache,[19] nonsurgical approaches should certainly be tried first, including manual therapy, laser therapy, and cautious acupuncture.

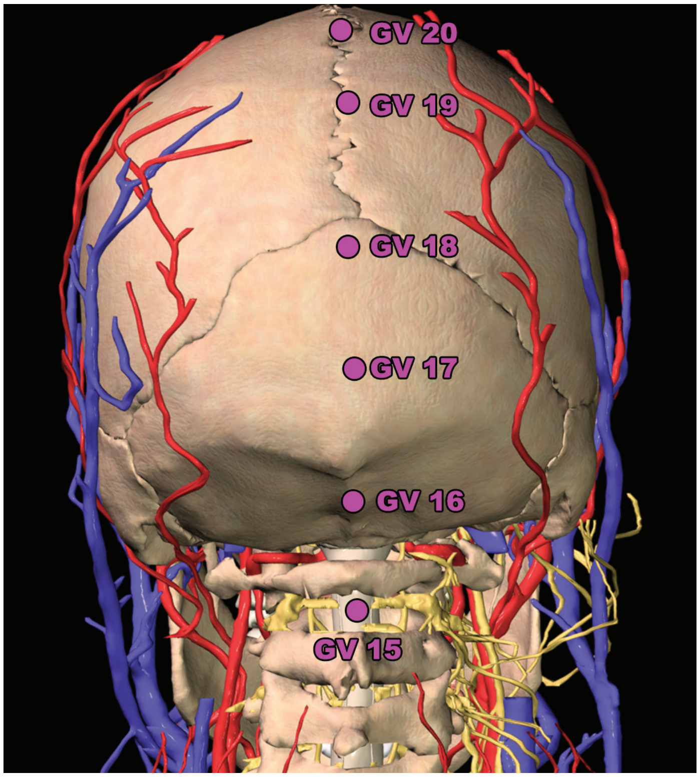

Figure 14-45. One finds GV 16 in a depression just inferior to the external occipital protuberance as shown here. Nearby GV points are also shown along the midline.

Prolonged nociceptive input from trigger points in the head and neck invoke central sensitization in the cervical cord and trigeminal nucleus caudalis. View the spinal nucleus of the trigeminal nerve in Figure 14-47A. The pars caudalis is the most caudal portion of the spinal nucleus. Pain signals may relay between the suboccipital region and muscles of mastication.[20,21] Acupuncture and related techniques may aid in breaking this cycle counteracting chronic pain in the head and neck.

Pain in the occipital regions can also arise from trigger points in the multifidi, levator scapulae, splenius cervicis, and infraspinatus muscles. Restriction in the soft tissues of the neck places pressure on large, vital neural, vascular, and glandular components, increasing the risk of producing pain and potentially negatively impacting glandular function.

Cervicogenic dizziness may result from abnormal afferent activity in cervical muscles, especially those in the suboccipital section of the spine.[22] Abnormal input reaches vestibular nuclei from dysfunctional proprioceptors of the upper cervical region, causing neck pain and tension that aggravate dizziness. Dizziness worsens muscle spasm and a maladaptive positive feedback loop ensues where muscle tension also exacerbates the feeling of being dizzy. Patients may provide a history of looking upward for a long period of time just prior to becoming dizzy. If one suspects a cervicogenic cause of disequilibrium and other causes have been ruled out, manual therapy, laser, and cautious acupuncture at GV 16, GV 15, BL 10, and other regional points may provide relief.

Figure 14-47A exposes the relationship between GV 16, the rectus capitis posterior major and minor muscles, along with the semispinalis capitis muscle. The presence of deep cervical veins beneath GV 16 should give one pause when considering needling

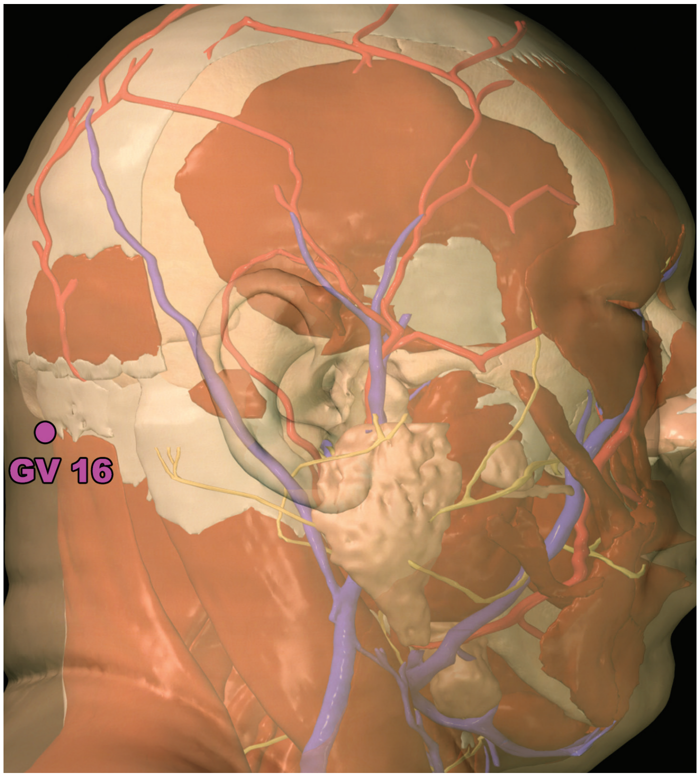

Figure 14-46. The names "Palace of Wind" and "Wind Mansion" for GV 16 refer to the metaphorical condition of "wind invasion" in Chinese medicine. "Wind disorders" include those incited by windy weather (called "exogenous wind") that cause necks to stiffen and noses to run as well as neurologic ailments. "Endogenous wind", according to pre-scientific metaphorical precepts, underlies the onset of various neurologic disturbances such as stroke, facial nerve injury, vertigo, and headache. The fact that GV 16 sits adjacent to several muscles and nerves helps to explain its indication for neck pain while its proximity to the cerebrum and venous sinuses attests to its support of brain function.

beyond the semispinalis capitis. Manual therapy and/or laser treatment would provide safer means of addressing trigger point pathology than would needling deep suboccipital structures.

Nerves

- **Third ("Least") occipital nerve, or TON (C3):** Innervates the skin of the medial occipital and cervical regions. This dorsal ramus of the C3 spinal nerve separates into a complex system of branches after emerging from the articular pillar of the C3 vertebra. It divides into medial and lateral branches, with the medial further separating into deep and superficial divisions.[23]
- **Greater occipital nerve, or GON (C2, (C3)):** Supplies cutaneous sensation to the posterior scalp. Arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[24] (The occipital artery appears in Figure 7-17 lateral to BL 9.) As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.
- **Spinal nerves C2-C3, dorsal rami:** Innervate the posterior cranial fossa.
- **Spinal nerves C2-C4, dorsal rami:** Innervate the semispinalis capitis muscle.
- **Spinal accessory nerve (CN XI):** Provides motor control to the trapezius muscle.
- **C3 and C4 spinal nerves:** Provide pain sensation and proprioceptive function to the trapezius muscle.

Clinical Relevance: Neuroanatomically, nerves supplying GV 16 communicate with vagal, trigeminal, and upper cervical spinal cord pathways. Clinical applications for GV 16, "Wind Mansion" nearly exclusively relate to intracranial or craniocervical pathology. Indications include headache, seizures, vertigo/dizziness, loss of consciousness, cerebrovascular accident (CVA, stroke), agitation, anxiety), pain (cranial, cervical), upper respiratory conditions (rhinitis, sinusitis, epistaxis), and musculoskeletal (somatic) dysfunction. Structure-function connections between the nerves supplying GV 16, associated reflexes, and physiology influenced justify many of these considerations for clinical usage.

Suboccipital structures connect either directly or through reflexes to the upper cervical nerves, the vagus, trigeminal, and upper thoracic sympathetic nerves.

Pain sensation in the posterior fossa and its vasculature travels through a nerve called the recurrent meningeal nerve. This nerve ferries general somatic afferent fibers from the superior vagal ganglion and meningeal rami of the upper three cervical nerves, with C2 predominating. Sympathetic fibers from the superior cervical sympathetic ganglion fibers travel with the recurrent meningeal nerve into the posterior fossa and provide vasomotor control to vessels housed therein.

The recurrent meningeal nerve courses along the walls of the sigmoid sinus to supply the dura of the petrous surface of the temporal bone. Branches visit the transverse sinus on their way to the falx cerebelli, occipital sinus, and dura of the suboccipital cerebellar surface.

Thus, the vagus and upper cervical nerves (comprising the GON and TON) are responsible for producing headache pain on the back of the head[25] and the nauseating malaise associated with vagal irritation. On the other hand, the trigeminal nerve accounts for much of the cranial region headache. That said, both sources can spur the other on by means of the trigeminal nucleus caudalis, seen in Figure 14-47A about midway between the rostral and caudal aspects of the head.

The caudal scalp receives sensory nerve supply from the greater occipital nerve (GON). Crosstalk between the GON and the trigeminal nerve and windup in the trigeminocervical complex in the brainstem and cervical cord supports the inclusion of GV 16 in point protocols addressing intracranial and extracranial sources of discomfort. Stimulation of the GON can reduce pain from headaches that arise in trigeminal nerve territory, likely through mechanisms involving trigemino-cervical convergence at the level of the trigeminal nucleus caudalis.[26]

Nerves in the suboccipital region may become entrapped in the layers of myofascia deep to GV-16, also shown by Figure 14-47A. Nerve entrapment worsens pain and myofascial restriction.

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[27] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[28] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[29,30]

In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[31] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[32] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[33]

Third occipital nerve (TON): This dorsal branch of the 3rd cervical spinal nerve must make its way through several layers of deep nuchal musculature, that may compress or otherwise irritate it. This nerve likely produces occipital neuralgia more than has been previously recognized.[34]

Occipital neuralgia originating from TON irritation mimics GON neuralgia. The superficial medial branch of the C3 spinal nerve, also called the 3rd or least occipital nerve, travels around the dorsolateral surface of the C2-3 zygapophyseal (facet) joint that it supplies. It branches at about BL 10. While facet joints caudal to C2-3 receive innervation by the dorsal rami above and below the joint, the C2-3 facets only receive TON innervation. After supplying the facet joint, the TON continues on to supply the semispinalis capitis muscle, traveling deeply along this muscle until it sends a communicating branch to the greater occipital nerve. The risk of third occipital neuralgia increases as a result of its vulnerability to entrapment at the level of the intervertebral disk behind the intervertebral joints. Osteophytes in these joints can produce nerve compression and chronic headache that may remain undiagnosed as a result of clinicians' unfamiliarity with this specific nerve entrapment syndrome.

Cervical zygapophyseal joints cause chronic neck pain and headache in up to half of patients. Facet joints receive innervation from the medial branches of the spinal nerves C3 to C7; each nerve supplies the joint above and below. This calls for treatment not only on the head but also throughout the neck as palpation indicates and symptom manifestations warrant.

Although percutaneous radiofrequency ablation (RFA) has become an accepted nonsurgical modality for chronic neck pain, adverse outcomes may occur. RFA of the least (3rd) occipital nerve and the C2-C4 facet joints has led to "dropped head syndrome" in which the patient became unable of extending her neck, inducing a debilitating complication.[35] While acupuncture and related techniques may not be able to repair nerves completely destroyed by RFA, the risk of permanent disability emphasizes the need to address pain and functional compromise with safe and effective approaches such as acupuncture and related techniques before pursuing modalities that pose risk of irreversible damage.

Midline craniotomies may also damage or irritate the TON and cause neuralgia. Scar tissue may envelop the nerve and compress its branches; pain can worsen with cervical motion and mounting myofascial restriction. Intraoperative traction may damage deeper facet branches of the TON. Acupuncture and related techniques at BL 10, GV 15, and GV 16 can release tension and neuromodulate the TON.

Avoid placing excessive pressure on the suboccipital region during massage or soft tissue manipulative therapy. The cisterna magna, or cerebellomedullary cistern, shown in Figure 14-43 and Figure 14-47A, contains the vertebral artery, the origin of the posterior inferior cerebellar artery, the choroid plexus, and cranial nerves IX, X, XI, and XII. Given that cranial nerves V, VII, IX, X, XI, and XII are involved in both swallowing and speech, it follows that excessive pressure placed on the suboccipital region may compress one or more of these nerves coursing within the cisterna magna and cause temporary or prolonged dysphagia and/or dysarthria.

Vessels

- **Anastomosis between right and left occipital arteries:** Arising from the external carotid artery, each occipital artery courses along a groove in the base of the skull, and ends in the posterior portion of the scalp.
- **Anastomosis between right and left occipital veins:** The occipital veins typically drain into the suboccipital venous plexus, which drains into the vertebral vein and the deep cervical vein, but occasionally it may drain into the internal jugular vein.

Clinical Relevance: The occipital artery is often a main feeding artery in cases of intracranial dural arteriovenous fistulae.[36] Also, blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[37] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

Venous pathways associated with the GV channel extend from the brain to pelvic organs as the cerebrospinal venous system, or CSVS.[38] At GV 16, the vertebral venous plexiform network that coursed throughout the spine transforms into cranial dural venous sinuses. These, in turn, anastomose with veins on the scalp, skull (as diploic veins), and face.

Analogies between the vertebral venous plexuses and the intracranial dural venous sinuses have been drawn. For example, the anterior internal vertebral plexus in the spine resembles the superior and inferior petrosal, cavernous, and lateral sinuses in the head.[39] The posterior internal vertebral venous plexus joins the midline sinus system of the head and there manifest as the superior sagittal, straight, and occipital sinuses.

Figure 14-47A. Many of the myofascial elements that cause headache appear in this cross-section, from the rectus capitis posterior major and minor to the larger, stronger, trapezius and semispinalis capitis muscles and more. Even though acupuncture deactivates trigger points well, note the presence of large veins in the region deep to GV 16. This should cause pause before one decides to needle suboccipital sites deeply. Instead, it is safer to consider myofascial release, massage, and laser therapy for access to and relief of deep dorsal cervical myofascial pathology. That said, avoid applying sustained pressure below the occiput that may injure the brainstem or emanating nerves.

of intervertebral foramina, allowing communication between intra- and extra-cranial veins. In fact, one could view the venous system of the head, with its extended intracranial, extracranial, and intraosseous (diploic) network, as a single venous plexus.

Indications and Potential Point Combinations

- **Sinus pain:** GV 16, BL 2, GB 14, ST 3, GV 20, LI 4, ST 44.
- **Cervical somatic dysfunction:** GV 16, BL 10, GB 20, GV 14, GB 21, local trigger points.
- **Cervicogenic headache:** GV 16, BL 10, GV 24.5 (Yintang), GV 20, local tender, latent, and active trigger points.
- **Vertigo, dizziness:** GV 16, GB 20, GB 21, GB 34, BL 10, GV 20, temporalis trigger points.

Evidence-Based Applications

- Electroacupuncture at GV 11 and GV 16 suppressed both **hyperemia** and excessive glutamate release during and after transient ischemia in gerbils. Both hyperemia and excessive glutamate after ischemia may be important factors contributing to brain damage via reperfusion injury. This suggests that such suppression contributes to the **neuroprotective** effects of electroacupuncture in cases of ischemic brain damage.[6]
- Electroacupuncture at GB 20 and GV 16 prior to **craniocerebral tumor** surgery may supply Neuroprotective influences for brain tissue.[40]
- Greater occipital nerve stimulation has emerged as a viable treatment for headache due to **occipital neuralgia.**[7]
- Evidence for peripheral sensitization as the etiology of **migraine** pain shows that at least in some cases, the headache phase depends on nociceptive input from perivascular sensory nerve terminals.[8] Nerve terminals related to arteries seem to have more of an impact on pain generation than those from veins. All of the arteries of the scalp (the superficial temporal, posterior auricular, occipital, supraorbital, and frontal arteries) convey pain sensation that arises from various causes, including distension. However, scalp veins do not demonstrate the same sensitivity to pain. Most notably, activated nociceptive periarterial sensory nerve terminals may produce migraine pain along with abnormal central interpretation of normal sensory input within the trigeminal sensory system.
- Some patients with multiple sclerosis exhibit chronic **cerebrospinal venous** insufficiency, characterized by abnormal venous hemodynamics linked to multiple extracranial venous strictures.[9] Where these venous obstructions occur determines the clinical course of the disease. If stimulating GV points can normalize vasomodulatory input, perhaps stimulation along this channel and at affected extracranial sites can influence venous drainage of the central nerve system and benefit MS patients.
- Electroacupuncture at GV 16 and GV 8 improved neuronal regeneration in the striatum of adult rat brains after experimentally-induced **stroke.**[10]
- Electroacupuncture at GV 20, Yintang, GV 16, GV 14, GB 20, PC 6, and SP 6 provided greater clinical improvement than did paroxetine alone for patients with **major depressive disorder.**[41]

GV 17

Nao Hu “Brain’s Door”

On the midline of the occipital region, in the depression above the external occipital protuberance, 1.5 cun superior to GV 16. Located one-fourth the distance from GV 16 to GV 20. See Figure 7-17 to examine the relationship between GV 17, BL 9, and GV 16.

Fascia

- **Galea aponeurotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. (See Figure 14-49.)

Clinical Relevance: GV 17 can become tender to palpation with occipitofrontalis tension (e.g., in cases of tension headache) that results in traction on the epicranial aponeurosis. GV 17 also exhibits tenderness to palpation in patients with migraine and chronic neck pain. Trigger point pathology in other muscles of the head and neck also refer pain to the occiput. These include the trapezius, sternocleidomastoid, semispinalis, splenius, suboccipital group, occipitalis, digastric and temporalis.

Nerves

- **Third (“Least”) occipital nerve, or TON (C3):** Innervates the skin of the medial occipital and cervical regions. This dorsal ramus of the C3 spinal nerve separates into a complex system of branches after emerging from the articular pillar of the C3 vertebra. It divides into medial and lateral branches, with the medial further separating into deep and superficial divisions.[2]
- **Greater occipital nerve, or GON (C2, (C3)):** Supplies cutaneous sensation to the posterior scalp. Arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic “sling”, close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[3] (The occipital artery appears in Figure 14-49 lateral to GV 17.) As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.
- **Spinal nerves C2-C3, dorsal rami:** Innervate the posterior cranial fossa.

Clinical Relevance: Clinical indications for GV 17, “Brain’s Door” nearly exclusively relate to intracranial or craniocervical pathology. Indications include headache, seizures, vertigo/dizziness, loss of consciousness, cerebrovascular accident (CVA, stroke), agitation, anxiety), pain (cranial, cervical), visual disturbances, vestibular disorders, and sinusitis.

Pain sensation in the posterior fossa and its vasculature travels through a nerve called the recurrent meningeal nerve. This nerve ferries general somatic afferent fibers from the superior vagal ganglion and meningeal rami of the upper three cervical nerves, with C2 predominating. Sympathetic fibers from the superior cervical sympathetic ganglion fibers accompany the recurrent meningeal nerve into the posterior fossa and provide vasomotor control to vessels housed therein.

The recurrent meningeal nerve makes its way along the walls of the sigmoid sinus to supply the dura of the petrous surface of the temporal bone. Branches visit the transverse sinus on their way to the falx cerebelli, occipital sinus, and dura of the suboccipital cerebellar surface.

The upper cervical nerves (i.e., the GON and TON) and the vagus nerve are responsible for producing occipital headache,[4] nausea, and malaise. Trigeminal nerve irritation usually relates to more rostral head pain, but each of these nerves interacts and can aggravate each other through their connections in the trigeminal nucleus caudalis, seen in Figure 14-47A about midway between the rostral and caudal aspects of the head.

Crosstalk between the GON and the trigeminal nerve can contribute to windup in the trigeminocervical complex of the brainstem and cranial spinal cord. Neuromodulation at GV 17 may aid in reducing windup and regional nerve compression.[5]

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[6] While surgical implantation of nerve stimulators has been tried for patients with refractory

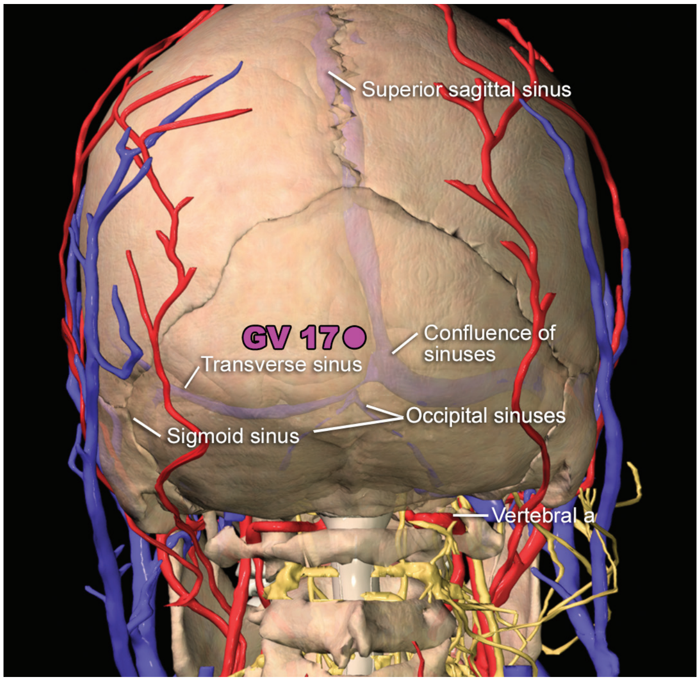

Figure 14-48. GV 17 resides on the occipital bone resembles a doorway to the brain, hence the name “Brain’s Door”. If it did, it the occiput would lower and admit entry to the occipital lobe and various venous sinuses. The superior sagittal dural venous sinus, shown here through the semi-transparent cranium, begins at the foramen cecum where it receives a vein from the nasal cavity. It courses caudad along the midline, traversing the frontal, parietal, and occipital lobes. When it reaches the internal occipital protuberance, it deviates, often to the right, and then bifurcates into two transverse sinuses. The upside-down “T” formed by transverse sinuses, intersects with the superior sagittal sinus at GV 17 near the confluence of sinuses. In addition, the confluence of sinuses connects with the straight and occipital sinuses. The vertebral artery appears here as a reminder of the risk of stroke by dint of upper cervical high-velocity thrusting that traumatizes the artery as it makes a right-angle turn over the atlas.

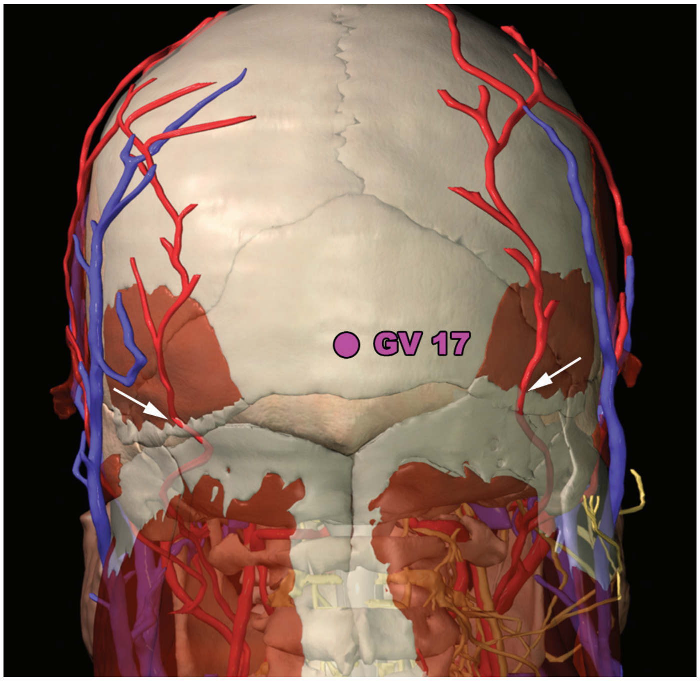

Figure 14-49. Myofascial tension in epicranial structures can compress occipital arteries and nerves. Where they intersect or intertwine, occipital artery pulsations may induce nerve irritation and cause migraine.[17] The arrows in this image show the occipital artery on each side as it emerges from the fascial insertion of the trapezius muscle at the superior nuchal line. This is a common zone of compression for the greater occipital nerve (not shown), both by myofascia and an overlying occipital artery.[18]

headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[7] acupuncture offers a much less traumatic intervention.[8,9]

Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia. Some patients experience migraine in conjunction with occipital neuralgia. In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[10] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[11]

As the third (or least) occipital nerve makes its way through layers of nuchal musculature, it may experience compression, leading to a type of occipital neuralgia more common than previously recognized.[12] TON neuralgia mimics GON neuralgia. The risk of third occipital neuralgia increases as a result of its vulnerability to entrapment at the level of the intervertebral disk behind the intervertebral joints. Osteophytes in these joints can produce nerve compression and chronic headache that may remain undiagnosed as a result of clinicians' unfamiliarity with this type of nerve entrapment syndrome.

Figure 14-50 shows the occipital lobe deep to GV 17. This lobe houses the primary visual cortex. Lesions in the occipital lobe can cause visual hallucinations and visual field defects. Flashing lights or images with multiple bright colors (like looking into a scanner as it shines its light onto a page) can trigger occipital lobe seizures. These "photosensitivity seizures" are associated with "flicker stimulation" experienced when watching television, playing video games, or the like.

Neuromodulation at GV 17 may aid in reducing irritability of an occipital lobe epileptic focus. However, while needle acupuncture must work indirectly on the brain, laser therapy influences brain function both directly and indirectly. That is, laser therapy units set at the appropriate power and wavelength deliver photonic stimulation capable of modifying brain function.[13,14,15] Selecting sites for laser photobiomodulation by means of the acupuncture framework[16] standardizes loci and utilizes a system already investigated for its structure-function characteristics.

GV 17 neuromodulation may also impact cerebellar function; their relationship appears in Figure 14-50. The cerebellum refines motor control and influence memory, attention, language, and emotional responses. It contains centers that support balance and spatial orientation, thereby suggesting indications of GV 17 for vestibular dysfunction and disequilibrium, along with GB 20, BL 10, and GV 20.

Vessels

- **Anastomosis between right and left occipital arteries:** Arising from the external carotid artery, each occipital artery courses along a groove in the base of the skull, and ends in the posterior portion of the scalp.
- **Anastomosis between right and left occipital veins:** The occipital veins typically drain into the suboccipital venous plexus, which drains into the vertebral vein and the deep cervical vein, but occasionally it may drain into the internal jugular vein.
- **Emissary veins:** These veins connect the dural venous sinuses with the extracranial veins. Emissary veins lack valves, and blood may flow in either direction, though usually its flow is from the brain outward. Emissary veins vary in size and number. Children have a frontal emissary vein that may persist in some adults.

The frontal emissary vein connects the superior sagittal sinus with the frontal sinus and nasal cavities. Parietal emissary veins may occur in pairs, passing through the parietal foramina in the calvaria and allowing flow between the superior sagittal sinus and the veins of the scalp. Occipital or posterior auricular veins connect with the sigmoid sinus via the mastoid emissary veins, which course through the mastoid foramina.

Clinical Relevance: The occipital artery commonly intersects with the greater occipital nerve. Pulsations in the artery may irritate the nerve and produce head pain. Note in Figure 14-49 how the occipital artery emerges from the fascial insertion of the trapezius muscle at the superior nuchal line. This is one site of neurovascular compression for the greater occipital nerve and occipital artery. Tension in the epicranial aponeurosis heightens the likelihood of headache. As such, GV 17 provides a locus for acupuncture, laser therapy, or soft tissue release of nerve and vessel entrapment.

The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear. Blood

from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

Parts of the cerebrospinal venous system (CSVS), i.e., the vascular basis of the GV channel, appear in Figures 14-48, 14-50, and 14-51. These include the dural venous sinuses and diploic veins as well as, indirectly, various extracranial veins such as the posterior auricular.

Indications and Potential Point Combinations

- **Tension headache:** GV 17, GV 20, GV 24.5 (Yintang), GV 14, temporalis trigger points, BL 10, GB 21, LI 4.
- **Vertigo, dizziness:** GV 17, GV 15, GB 8, GB 20, BL 10, LR 3, PC 6.
- **Visual processing disorders:** GV 17, GB 18, BL 9, LR 2, LR 3.

Evidence-Based Applications

- Scalp acupuncture at GV 20, GV 26, and GV 17, three needles in the temporal region, and points defined according to the Yamamoto New Scalp Acupuncture approach reportedly improved language development in children with **autism** in a pilot trial.[1]

GV 18

Qiang Jian "On Rigidity" "Unyielding Space"

On the midline of the occipital region, midway between GV 16 and GV 20. 1.5 cun rostral to GV 17.

Posterior Fontanelle (Babies and young children)

- The fibrous, membrane-covered gap that exists between the parietal bones and the occiput until it closes to become the lambdoidal suture.

Clinical Relevance: Caution with needling and acupressure is required when treating babies and toddlers due to the possible presence of an open posterior fontanelle at GV 18 or just rostral to the point. Usually, the posterior fontanelle closes early in the first year of an infant's life.

Connective Tissues

- **Skin:** This outer layer of the scalp consists of 5 layers: **S**kin, **C**onnective tissue (dense), **A**poneurosis, **L**oose connective tissue, and **P**ericranium. It ordinarily contains an abundant arterial supply as well as good venous and lymphatic drainage.
- **Dense connective tissue:** Comprises the thick and well-vascularized subcutaneous layer, richly supplied with cutaneous nerves. Lacerations of the scalp bleed profusely as a consequence of abundant arterial anastomoses. These arteries fail to retract when cut because the dense connective tissue in the scalp maintains patency of arterial walls.
- **Galea aponeurotica (epicranial aponeurosis):** This strong, tendinous sheet, or aponeurosis, covers the calvaria and connects the occipitalis, superior auricular, and frontalis muscles; the collective term for this structure is the "epicranius muscle".
- **Loose connective tissue:** Resides deep to the galea aponeurotica, creating spaces capable of distending with fluid during infection or following trauma.
- **Pericranium:** This external periosteum of the calvaria exhibits continuity with the fibrous tissue inhabiting the cranial sutures.

Clinical Relevance: Scalp needling requires caution; the loose connective tissue layer constitutes the "danger area of the scalp", as infection from this layer may enter the cranium by way of emissary veins that course through calvarial foramina.

Tissue at GV 18 can become tender to palpation with occipitofrontalis tension, as in tension headache, as well as migraine and chronic neck pain. Trigger point pathology in other muscles of the head and neck also refer pain to the occiput. These include the trapezius, sternocleidomastoid, semispinalis, splenius, suboccipital group, occipitalis, digastric and temporalis.

Nerves

- **Third ("Least") occipital nerve, or TON (C3):** Innervates the skin of the medial occipital and cervical regions. This dorsal ramus of the C3 spinal nerve separates into a complex system of branches after emerging from the articular pillar of the C3 vertebra. It divides into medial and lateral branches, with the medial further separating into deep and superficial divisions.[1]
- **Greater occipital nerve, or GON (C2, (C3)):** Supplies cutaneous sensation to the posterior scalp. Arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[2] As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases. See Figure 14-49 to examine this site more closely.
- **Spinal nerves C2-C3, dorsal rami:** Innervate the posterior cranial fossa.

Clinical Relevance: Clinical indications for GV 18, "Unyielding Space" include headache, seizures, anxiety, pain, visual disturbances, and generalized tension.

Pain sensation in the posterior fossa and its vasculature travels through a nerve called the recurrent meningeal nerve. This nerve ferries general somatic afferent fibers from the superior vagal ganglion and meningeal rami of the upper three cervical nerves, with C2 predominating. Sympathetic fibers from the superior cervical sympathetic ganglion fibers accompany the recurrent meningeal nerve into the posterior fossa and provide vasomotor control to vessels housed therein.

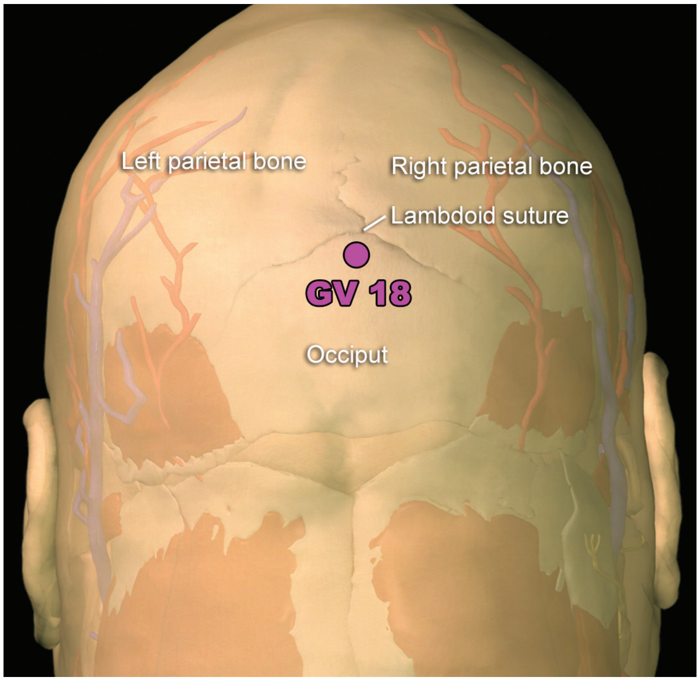

Figure 14-52. GV 18 lands adjacent to the lambdoid suture, i.e., the "lambda"-like suture created by the abutting occipital and parietal bones. This site feels hard and unyielding when palpated, explaining the names, "On Rigidity" and "Unyielding Space". The bone thickens here as well, shown by the cross-section in Figure 14-54.

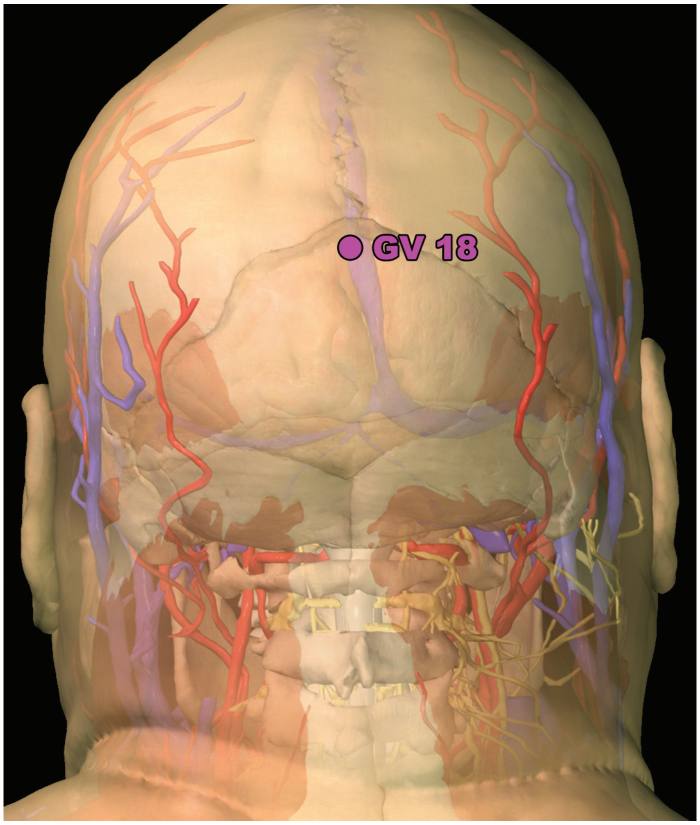

Figure 14-53. GV 18 relates not only to the lambdoid suture but also to the superior sagittal sinus. Thrombosis in any of the cerebral venous sinuses can cause rapidly worsening and severe headache or stroke-like symptoms.[14] Emergency attention is warranted.

The recurrent meningeal nerve makes its way along the walls of the sigmoid sinus to supply the dura of the petrous surface of the temporal bone. Branches visit the transverse sinus on their way to the falx cerebelli, occipital sinus, and dura of the suboccipital cerebellar surface.

When injured or dysfunction, the upper cervical nerves (i.e., the GON and TON) and the vagus nerve cause occipital headache,[3] nausea, and malaise. Trigeminal nerve irritation usually produces headache of a more rostral nature, but each of these nerves interacts and can aggravate the other by means of central nervous interconnections in sites like the trigeminal nucleus caudalis. This nucleus appears in Figure 14-47A about midway between the rostral and caudal limits of the skull. Crosstalk between the GON and the trigeminal nerve can also contribute to windup in the trigeminocervical complex. Neuromodulation through the GON by means of treatment at points like GV 18 can help patients with chronic, or refractory, migraine.[4]

Traumatic or degenerative upper cervical spinal disease predisposes patients to develop occipital neuralgia. Although some patients may experience both migraine and occipital neuralgia, in contrast to migraine, occipital neuralgia produces a characteristic paroxysmal, jabbing pain along the course of the nerve. The pain may be accompanied by reduced sensation or dysesthesia in the occiput.[5] The involved nerves become tender to palpation. Confirming the diagnosis with injection of local anesthetic near the GON can pinpoint and temporarily treat the neuralgia, but risk complications. These include injection of local anesthetic into the occipital artery, production of a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[6]

As the third (or least) occipital nerve makes its way through layers of nuchal musculature, it may also undergo compression. TON as a cause of occipital neuralgia occurs more commonly than previously recognized.[7] The risk of third occipital neuralgia increases as a result of its vulnerability to entrapment at the level of the intervertebral disk behind the intervertebral joints. Osteophytes in these joints can produce nerve compression and chronic headache that may remain undiagnosed as a result of clinicians' unfamiliarity with this type of nerve entrapment syndrome.

Figure 14-54 shows the occipital lobe deep to GV 18. This lobe houses the primary visual cortex. Lesions in the occipital lobe can cause visual hallucinations and visual field defects.

Flashing lights or images with multiple bright colors (such as those seen when looking into a scanner as it shines its light onto a page) can trigger occipital lobe seizures. These "photosensitivity seizures" stem from "flicker stimulation" as when watching television, playing video games, or the like.

Neuromodulation at GV 18 may aid in reducing irritability of an occipital lobe epileptic focus. While needle acupuncture indirectly alters brain function, laser therapy has the capacity to influence brain function directly as well. That is, photonic stimulation of suitable power and wavelength has been shown to stimulate recovery from injury.[8,9,10] Selecting sites for laser photobiomodulation by introducing acupuncture anatomy[11] standardizes loci and facilitates recognition of structures stimulated.

Vessels

- **Anastomosis between right and left occipital arteries:** Arising from the external carotid artery, each occipital artery courses along a groove in the base of the skull, and ends in the posterior portion of the scalp.
- **Anastomosis between right and left occipital veins:** The occipital veins typically drain into the suboccipital venous plexus, which drains into the vertebral vein and the deep cervical vein, but occasionally it may drain into the internal jugular vein.
- **Superior sagittal sinus:** Begins at the foramen cecum, located at the frontal crest of the frontal bone where it articulates with the ethmoid bone. The superior sagittal sinus drains from rostral to caudal along a groove running inside the frontal and parietal bones. Near the internal occipital protuberance, the superior sagittal sinus drains into the confluence of sinuses and continues with the transverse sinuses, often more closely affiliated with the right one than the left.
- **Emissary veins:** These veins connect the dural venous sinuses with the extracranial veins. Emissary veins lack valves, and blood may flow in either direction, though usually its flow is from the brain outward. Emissary veins vary in size and number. Children have a frontal emissary vein that may persist in some adults. The frontal emissary vein connects the superior sagittal sinus with the frontal sinus and nasal cavities. Parietal emissary veins may occur in pairs, passing through the parietal foramina in the calvaria and allowing flow between the superior sagittal sinus and the veins of the scalp. Occipital or posterior auricular veins connect with the sigmoid sinus via the mastoid emissary

This suggests that acupuncture, massage, and especially laser therapy may aid in improving visual processing and occipital lobe epilepsy by impacting brain behavior either indirectly through reflex connections or directly, as in photomedicine.

veins, which course through the mastoid foramina.

Clinical Relevance: The superior sagittal sinus may connect with the nose through an emissary vein, risking transmission of infection from the nose and "danger triangle of the face" (Yintang, GV 24.5) to the meninges and brain. The posterior auricular, occipital, and superficial temporal veins communicate to drain the region caudal to the ear. Blood from this extracranial plexus of veins transmits blood inside the cranium to the sigmoid sinus by means of the mastoid emissary veins. Because emissary veins lack valves, these vessels can transmit both blood and pus through the skull, allowing extracranial sources of infection to enter the intracranial cavity. This fact reinforces the need to follow clean needling practices and to avoid deep scalp insertion as well as traversing infected sites.

Lateral lacunae, also known as the lateral lakes of Trolard, exhibit variable positions but tend to occur near the vertex of the skull, between the coronal and lambdoid sutures. Arachnoid granulations (AG), i.e., herniations of the arachnoid membrane into the dural venous sinuses, allow egress of cerebrospinal fluid from the AG and into the venous system. Unusually large AG's in this region sometimes accompany signs of calvarial remodeling and superior sagittal sinus septation or duplication. Obstruction at the level of the bridging veins and venous lacunae can lead to brain swelling, as in benign intracranial hypertension.[12]

Patients with acute dural sinus thrombosis present commonly with worsening headache, nausea, and photophobia as intracranial venous pressure heightens.[13] The severe and sudden-onset "thunderclap" headache typifies the sinus thrombosis type of pain, taking only seconds to minutes to maximally intensify. Other causes of thunderclap headache include subarachnoid hemorrhage and cervical artery dissection. With sinus thrombosis, actions that raise intracranial pressure such as coughing and Valsalva maneuvers worsen headache.

Other patients with dural sinus thrombosis display signs and symptoms of stroke, including hemiparesis, dysfunction of one or more limbs, or dysphasia. In contrast to the more common "arterial" cause of stroke, sinus thrombosis may not confine its dysfunction to one side of the body.

About 40% of patients with sinus thrombosis have seizures, with the most common population including women around the time of giving birth. This condition is called "sinus thrombosis peripartum". In addition to seizure, patients may display altered mental status and/or weakness. Sinus thrombosis should be included in the differential diagnosis for elderly individuals with mental status change and depressed level of consciousness.

Risk factors for dural sinus thrombosis include coagulopathy, nephrotic syndrome, pregnancy, immediate post-pregnancy period (puerperium), oral contraceptives, meningitis, infection of the upper airways or ear, trauma to the venous sinuses, history of medical procedures to the head or neck, sickle cell anemia, dehydration, blood dyscrasia, chronic inflammatory disease, and homocystinuria.

Individuals with sufficient collateral flow might require only anticoagulant therapy but those who deteriorate and display imaging evidence of venous congestion might need thrombectomy and balloon-assisted thrombolysis in addition to anticoagulation. Laser therapy, acupuncture, and cranial manipulation (including the technique known as the "V-spread" would likely facilitate resolution of a dural sinus thrombosis. However, one should not delay proper diagnosis and treatment. Make the appropriate referral for emergency evaluation as the clinical condition dictates, then introduce physical medicine techniques after the patient receives indicated urgent interventions.

Indications and Potential Point Combinations

- **Tension headache:** GV 18, GV 20, GV 24.5 (Yintang), GV 14, temporalis trigger points, BL 10, GB 21, LI 4.
- **Vertigo, dizziness:** GV 18, GV 15, GB 8, GB 20, BL 10, LR 3, PC 6.
- **Visual processing disorders:** GV 18, GB 18, BL 9, LR 2, LR 3.
- **Neck pain or stiffness:** GV 18, GV 14, BL 10, GB 21, local trigger points.
- **Seizures, agitation:** GV 18, GV 20, BL 10, ST 36, LR 3.

GV 19

Hou Ding "Behind the Crown" "Behind the Vertex"

On the midline of the interparietal region, 1.5 cun rostral to GV 18, 1.5 cun caudal to GV 20. Located one-fourth the distance from GV 20 to GV 16. See Figure 14-52 to examine the relationships of the parietal bones to the occiput.

Cranial Suture

- **Sagittal suture:** This midline cranial suture serves as a rough external landmark for the underlying superior sagittal venous sinus. (See Figures 14-56 and 14-57.) At its caudal extent, however, the superior sagittal venous sinus often deviates to the right of the midline, draining into the right transverse sinus.[1]

Cranial sutures remain patent throughout brain growth; some or all may remain flexible, or unossified, throughout life. They act as active growth centers and interact with the dura by means of mechanical and biochemical reciprocity.[2]

Sutures of the vertebrate skull consist of two bone ends and intervening fibrous tissue, thereby constituting a fibrous joint.[3] More than merely bone articulations, the sutures exist as sites of primary osteogenesis, housing osteoprogenitor tissue that proliferates, differentiates, and functions at the bone margins.

Clinical Relevance: Cranial sutures accommodate changes in the size and conformation of the skull. Even in the adult, sutural mobility allows the cranium to expand and contract with intracranial pressure changes. Unossified sutures also modulate forces induced on the skull by temporal muscle contraction during mastication or teeth clenching.[4]

Maladaptive strain patterns in tissues that pull on cranial sutures can invoke pain and neurovascular dysfunction if the sensory nerves and vessels within the sutures become compressed. Nociceptors that supply the sutures arise from the meninges and relay intracranial and extracranial signals back and forth.[5,6] In other words, meningeal nociceptors send fibers through the suture to supply extracranial tissue, including periosteum on the skull surface. In the case of the sagittal suture, these nociceptors occur along the GV line. Sensory fibers along the lambdoid, coronal, and squamous sutures of the calvarium do the same.[7]

Bidirectional communication mediated by meningeal nociceptors explains why myofascial tension and inflammation in the temporalis, occipitofrontalis, and epicranial aponeurosis can trigger intracranial pain. Disturbances in the skin, connective tissue, and periosteum may also incite headache. Conversely, some patients with migraine complain that their skull feels "broken" or "crushed" when they undergo a severe episode.[8]

Dural neural supply of cranial sutures introduces additional nerve pathways by which neuromodulation fosters analgesia. Given that the caudal dura receives vagal afferents, extracranial meningeal fibers that exit through the sagittal suture at GV 19, GV 20, and possibly GV 18 at its caudal extent, ferry neuromodulation through vagal pathways. This helps why patients become relaxed with acupuncture at these sites. In contrast, acupuncture, massage, or acupressure at GV 21 would affect trigeminal fibers more strongly, though crosstalk between the trigeminal and vagus nerves still allows for vagal neuromodulation. GV 20, or "Hundred Convergences", receives both trigeminal and vagal input, accounting for its claim to fame as a strong relaxation point.

Connective Tissues

- **Skin:** This outer layer of the scalp consists of 5 layers: **S**kin, **C**onnective tissue (dense), **A**poneurosis, **L**oose connective tissue, and **P**ericranium. It ordinarily contains an abundant arterial supply as well as good venous and lymphatic drainage.
- **Dense connective tissue:** Comprises the thick and well-vascularized subcutaneous layer, rich with cutaneous nerves. Lacerations of the scalp bleed profusely as a consequence of abundant arterial anastomoses. These arteries fail to retract when cut because the dense connective tissue in the scalp maintains patency of arterial walls.
- **Galea aponeurotica (epicranial aponeurosis):** This strong, tendinous sheet, or aponeurosis, covers the calvarium and connects the occipitalis, superior auricular, and frontalis muscles; the collective term for this structure is the "epicranius muscle".
- **Loose connective tissue:** Resides deep to the galea aponeurotica, creating spaces capable of distending with fluid during infection or after trauma.
- **Pericranium:** This external periosteum of the calvarium exhibits continuity with the fibrous tissue inhabiting the cranial sutures.

Clinical Relevance: Scalp needling requires caution; the loose connective tissue layer constitutes the "danger area of the scalp", as infection from this layer may enter the cranium by way

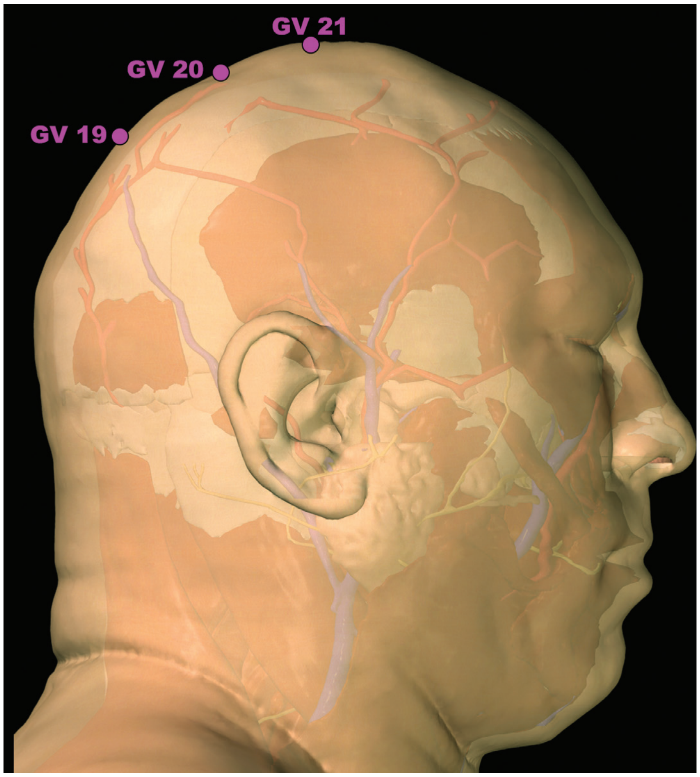

Figure 14-55. GV 19, "Behind the Crown", sits caudal to GV 20 while GV 21, is called "Before the Crown". Thus, the ancient acupuncturists considered GV 20 to identify the the crown or vertex of the head, even though GV 20 does not sit at the highest point of the skull.

Figure 14-56. GV 19, GV 20, and GV 21 overlie the sagittal cranial suture as well as the superior sagittal sinus. Developmental, mechanical, and neural connections between the dura, cranial sutures, and dural venous sinuses heighten the likelihood that acupuncture and related techniques will influence cerebral venous drainage and CSF flow through neuromodulation.

of emissary veins that course through calvarial foramina.

Tissue at GV 19 can become tender to palpation with occipitofrontalis tension, as in tension headache, as well as migraine and chronic neck pain. Trigger point pathology in other muscles of the head and neck also refer pain to the back of the head. These include the trapezius, sternocleidomastoid, semispinalis, splenius, suboccipital group, occipitalis, digastric and temporalis.

Nerves

- **Third ("Least") occipital nerve, or TON (C3):** Innervates the skin of the medial occipital and cervical regions. This dorsal ramus of the C3 spinal nerve separates into a complex system of branches after emerging from the articular pillar of the C3 vertebra. It divides into medial and lateral branches, with the medial further separating into deep and superficial divisions.[9]
- **Greater occipital nerve, or GON (C2, (C3)):** Supplies cutaneous sensation to the posterior scalp. Arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[10] As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.

Clinical Relevance: Neuroanatomically, the upper cervical nerves supply sensation to the somatic structures, sending occipital nerves along the back of the head.

These nerves crosstalk with the vagus that then supplies the meninges in the posterior cranial fossa. The hypoglossal nerve provides meningeal branches to this region, too, joining a branch from the ventral ramus of C1. The facial nerve supplies the occipitofrontalis muscle. The impact of stimulating points on the head in order to mitigate head pain becomes clear when considering the extensive communication network between cranial nerves V, VII, X, and XII, along with interactions between these nerves and the upper cervical spinal cord segments.

Delineating the interrelationships of cranial, cervical, and autonomic nerves responsible for head pain and cranial dysfunction allows for a fuller understanding of the beneficial influence of neuromodulation on specific forms of headache. Isolating, to the degree possible, which components of the myofascial, cranial nerves, autonomic nervous system, and spinal cord segments gives one the ability to target acupuncture, massage, and laser therapy to the appropriate instigator(s). Trigeminal autonomic cephalalgias (TACs) comprise cluster headache, paroxysmal hemicranias, and short-lasting unilateral neuralgiform headache with conjunctival injection and tearing (SUNCT), short-lasting unilateral neuralgiform headache attaches with cranial autonomic features (SUNA), and hemicrania continuua.

Involvement of the trigeminovascular system is a main feature of TACs.[11] That is, in TACs, nociceptive afferent input from cranial vessels and the dura mater travels through the ophthalmic division of the trigeminal nerve to the trigeminocervical complex. From here, nociceptive impulses travel to the thalamus and cortex and result in pain perception. Stimulation of meningeal afferent nerves by dint of acupuncture at GV 19, GV 20, and GV 21 neuromodulates the trigeminovascular system, activating reflexes in the trigeminocervical complex that synapse in the superior salivatory nucleus housed within the pons. From the superior salivatory nucleus, cranial parasympathetic fibers course with either 1) the greater petrosal nerve after synapsing in the sphenopalatine ganglion, or 2) the facial nerve en route to the lacrimal gland. Endogenous neuromodulation of the trigeminocervical complex and superior salivary nucleus may result from activation of the periaqueductal grey, locus coeruleus, nucleus raphe magnus, and hypothalamus.

Overstimulation of the trigeminocervical complex also occurs in cases of temporomandibular dysfunction and cervical spine dysfunction.[12]

Occipital nerve stimulation treats not only occipital neuralgia but also other primary headache conditions as well, including migraine and cluster headache.[13] Acupuncture and related physical medicine techniques have the advantage over nerve ablation and neurostimulator procedures by being less invasive and avoiding the painful and cost of implantation. In addition, they address myofascial sources of pain rather than worsening them by traumatizing tissues. While medications may provide some pain relief, neuroanatomic acupuncture treats the source whereas drugs either may not work or cause insufferable or otherwise adverse side effects.

Occipital nerve stimulation activates pain modulation pathways in the spinal cord and brainstem. Mechanoreceptor stimulation of the occipital nerves (the greater, lesser, and least or third) reaches the C2 and C3 spinal cord segments and trigeminocervical complex. From here, information ascends to the rostral ventromedial medulla, dorsolateral pontomesencephalic tegmentum, periaqueductal gray, thalamus, and cortex. Endogenous analgesic pathways from brainstem to spinal cord modulate pain processing through inhibitory anti-nociceptive projections to the cervical dorsal horn.

Postcraniotomy pain and headache can be severe and disabling due to the abundant supply of sensory fibers in the cranial dura mater.[14] Nerve supply to the dura of the head has been a matter of some debate. Some claim that the trigeminal nerve simply supplies supratentorial structures while the vagus nerve supplies infratentorial regions, but further investigation suggests that dural innervation has far more complexity.

Kemp et al.[15] outlined the innervation pattern as follows: the anterior and posterior ethmoidal nerves supply the anterior third of the falx cerebri, fibers from the ophthalmic division of the trigeminal nerve supply the mid-falx cerebri, and the nervus tentoria of Arnold (a branch of ophthalmic division of the trigeminal) supplies the posterior third of the falx cerebri. Sympathetic fibers from the superior cervical ganglion innervate the superior sagittal sinus as well as other regions of the supratentorial dura mater.

Fibers from the ophthalmic division of the trigeminal nerve reach the tentorium cerebelli. The middle cranial fossa is supplied by the mandibular division of the trigeminal nerve and the nervus meningeus medius from the maxillary division of the trigeminal nerve.

The posterior fossa receives innervation from the several sources, including the facial, glossopharyngeal, and vagus nerves. In addition, branches of the sympathetic trunk (coursing through the superior cervical ganglion) innervate the posterior cranial fossa as do meningeal branches of the upper three cervical spinal nerves. Recurrent branches of the vagus nerves supply the inferior wall of the transverse sinus and falx cerebri. The hypoglossal may contribute fibers to the dura in the posterior fossa as well.

As far back as 1941, neurosurgeons found possible correspondence between irritation of sites along the dura and specific areas of head pain.[16] It behooves clinicians to closely examine and palpate patients' calvaria for treatment and prevention of head pain by considering the neuroanatomic pathways involved. Accurate neuroanatomic localization fosters accurate neuromodulation.

Vessels

- **Anastomosis between right and left occipital arteries:** Arising from the external carotid artery, each occipital artery courses along a groove in the base of the skull, and ends in the posterior portion of the scalp.
- **Anastomosis between right and left occipital veins:** The occipital veins typically drain into the suboccipital venous plexus, which drains into the vertebral vein and the deep cervical vein, but occasionally it may drain into the internal jugular vein.
- **Emissary veins:** These veins connect the dural venous sinuses with the extracranial veins. Emissary veins lack valves, and blood may flow in either direction, though usually its flow is from the brain outward. Emissary veins vary in size and number. Children have a frontal emissary vein that may persist in some adults. The frontal emissary vein connects the superior sagittal sinus with the frontal sinus and nasal cavities. Parietal emissary veins may occur in pairs, passing through the parietal foramina in the calvaria and allowing flow between the superior sagittal sinus and the veins of the scalp. Occipital or posterior auricular veins connect with the sigmoid sinus via the mastoid emissary veins, which course through the mastoid foramina.
- **Superior sagittal (longitudinal) sinus:** The superior sagittal sinus forms along the convex surface of the falx cerebri and follows the GV line along its entire length. Triangular in shape, the sinus widens at its caudal extent in the vicinity of GV 19, GV 20, and GV 21. See Figure 14-48 to examine the superior sagittal sinus and its connections with the confluence of sinuses and the transverse sinuses.

Venous blood draining from the brain flows through superior cerebral veins, into the dural sinuses, and finally into the internal jugular vein. Venous lacunae communicate with the superior sagittal sinus on either side; their sizes vary and include a small frontal, a large parietal, and an intermediate-size occipital lacuna. Veins from the diploe and dura mater, as well as from the pericranium, empty into the superior sagittal sinus as well after passing through parietal foramina.

Clinical Relevance: Extracranial nerve stimulation by means of acupuncture and related techniques may affect the rate or amount of blood flow in the sagittal suture by neuromodulating local autonomic fibers. Neuromodulation may also influence cerebrospinal fluid (CSF) flow. CSF drains into the superior sagittal sinus through arachnoid granulations, otherwise known as arachnoid villi.

In several regions of the skull, the superior sagittal sinus connects with the extracranial veins through emissary veins. This risks transmission of infection from scalp or face to meninges and brain. At or near GV 19, the parietal emissary vein links the superior sagittal sinus with the occipital vein.[17] Within the cranial bones, parietal emissary veins interface with the diploic veins as well. An example of the diploic vessels appears in Figure 14-57. This extensive connectivity of intracranial and extracranial veins by means of emissary veins supports brain cooling.

Lateral lacunae, also known as the lateral lakes of Trolard, occur at variable positions but tend to manifest near the vertex of the skull between the coronal and lambdoid sutures, coinciding with area described by GV 19 through GV 21.

Arachnoid granulations (AG), i.e., herniations of the arachnoid membrane into the dural venous sinuses, allow egress of cerebrospinal fluid from the AG and into the venous system. Unusually large AG's in this region sometimes signify calvarial remodeling and superior sagittal sinus septation or duplication. Obstruction at the level of the bridging veins and venous lacunae may promote brain swelling, as in benign intracranial hypertension.[18]

Figure 14-57. This cross-section deep to GV 19 exposes the relationship between the extracranial tissue at the point to the sagittal suture, diploic vessels, lateral lacunae, and the superior sagittal sinus. When one considers the neural links between meningeal sensory neurons, sutural neurovascular elements, and extracranial collaterals of meningeal nerves, the potential for neuromodulation of intracranial blood and CSF flow becomes clear.

Patients with acute dural sinus thrombosis may complain of headache that worsens as intracranial venous pressure increases.[19] The severe and sudden-onset “thunderclap” headache typifies the sinus thrombosis type of pain, taking only seconds to minutes to maximally intensify. Additional causes of thunderclap headache include subarachnoid hemorrhage and cervical artery dissection. With sinus thrombosis, actions that raise intracranial pressure such as coughing and Valsalva maneuvers worsen headache. Some patients report visual disturbances and exhibit papilledema because of elevated intracranial pressure.[20]

Other patients with dural sinus thrombosis display signs and symptoms of stroke, including hemiparesis, dysfunction of one or more limbs, or dysphasia. In contrast to the more common “arterial” cause of stroke, paresis or paralysis from sinus thrombosis may extend beyond one side of the body.

About 40% of patients with sinus thrombosis have seizures, with the most common population including women around the time of giving birth. This condition is called “sinus thrombosis peripartum”. In addition to seizure, patients may display altered mental status and/or weakness. Sinus thrombosis should be included in the differential diagnosis for elderly individuals with mental status change and depressed level of consciousness.

Risk factors for dural sinus thrombosis include coagulopathy, nephrotic syndrome, pregnancy, immediate post-pregnancy period (puerperium), oral contraceptives, meningitis, infection of the upper airways or ear, trauma to the venous sinuses, history of medical procedures to the head or neck, sickle cell anemia, dehydration, blood dyscrasia, chronic inflammatory disease, and homocystinuria.

Individuals with sufficient collateral flow might require only anticoagulant therapy but those who deteriorate and display imaging evidence of venous congestion might need thrombectomy and balloon-assisted thrombolysis in addition to anticoagulation. Laser therapy, acupuncture, and cranial manipulation (including the technique known as the “V-spread” would likely facilitate resolution of a dural sinus thrombosis. However, one should not delay proper diagnosis and treatment. Make the appropriate referral for emergency evaluation as the clinical condition dictates, then introduce physical medicine techniques after the patient receives indicated urgent interventions.

Indications and Potential Point Combinations

- **Tension headache radiating to the vertex:** GV 19, GV 20, GV 21, BL 7, BL 8, GB 14, temporalis trigger points, BL 10, GB 21, LI 4. Acupressure in a “V spread” fashion along the cranial sutures.
- **Neck pain or stiffness:** GV 19, GV 14, BL 10, GB 21, local trigger points.

- **Stress headache:** Acupressure, osteopathic cranial manipulation focused on GV 19, GV 20, and GV 21, as well as GV 24.5 and GV 14. Include other regions as the patient's presentation and myofascial palpation findings suggest.

GV 20

Bai Hui "100 Convergences"

Draw an imaginary line from the lobe of the ear to its highest point on the helix. Where the continuation of this line meets the midline, you will find GV 20, as shown in Figure 14-58. Note that GV 20 does not designate the highest point of the cranium.

In a depression 5 cun behind the anterior hairline and 7 cun anterior to the posterior hairline. Also located 8 cun posterior to the glabella and 6 cun superior to the external occipital protuberance.

Cranial Suture

- **Sagittal suture at the level of right and left parietal foramina:** This midline cranial suture serves as a rough external landmark for the underlying superior sagittal sinus. At its caudal extent, the superior sagittal sinus often deviates to the right, tending to drain more frequently into the right transverse sinus.[1] The parietal foramina, which may be paired, occur near the sagittal suture and transmit emissary veins, connecting the scalp to the superior sagittal sinus.

Clinical Relevance: Cranial sutures allow for changes in the size and conformation of the skull. When maintained in the adult, sutural mobility accommodates cranial expansion and contraction with intracranial pressure changes. In addition, flexible sutures modulate strain placed on the skull by calvarial muscle contraction during mastication.

Myofascial dysfunction that pulls on cranial sutures can invoke pain and neurovascular dysfunction by compressing nerves and vessels. Sutural compaction activates extracranial nociceptors of meningeal origin that supply the sutures. These fibers relay signals back and forth across the calvarium.[29,30] Sensory fibers that innervate the lambdoid, coronal, and squamous sutures of the calvarium do the same.[31]

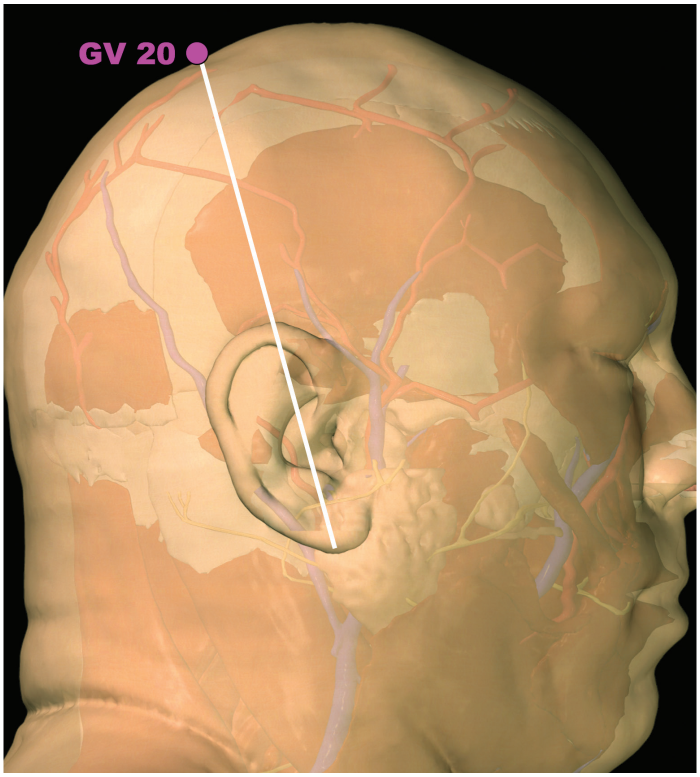

Figure 14-58. Locate GV 20 by connecting, at the midline, lines drawn from earlobe to the highest point on the helix. Here, the white line illustrates the angle from earlobe to GV 20.

Bidirectional communication mediated by meningeal nociceptors helps to explain how myofascial tension and inflammation in the temporalis, occipitofrontalis, and epicranial aponeurosis incites intracranial pain. Disturbances in the skin, connective tissue, and periosteum may in turn also instigate headache. Conversely, some patients with migraine, considered a source of intracranial pain, complain that their skull hurts, and not their "brain".[32]

The fact that nociceptors from the dura innervate cranial sutures introduces opportunities for neuromodulation, either directly along the GV line as in the case of the sagittal suture, or indirectly through cervical and trigeminal nerves that cross talk with dural fibers. GV 20, called "Hundred Convergences", interacts with both trigeminal and vagal extracranial afferents, accounting for its notoriety as a strong point that calms patients. Note the number of nerves that reach for the point as shown in Figure 14-59B.

Connective Tissues

Connective Tissues of the **"SCALP"** consists of 5 layers, i.e., **S**kin, **C**onnective tissue (dense), **A**poneurosis, **L**oose connective tissue, and **P**ericranium

- **Skin:** Contains an abundant arterial supply as well as good venous and lymphatic drainage capacity.
- **Dense connective tissue:** Comprises the thick and well-vascularized subcutaneous layer, richly supplied with cutaneous nerves.
- **Galea aponeurotica (epicranial aponeurosis):** This strong, tendinous sheet, or aponeurosis, covers the calvaria and connects the occipitalis, superior auricular, and frontalis muscles; the collective term for this structure is the "epicranius muscle".
- **Loose connective tissue:** Resides beneath the galea aponeurotica, affording many potential spaces that may distend with fluid following infection or trauma.
- **Pericranium:** This is the external periosteum of the calvaria, continuous with the fibrous tissue in the cranial sutures.

Clinical Relevance: Scalp needling requires caution; the loose connective tissue layer constitutes the "danger area of the scalp", as infection from this layer may enter the cranium by way of emissary veins that course through calvarial foramina.

Lacerations of the scalp may bleed profusely as a consequence of the abundance of arterial anastomoses in the scalp. These arteries fail to retract when cut because the dense connective tissue in the scalp maintains patency of the artery walls.

Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as GV 20, as well as deactivating trigger points in the frontalis (e.g., GB 14) and the occipitalis (e.g., BL 9) muscles. Lateral pull from the temporalis fascia accentuates tension in the epicranial aponeurosis and predisposes patients to headache syndromes. It may also irritate the lesser occipital nerve, which appears in Figure 14-59B.

Nerves

- **Third ("Least") occipital nerve, or TON (C3):** Innervates the skin of the medial occipital and cervical regions. This dorsal ramus of the C3 spinal nerve separates into a complex system of branches after emerging from the articular pillar of the C3 vertebra. It divides into medial and lateral branches, with the medial further separating into deep and superficial divisions.[33]
- **Lesser occipital nerve, or LON (C2, C3):** Supplies sensation to the scalp on the lateral aspect of the head, caudal to the auricle. The LON also innervates the skin of the caudal or convex portion of the auricle and communicates with the mastoid branch of the greater auricular nerve. May arise from the GON.
- **Greater occipital nerve, or GON (C2, (C3)):** Supplies cutaneous sensation to the posterior scalp. Arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[34] As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.
- **Spinal nerves C2 and C3:** Innervate the scalp caudal to the auricles; the dorsal roots of C2 and C3 innervate the caudal cranial fossa.
- **Auriculotemporal nerve (CN V_3):** Provides sensory innervation to the skin anterior to the ear, along the posterior temporal region, the tragus, and part of the helix of the auricle. Provides sensation to the roof of the external acoustic meatus and the upper portion of the tympanic membrane.
- **Supraorbital nerve (CN V_1):** The supraorbital nerve is a continuation of the frontal nerve, innervates the mucous membrane of the frontal sinus and the upper eyelid conjunctiva, and provides sensation to the forehead skin and vertex.

Clinical Relevance: GV 20 receives innervation from both trigeminal and cervical spinal nerve extracranial and intracranial sources. That is, the sagittal suture (related to GV 19, GV 20, and GV 21) receives nerve fibers from superficial trigeminal and cervical nerves as well as intracranial meningeal afferent fibers. Furthermore, the three most cranial cervical spinal nerve roots communicate with the trigeminal nerve system by converging onto neurons in the spinal nucleus of the trigeminal nerve.[35] This explains the widespread sensory, motor, and autonomic phenomena that arise in various headache states, including migraine and occipital neuralgia.

Delineating the interrelationships of cranial, cervical, and autonomic nerves responsible for head pain and cranial dysfunction allows for a fuller understanding of the beneficial influence of neuromodulation on specific forms of headache. Isolating, to the degree possible, which components of the myofascial, cranial nerves, autonomic nervous system, and spinal cord segments gives one the ability to target acupuncture, massage, and laser therapy to the appropriate instigator(s). Trigeminal autonomic cephalalgias (TACs) comprise cluster headache, paroxysmal hemicranias, and short-lasting unilateral neuralgiform headache with conjunctival injection and tearing (SUNCT), short-lasting unilateral neuralgiform headache attaches with cranial autonomic features (SUNA), and hemicrania continuua.

Involvement of the trigeminovascular system is a main feature of TACs.[36] That is, in TACs, nociceptive afferent input from cranial vessels and the dura mater travels through the ophthalmic division of the trigeminal nerve to the trigeminocervical complex. From here, nociceptive impulses travel to the thalamus and cortex and result in pain perception. Stimulation of meningeal afferent nerves by dint of acupuncture at GV 19, GV 20, and GV 21 neuromodulates the trigeminovascular system, activating reflexes in the trigeminocervical complex that synapse in the superior salivatory nucleus housed within the pons. From the superior salivatory nucleus, cranial parasympathetic fibers course with both 1) the greater petrosal nerve after synapsing in the sphenopalatine ganglion, and 2) the facial nerve en route to the lacrimal gland. Endogenous neuromodulation of the trigeminocervical complex and superior salivary nucleus may result from activation of the periaqueductal grey, locus coeruleus, nucleus raphe magnus, and hypothalamus.

Overstimulation of the trigeminocervical complex can occur in cases of temporomandibular dysfunction and cervical spine dysfunction.[37]

Occipital nerve stimulation treats not only occipital neuralgia but also other primary headache conditions, including migraine and cluster headache.[38] Acupuncture and related physical medicine techniques have the advantage over nerve ablation and neurostimulator procedures by being less invasive and avoiding the painful and cost of implantation. In addition, they address myofascial sources of pain rather than worsening them by traumatizing tissues. While medications may provide some pain relief, neuroanatomic acupuncture treats the source whereas drugs either may not work or cause insufferable or otherwise adverse side effects.

Occipital nerve stimulation activates endogenous pain modulation pathways in the spinal cord and brainstem. Mechanoreceptor stimulation of the occipital nerves (i.e., the greater, lesser, and least or third) reaches both spinal cord in the C2 and C3 and brainstem at the trigeminocervical complex. Neural signals then ascend to the rostral ventromedial medulla, dorsolateral pontomesencephalic tegmentum, periaqueductal gray, thalamus, and cortex. Endogenous analgesic pathways from brainstem to spinal cord modulate pain processing through inhibitory anti-nociceptive projections to the cervical dorsal horn.

Post-craniotomy pain and headache can be severe and disabling due to the abundant supply of sensory fibers in the cranial dura mater.[39] Nerve supply to the dura of the head has been a matter of some debate. Some claim that dural sensation simply takes the form of trigeminal supply of supratentorial structures and vagal supply of infratentorial regions, but further investigation suggests far more complexity, as follows.[40] The anterior and posterior ethmoidal nerves supply the anterior third of the falx cerebri, fibers from the ophthalmic division of the trigeminal nerve supply the mid-falx cerebri, and the nervus tentoria of Arnold (a branch of ophthalmic division of the trigeminal) supplies the posterior third of the falx cerebri. Sympathetic fibers from the superior cervical ganglion innervate the superior sagittal sinus as well as other regions of the supratentorial dura mater.

Fibers from the ophthalmic division of the trigeminal nerve reach the tentorium cerebelli. The middle cranial fossa is supplied by the mandibular division of the trigeminal nerve and the nervus meningeus medius from the maxillary division of the trigeminal nerve.

The posterior fossa receives innervation from the several sources, including the facial, glossopharyngeal, and vagus nerves. In addition, branches of the sympathetic trunk (coursing through the superior cervical ganglion) innervate the posterior cranial fossa as do meningeal branches of the upper three cervical spinal nerves. Recurrent branches of the vagus nerves supply the inferior wall of the transverse sinus and falx cerebri. The hypoglossal may contribute fibers to the dura in the posterior fossa as well.

As far back as 1941, neurosurgeons found possible correspondence between irritation of sites along the dura and specific areas of head pain.[41] It behooves clinicians to closely examine and palpate patients' calvaria for treatment and prevention of head pain by considering the neuroanatomic pathways involved. Accurate neuroanatomic localization fosters accurate neuromodulation.

The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[42] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The

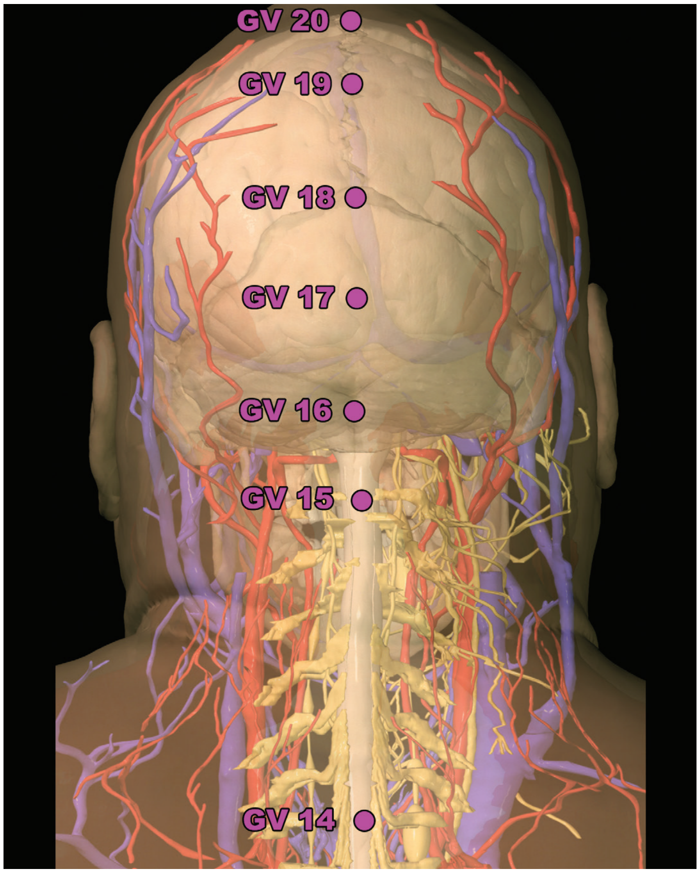

Figure 14-59A. This caudal view of the head and neck exposes the neurovascular supply of the brain in all its splendor, with GV 20 at the crown.

Figure 14-59B. The name, "Hundred Convergences" for GV 20 describes the meeting of many channels, i.e. neurovascular pathways. As shown here, occipital nerves from C2 and C3 converge with trigeminal nerve branches from each of the three divisions of the trigeminal nerve. Upper cervical spinal nerves communicate with the vagus nerve, as do trigeminal pathways. This explains the application of GV 20 for vagal-responsive conditions, including seizures, anxiety, depression, and stress-related malfunctions such as erectile dysfunction.

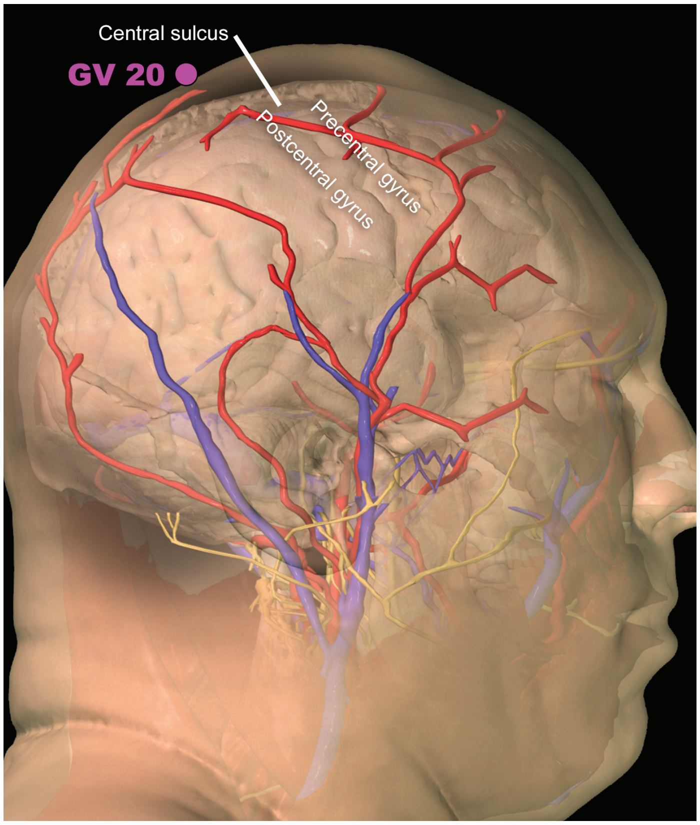

Figure 14-59C. Knowing where the central sulcus resides in relation to GV 20 could prove beneficial for the treatment of brain disorders with laser therapy.[62]

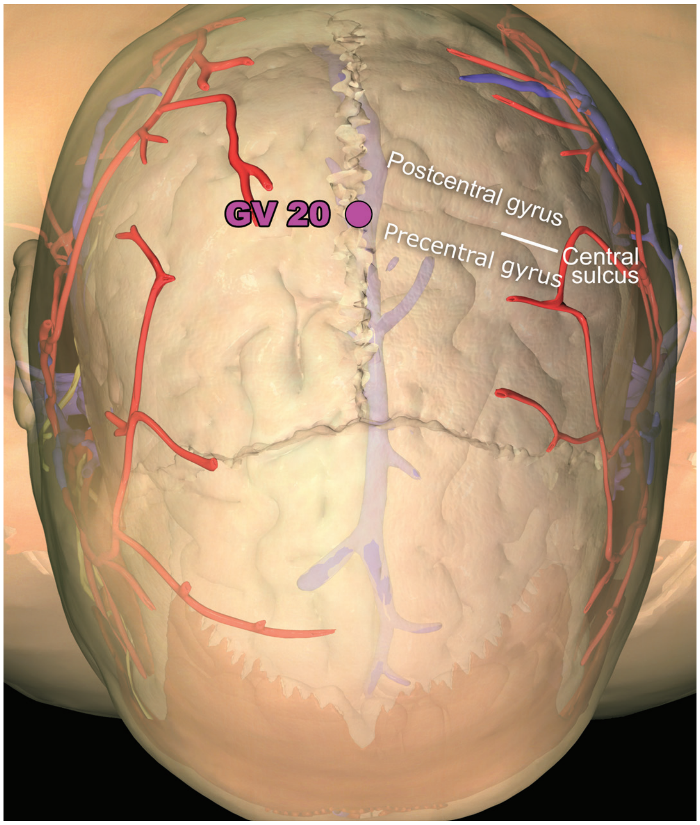

Figure 14-59D. This view from the vertex depicts the relationships of GV 20 to the central sulcus, a landmark that separates the parietal lobe from the frontal lobe. The precentral gyrus contains the primary motor cortex while the postcentral gyrus houses the somatosensory cortex. Brain anatomy underlying acupuncture points becomes especially important when introducing laser therapy as a direct means of brain neuromodulation.

numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can occur at GB points on the side of the head and elsewhere along the neurovascular course. Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[43] From a trigger point perspective, although muscles are largely absent from the vertex, dysfunction in the sternocleidomastoid (sternal head) and the splenius capitis sometimes refer pain to the top of the head, surrounding GV 20. As such, patients presenting with vertex pain may be harboring trigger points in the cervical musculature.

The auriculotemporal nerve also impacts balance. Stomatognathic disorders, i.e., problems with mouth, teeth, mandible, pharynx, and other structures associated with mastication, speech, and deglutition, negatively impact posture, balance, and gait. GV 20 often serves as an ancillary point for balance problems along with various GB and other GV points.

Muscle reflex responses controlling balance and equilibrium depend on input into the reticular formation from several sources. Afferents arise from trigeminal, auditory, proprioceptive, visual, vestibular, cutaneous, and autonomic pathways. The extensive reticular formation in the brainstem integrates this information, couples it with input from the brain, and forwards it to brainstem nuclei that oversee sensation, motor activity, and autonomic function. Afferent information makes its way to the nucleus raphe magnus in the reticular formation via the spinal tract of V. These inputs can influence reflex arcs and motor responses from the face and cranium.

Painful dentition and abnormal TMJ mechanics send nociceptive input that may sensitize neural pathways related to auriculotemporal nerve pathways. These facilitated reflexes between the reticulospinal and nucleus raphe magnus tracts may lead to involuntary rhythmic tremors, gait disturbances, and postural imbalance. In this way, afferent impulses transmitted through trigeminal nerve circuitry have the capacity to change tonic or "resting" activity within the reticular formation. Altered tonic activity impacts the nature of eye movements, posture, respiration, arousal, sleep, pain, vasomotor tone, cardiac output, feeding, and homeostasis in general.

Taking all of these reflexes into account, trigeminal nerve input ferried through the auriculotemporal nerve works alongside sensory, oculomotor, and vestibular afferents to manage a variety of highly coordinated activities.

Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel and includes the midline GV channel) to the vertex.[44] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes.

Similar syndromes to SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, and other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (i.e., at the supraorbital notch). Dry needling of BL 2, BL 7, GV 21, GV 20, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

Vessels

- **Anastomosis between right and left parietal branches of the superficial temporal arteries:** The superficial temporal arteries begin as terminal branches of the external carotid arteries and ascend anterior to the ear, course over the temporal region, and terminate in the scalp. They bring blood circulation to the facial muscles and the skin of the frontal and temporal regions of the scalp.
- **Anastomosis between right and left parietal tributaries of the superficial temporal veins:** The superficial temporal veins originate from the widespread plexus of veins coursing on the side of the scalp and along the zygomatic arch. The parietal tributaries drain the parietal region and unite with the frontal branches anterior to the auricle. They then cross the temporal root of the zygoma and travel from the temporal region to the parotid gland. They then join the maxillary vein posterior to the neck of the mandible and become the retromandibular vein.
- **Anastomosis between right and left supraorbital arteries:** The supraorbital arteries arise from the ophthalmic arteries and pass through the supraorbital foramina to supply the forehead and scalp.
- **Anastomosis between right and left supraorbital veins:** The supraorbital veins drain the rostral superficial scalp through the supraorbital and supratrochlear veins, which unite at the medial angle of the eye to form the angular vein. The angular vein becomes the facial vein at the inferior orbital margin.
- **Emissary veins:** These veins connect the dural venous sinuses with the extracranial veins. Emissary veins lack valves, and blood may flow in either direction, though usually its flow is from the brain outward. Emissary veins vary in size and number. Children have a frontal emissary vein that may persist in some adults. The frontal emissary vein connects the superior sagittal sinus with the frontal sinus and nasal cavities. Parietal emissary veins may occur in pairs, passing through the parietal foramina in the calvaria and allowing flow between the superior sagittal sinus and the veins of the scalp. Occipital or posterior auricular veins connect with the sigmoid sinus via the mastoid emissary veins, which course through the mastoid foramina.

Clinical Relevance: The superior sagittal sinus closely follows the course of the GV line as indicated in Figure 14-59A. Embryologically, the superior sagittal sinus begins as two parallel structures that merge. The lateral lacunae that lie on either side of the sinus may represent remnants of the early double plexus. Their locations vary. The lacunae function as autoregulators of blood flow as they control venous outflow resistance. Pathology within the lateral lacunae of the sagittal sinus compromises this draining activity. This may lead to brain swelling by reducing venous outflow. Lateral lacunae stenosis, which occurs in young women with endocrine disorders, can lead to benign intracranial hypertension.[45]

Arachnoid villi (or arachnoid granulations) are protrusions of the arachnoid layer of the meninges, through the dura mater, and into the venous sinuses of the brain. The arachnoid villi provide an exit route for cerebrospinal fluid (CSF) from the brain and into the venous system. The largest arachnoid villi occur along the superior sagittal venous sinus.

Under normal circumstances, CSF draining from arachnoid villi keeps intracranial pressure from building.

Pain-sensitive fibers from the ophthalmic division of the trigeminal nerve supply sensation to the venous sinuses. These sinuses include the superior sagittal sinus, the meningeal arteries, and much of the supratentorial dura. Trigeminal fibers also supply the circle of Willis and other cerebral arteries as they join fibers from the sympathetic plexus.

Trigeminal nerve irritation is central in the pathophysiology of head and facial pain.[46]

Supraorbital vessels anastomose with superficial temporalis vasculature. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and irritating nerves.

Indications and Potential Point Combinations

- **Mental and emotional conditions, insomnia, agitation:** GV 20, HT 3, HT 7, PC 6, ST 36.
- **Headache:** GV 20, GV 24.5, BL 10, GV 21, local trigger points.
- **Dizziness:** GV 20, GV 14, GB 20, GB 34, BL 10, temporalis trigger points, LR 3.
- **Hemiplegia:** GV 20, BL 7, TH 20, ST 36, appropriate points according to neurologic dysfunction.
- **Seizures:** GV 20, BL 7, BL 8, BL 10, HT 7, ST 36, LR 3, LI 4.
- **Prolapse of uterus, rectum:** GV 20, GV 1, GV 2, GV 3, BL 35.
- **Hemorrhoids:** GV 20, GV 1, GV 2, BL 35.
- **Urinary incontinence:** GV 20, BL 31-34, KI 3, CV 3, SP 6.

Evidence-Based Applications

- A Chinese trial reported that acupuncture at GV 20, ST 40, GB 20, LU 7, and GV 14 benefited patients with **vertebrobasilar ischemic vertigo.**[2]

- Acupuncture at GV 20 increases **cerebral blood flow.**[47]
- Acupuncture at GV 20 markedly **decreases arterial stiffness** and wave reflection as indicated by the augmentation index, likely through neurovascular modulators.[48]
- **Autonomic neuromodulation** by means of SiShenCong (GV 20 plus four points 1 cun away from GV 20 in cranial, caudal, and bilateral directions) enhanced cardiac vagal and suppressed sympathetic activities in humans.[3]
- Acupuncture at GV 4, GV 9, GV 10, GV 11, GV 14, and GV 20 helped relieve symptoms related to **narcotic drug withdrawal.**[4]
- Electroacupuncture at GV 20, Sishencong, Li 4, PC 6, LR 3, and SP 6 along with psychotherapy improved the cognitive function of patients with **internet addiction.**[49]
- Electroacupuncture at GV 20, GV 24.5, and either (GB 34 + SP 6), (PC 6 + SP 6), or (KI 3 + SP 6) – depending on the type of **depression** – treated depression as effectively as tricyclic antidepressant medication.[5]
- Laser acupuncture significantly outperformed sham laser for the treatment of **mild to moderate depression** with the following points: LR 8, LR 14, CV 14, CV 15, HT 7, SP 6, LI 4, and GV 20.[6]
- A Chinese study reported benefits of acupuncture at LI 4, LR 3, GV 20, and Yintang along with ear acupuncture for patients with **depressive neurosis.**[7]
- Teleacupuncture at GV 20 reduced mean heart rate and increased total heart rate variability significantly in patients with **depression.**[50]
- Electroacupuncture at GV 20, Sishencong, GV 24, and GB 20 produced more significant changes in earthquake-caused **posttraumatic stress disorder** than paroxetine.[51]
- Acupuncture at GV 20 and Extra point 6 significantly reduced **anxiety** related to dental treatment.[52]
- Stimulation of GV 20 in a chronic **cerebral hypoperfusion and cerebral infarct** rat model for 20 minutes a day for 3 days weekly over 4 weeks increased dopamine levels in the brain and reduced brain atrophy after cerebral infarct. This suggested that GV 20 stimulation offered **neuroprotection** after injury.[8]
- Electroacupuncture at GV 20 and GB 7 improved cerebral motor plasticity after **ischemic stroke,** possibly by activating motor regions such as the insula, putamen, and cerebellum.[53]
- Electroacupuncture at GV 20 and Yintang (GV 24.5) caused changes in the frontal lobe, cingulate gyrus, and cerebellum, perhaps linking these sites to benefits of treating these points, especially for patients with **psychiatric disorders.**[54]
- EA at GV 2, GV 14, GV 20, GV 24.5, prevented tissue shrinkage of the dorsal hippocampus, basolateral nucleus of the amygdala, substantia nigra, and perirhinal cortex. EA at ST 36 and SP 6 prevented tissue shrinkage in all of the aforementioned regions except for the dorsal hippocampus. EA to GV 2 + GV 14 + GV 20 + GV 24.5 or ST 36 + SP 6 reduced the cognitive deficits in pilocarpine-epileptic rats. Administration of p-chlorophenylalanine, a compound that depletes serotonin, negated the behavioral and some of the histologic changes due to EA. This suggests that the functional recovery exhibited by the rats may have been influenced through serotonergic pathways affected by acupuncture and subsequent **neuroprotective** benefits.[9]
- A Chinese study compared the effects of needling GV 20, GV 26, and HT 7 on positron emission computerized tomography (PET) and single photo emission computerized tomography (SPECT) scans.[10] Brain sites activated by needling GV 20 might increase patients' activity in **temporal and spatial orientation and certain cognitive activities.** This was based on findings associated glucose metabolism or blood flow in the frontal, temporal, and parietal lobes.
- Acupuncture at LR 3, SP 6, ST 36, CV 12, LI 4, PC 6, GB 20, GB 14, Taiyang, and GV 20 provided greater effectiveness in prophylaxis of **migraine** compared to flunarizine.[11]
- Acupuncture at LR 3, SP 6, LI 4, GB 20, GV 20, and Taiyang outper formed transcutaneous electrical nerve stimulation and laser therapy in reducing the frequency of **migraine,** although all three treatments were effective.[12]
- Acupuncture at GV 20, GB 20, GB 8, LR 2, PC 6, SP 6, and ashi points plus a Chinese herbal decoction reduced and shortened the duration of **vascular headache** according to a Chinese report.[13]
- Acupressure at GV 20, GB 20, BL 2, TH 21, GB 5, and other sites more effectively benefited patients with **chronic headache** than did the administration of muscle relaxant medication for the same duration. The effect of trigger point acupressure lasted for six months.[55]
- Electroacupuncture at LI 4, LU 7, GV 14, GV 20, the thoracolumbar midline point San Tai and the lumbosacral midline point Baihui (veterinary) demonstrated a reduction of minimum alveolar concentration (MAC) of isoflurane by 16.7% in dogs. **Acupuncture-assisted anesthesia** thus potentiated the anesthetic effects of volatile anesthetic agents.[14]
- Electroacupuncture at GV 20, Yintang, auricular Shenmen, Sishencong, and Anmian provided some benefit over placebo acupuncture for patients with **insomnia.**[56]
- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[15]
- Three out of three RCTs supported effectiveness of acupuncture for the treatment of **temporomandibular disorders,** prompting the following treatment recommendation: ST 6, ST 7, SI 18, GV 20, GB 20, BL 10, and LI 4.16
- Electroacupuncture applied to GV 20 in spontaneously **hypertensive** rats attenuated early stage blood pressure elevation and enhanced plasma levels of nitric oxide and nitric oxide synthase values in the mesenteric resistance artery.[17]
- Acupuncture at LI 4, LI 11, BL 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an **immunomodulatory** effect for patients with **lichen ruber planus.**[18]
- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly improved **postmenopausal** hot flushes and sweating episodes.[19]
- Electroacupuncture at CV 4, GV 20, SP 6, KI 3, and HT 7 may have afforded a modulating positive effect on psychogenic and non-psychogenic **erectile dysfunction.** It improved the quality of erection and restored sexual activity in 39% of patients.[20]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in improvement in **sperm quality,** specifically in the ultrastructural integrity of spermatozoa.[21]

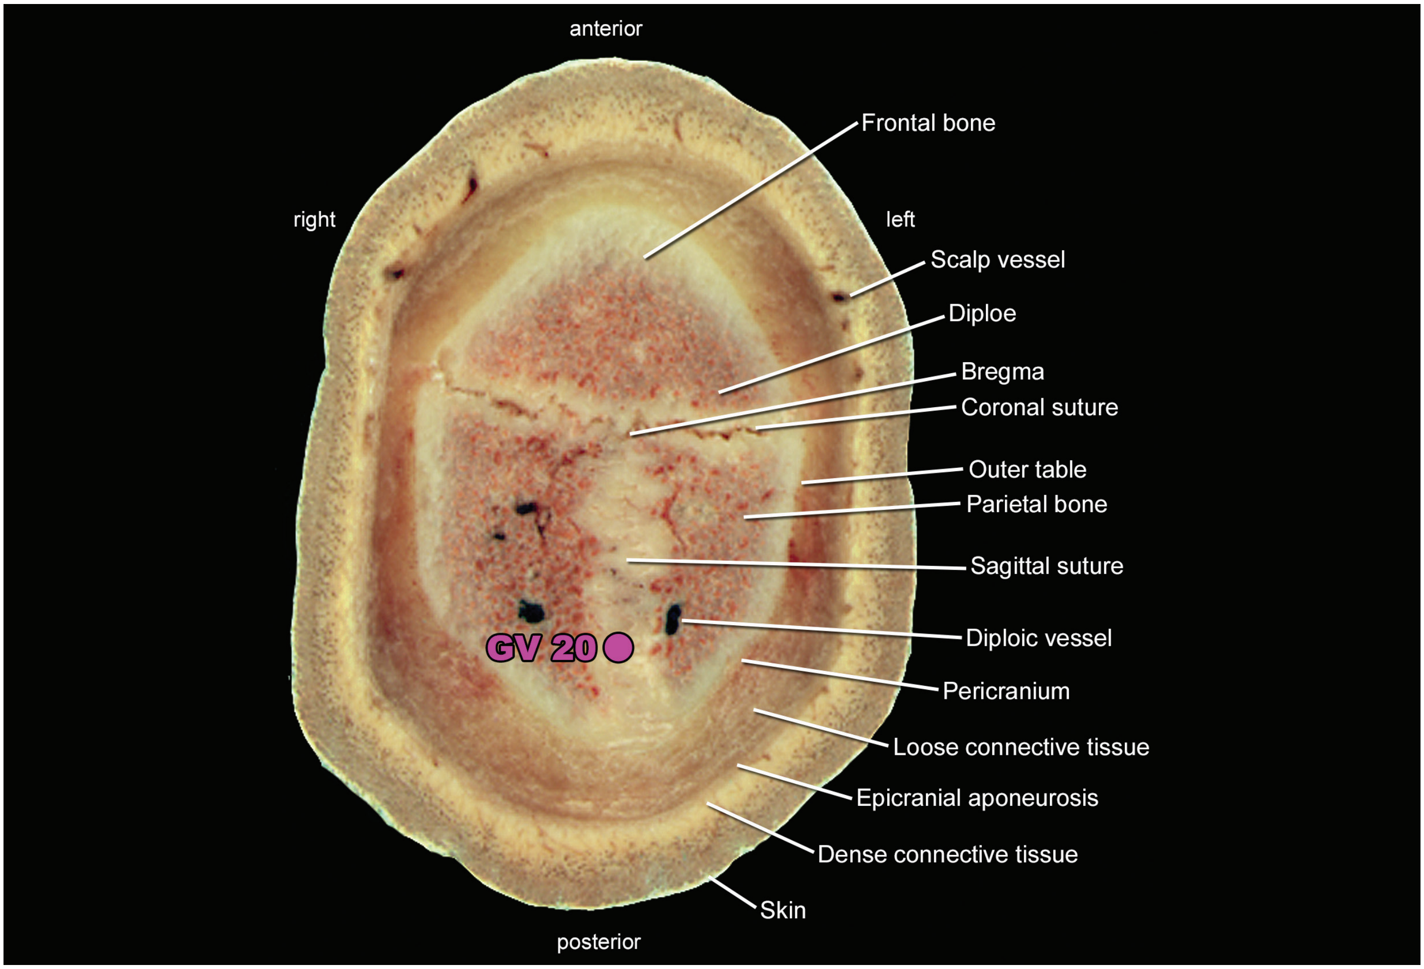

Figure 14-60. This cross section at the level of the bone and pericranium illustrates the highly vascular nature of the skull, not only at the sutures but within the bones as well.

- Electroacupuncture (at ST 29 and TH 5 to LI 4) with manual acupuncture at GV 20 and ST 36 serve as an effective **analgesic during oocyte aspiration;** these analgesic effects equal those of conventional analgesics.[22] Neuropeptide Y (NPY) concentrations in follicular fluid were higher in the electroacupuncture group than in the medication group; NPY may be important for human ovarian steroidogenesis.[23]
- Electroacupuncture (at BL 23, BL 28, SP 6, and SP 9) in combination with manual acupuncture (at PC 6, TH 5, and GV 20) induced regular ovulations in some women with **polycystic ovary syndrome,** thereby offering an alternative to pharmacologic induction of ovulation.[24]
- Acupuncture at GV 20, CV 6, ST 29, SP 8, PC 6, LR 3, auricular points Shenmen and Brain on the left ear, auricular points Uterus and Endocrine on the right ear (before embryo transfer) and LI 4, SP 10, ST 36, SP 6, KI 3, and the aforementioned auricular points on the opposite ears (after embryo transfer) resulted in higher numbers of **live births following in vitro fertilization.**[57]
- Acupuncture at GV 20, Yintang (GV 24.5), PC 6, HT 7, and CV 17 significantly reduced **anxiety** symptoms in women undergoing in vitro fertilization.[58]
- Case series reported successful treatment of **enuresis, urinary incontinence, and urinary retention** with GV 20.[25]
- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis.**[26]
- Acupuncture at GV 20 and LR 3, local points, and either BL 60 + SI 3, BL 22 –> BL 26, the gluteus minimus tendon, or the symphysis pubis, provided effective relief of **pelvic and low back pain in late pregnancy.**[27]
- Manual acupuncture at GV 20, LI 4, CV 3, CV 4, CV 6, BL 23, SP 6, and auricular points allowed women with primary **dysmenorrhea** to reduce reliance on medication to control symptoms by means of neuroendocrine modulation.[28]
- Acupuncture at GV 20, ST 36, SP 6, LR 3, PC 6, CV 2, CV 6, CV 12, LI 4, and LI 11 provided effective relief of myalgia, mastalgia, and dysmenorrheal complaints in patients with **premenstrual syndrome.**[59]
- Acupuncture at GV 20, SP 4, and PC 6 alleviated **refractory nausea, abdominal pain, and bloating.**[60]
- Acupuncture at GV 20 and thirteen other sites may assist in improving exercise performance and **post-exercise recovery.**[61]

GV 21

Qian Ding "In Front of the Crown" "Before the Vertex"

On the parietal region on the midsagittal line, 1.5 cun rostral to GV 20, 3.5 cun caudal to the rostral hairline.

Location Tip: Divide the distance between GV 20 and the rostral hairline into thirds. GV 21 lies just caudal to the junction between the most caudal and middle thirds. See Figure 14-61B.

If the anterior hairline is poorly demarcated, designate the hairline's location 3 cun superior to the glabella.

Cranial Suture

- **Sagittal suture:** This midline cranial suture serves as a rough external landmark for the underlying superior sagittal sinus. At its caudal extent, the superior sagittal sinus often deviates to the right, tending to drain more frequently into the right transverse sinus.[1]

Clinical Relevance: Cranial sutures allow for changes in the size and conformation of the skull. When maintained in the adult, sutural mobility accommodates cranial expansion and contraction with intracranial pressure changes. In addition, flexible sutures modulate strain placed on the skull by calvarial muscle contraction during mastication.

Myofascial dysfunction that pulls on cranial sutures can invoke pain and neurovascular dysfunction by compressing nerves and vessels. Sutural compaction activates extracranial nociceptors of meningeal origin that supply the sutures. These fibers relay signals back and forth across the calvarium.[2,3] Sensory fibers that innervate the lambdoid, coronal, and squamous sutures of the calvarium do the same.[4]

Bidirectional communication mediated by meningeal nociceptors helps to explain how myofascial tension and inflammation in the temporalis, occipitofrontalis, and epicranial aponeurosis incites intracranial pain. Disturbances in the skin, connective tissue, and periosteum may in turn also instigate headache. Conversely, some patients with migraine, considered a source of intracranial pain, complain that their skull hurts, and not their "brain".[5]

The fact that nociceptors from the dura innervate cranial sutures introduces opportunities for neuromodulation, either directly along the GV line as in the case of the sagittal suture, or indirectly through cervical and trigeminal nerves that cross talk with dural fibers. GV 20, called "Hundred Convergences", interacts with both trigeminal and vagal extracranial afferents, accounting for its notoriety as a strong point that calms patients. GV 21, in contrast, relates more closely with trigeminal rather than upper cervical nerves, as its "In Front of the Crown" position brings it out of occipital nerve territory. (See Figure 14-61A.)

Connective Tissues

Connective Tissues of the **"SCALP"**, consisting of 5 layers, i.e., **S**kin, **C**onnective tissue (dense), **A**poneurosis, **L**oose connective tissue, and **P**ericranium

- **Skin:** Contains an abundant arterial supply as well as good venous and lymphatic drainage capacity.
- **Dense connective tissue:** Comprises the thick and well-vascularized subcutaneous layer, richly supplied with cutaneous nerves.
- **Galea aponeurotica (epicranial aponeurosis):** This strong, tendinous sheet, or aponeurosis, covers the calvaria and connects the occipitalis, superior auricular, and frontalis muscles; the collective term for this structure is the "epicranius muscle".
- **Loose connective tissue:** Resides beneath the galea aponeurotica, affording many potential spaces that may distend with fluid following infection or trauma.
- **Pericranium:** This is the external periosteum of the calvaria, continuous with the fibrous tissue in the cranial sutures.

Clinical Relevance: Scalp needling requires caution; the loose connective tissue layer constitutes the "danger area of the scalp", as infection from this layer may enter the cranium by way of emissary veins that course through calvarial foramina.

Lacerations of the scalp may bleed profusely as a consequence of the abundance of arterial anastomoses in the scalp. These arteries fail to retract when cut because the dense connective tissue in the scalp maintains patency of the artery walls.

Nerves

- **Auriculotemporal nerve (CN V_3):** Provides sensory innervation to the skin anterior to the ear, along the posterior temporal region, the tragus, and part of the helix of the auricle. Provides sensation to the roof of the external acoustic meatus and the upper portion of the tympanic membrane.
- **Supraorbital nerve (CN V_1):** The supraorbital nerve is a continuation of the frontal nerve, innervates the mucous membrane of the frontal sinus and the upper eyelid conjunctiva, and provides sensation to the forehead skin and vertex.

Clinical Relevance: The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[6] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can occur at GB points on the side of the head and elsewhere along the neurovascular course. Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[7] From a trigger point perspective, although muscles are largely absent from the vertex, dysfunction in the sternocleidomastoid (sternal head) and the splenius capitis sometimes refer pain to the top of the head, from GV 19 to GV 21. As such, patients presenting with vertex pain may be harboring trigger points in the cervical musculature.

The auriculotemporal nerve also impacts balance. Stomatognathic disorders, i.e., problems with mouth, teeth, mandible, pharynx, and other structures associated with mastication, speech, and deglutition, negatively impact posture, balance, and gait.

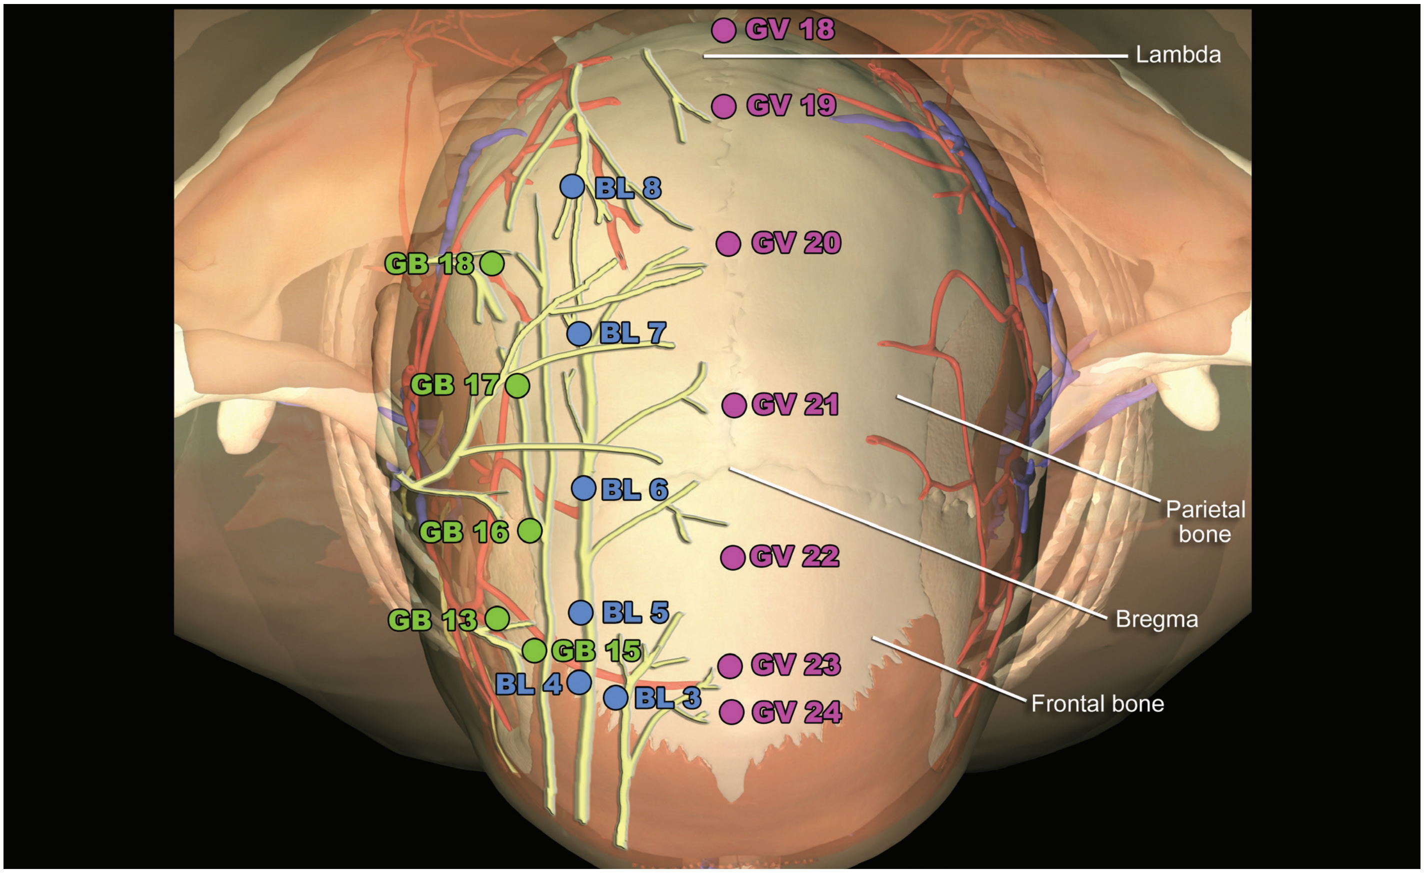

Figure 14-61A. The view of the vertex shows the interrelationships of points on the scalp. With GV 20 stipulated as the vertex, GV 21 becomes "Before the Vertex" and GV 19 "Behind the Vertex". Palpation along the sagittal suture, from lambda to bregma, may reveal tenderness in patients with headache. Pain may originate from extracranial myofascial dysfunction, sutural irritation, or dural irritation.

Muscle reflex responses controlling balance and equilibrium depend on input into the reticular formation from several sources. Afferents arise from trigeminal, auditory, proprioceptive, visual, vestibular, cutaneous, and autonomic pathways. The extensive reticular formation in the brainstem integrates this information, couples it with input from the brain, and forwards it to brainstem nuclei that oversee sensation, motor activity, and autonomic function. Afferent information makes its way to the nucleus raphe magnus in the reticular formation via the spinal tract of V. These inputs can influence reflex arcs and motor responses from the face and cranium.

Painful dentition and abnormal TMJ mechanics send nociceptive input that may sensitize neural pathways related to auriculotemporal nerve pathways. These facilitated reflexes between the reticulospinal and nucleus raphe magnus tracts may lead to involuntary rhythmic tremors, gait disturbances, and postural imbalance. In this way, afferent impulses transmitted through trigeminal nerve circuitry have the capacity to change tonic or "resting" activity within the reticular formation. Altered tonic activity impacts the nature of eye movements, posture, respiration, arousal, sleep, pain, vasomotor tone, cardiac output, feeding, and homeostasis in general.

Taking all of these reflexes into account, trigeminal nerve input ferried through the auriculotemporal nerve works alongside sensory, oculomotor, and vestibular afferents to manage a variety of highly coordinated activities.

Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of

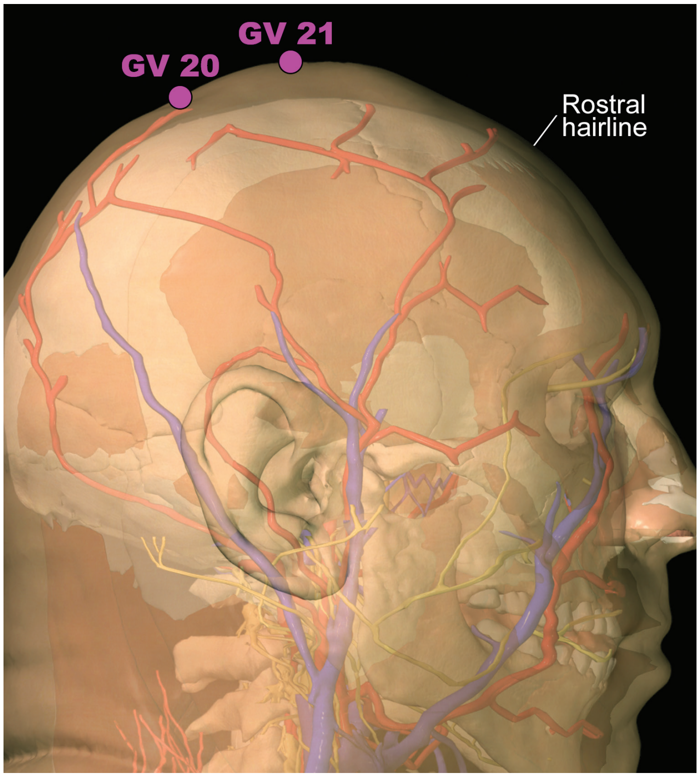

Figure 14-61B. Despite the name "Before the Vertex" for GV 21, this lateral view of the head reveals that GV 21, not GV 20, sits at the highest spot on the cranium. GV 21 resides one-third the distance from GV 20 to the rostral (anterior) hairline.

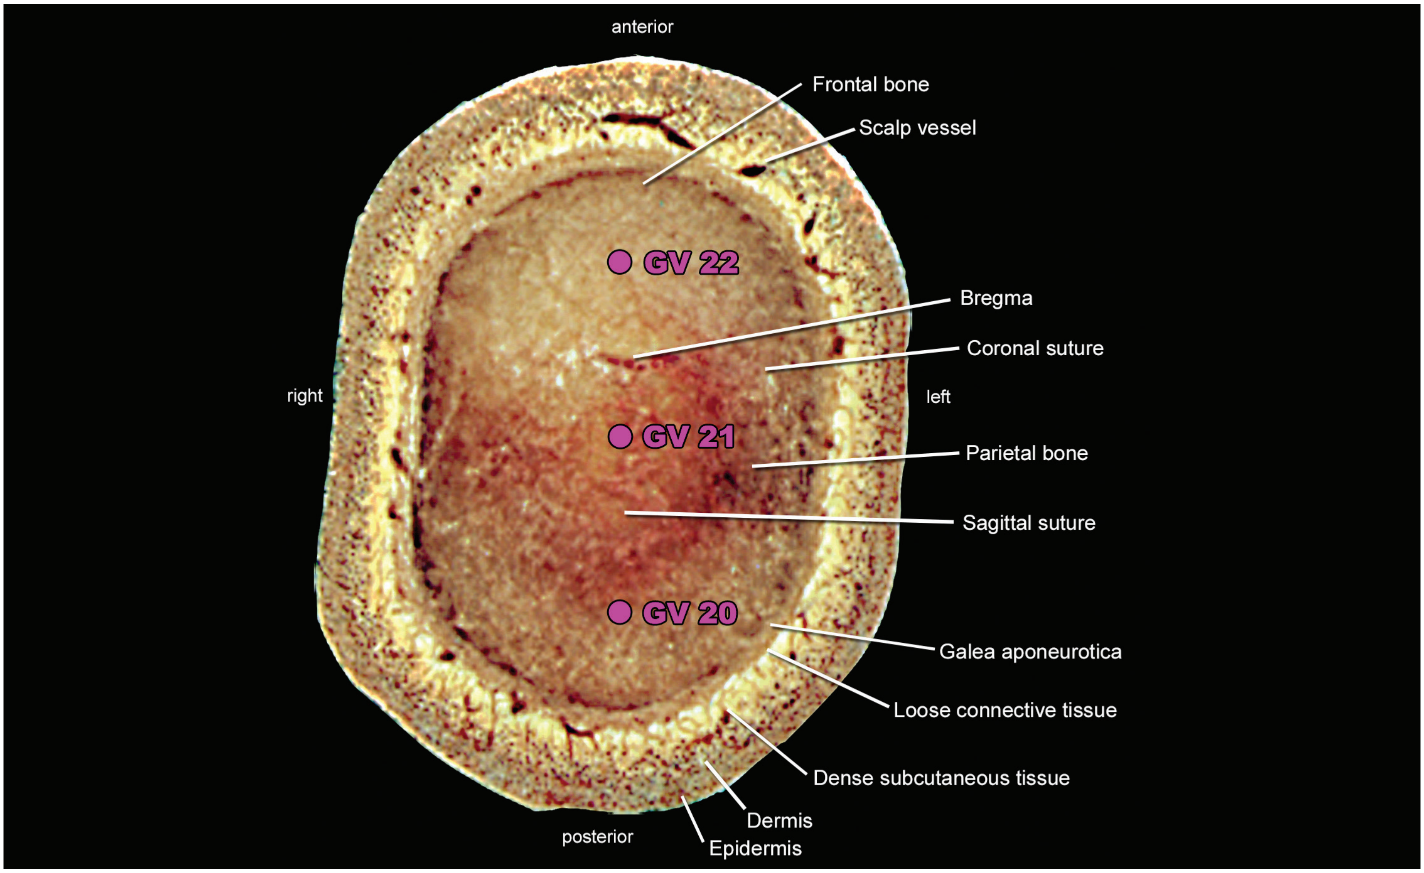

Figure 14-62. Scalp lacerations bleed profusely. Examine the prolific vasculature occupying the dense connective tissue in this cross-section at the vertex.

the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel and includes the midline GV channel) to the vertex.[8] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through trigeminosympathetic reflexes.

Similar syndromes to SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, and other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (i.e., at the supraorbital notch). Dry needling of BL 2, BL 7, GV 21, GV 20, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

Vessels

- **Anastomosis between right and left parietal branches of the superficial temporal arteries:** The superficial temporal arteries begin as terminal branches of the external carotid arteries and ascend anterior to the ear, course over the temporal region, and terminate in the scalp. They bring blood circulation to the facial muscles and the skin of the frontal and temporal regions of the scalp.
- **Anastomosis between right and left parietal tributaries of the superficial temporal veins:** The superficial temporal veins originate from the widespread plexus of veins coursing on the side of the scalp and along the zygomatic arch. The parietal tributaries drain the parietal region and unite with the frontal branches anterior to the auricle. They then cross the temporal root of the zygoma and travel from the temporal region to the parotid gland. They then join the maxillary vein posterior to the neck of the mandible and become the retromandibular vein.
- **Anastomosis between right and left supraorbital arteries:** The supraorbital arteries arise from the ophthalmic arteries and pass through the supraorbital foramina to supply the forehead and scalp.
- **Anastomosis between right and left supraorbital veins:** The supraorbital veins drain the rostral superficial scalp through the supraorbital and supratrochlear veins, which unite at the medial angle of the eye to form the angular vein. The angular vein becomes the facial vein at the inferior orbital margin.
- **Emissary veins:** These veins connect the dural venous sinuses with the extracranial veins. Emissary veins lack valves, and blood may flow in either direction, though usually its flow is from the brain outward. Emissary veins vary in size and number. Children have a frontal emissary vein that may persist in some adults. The frontal emissary vein connects the superior sagittal sinus with the frontal sinus and nasal cavities. Parietal emissary veins may occur in pairs, passing through the parietal foramina in the calvaria and allowing flow between the superior sagittal sinus and the veins of the scalp. Occipital or posterior auricular

veins connect with the sigmoid sinus via the mastoid emissary veins, which course through the mastoid foramina.

Clinical Relevance: The superior sagittal sinus closely follows the course of the GV line as indicated in Figure 14-61A. Embryologically, the superior sagittal sinus begins as two parallel structures that merge. The lateral lacunae that lie on either side of the sinus may represent remnants of the early double plexus. Their locations vary. The lacunae function as autoregulators of blood flow as they control venous outflow resistance. Pathology within the lateral lacunae of the sagittal sinus compromises this draining activity. This may lead to brain swelling by reducing venous outflow. Lateral lacunae stenosis, which occurs in young women with endocrine disorders, can lead to benign intracranial hypertension.[9]

Arachnoid villi (or arachnoid granulations) are protrusions of the arachnoid layer of the meninges, through the dura mater, and into the venous sinuses of the brain. The arachnoid villi provide an exit route for cerebrospinal fluid (CSF) from the brain and into the venous system. The largest arachnoid villi occur along the superior sagittal venous sinus. Under normal circumstances, CSF draining from arachnoid villi keeps intracranial pressure from building.

Pain-sensitive fibers from the ophthalmic division of the trigeminal nerve supply sensation to the venous sinuses. These sinuses include the superior sagittal sinus, the meningeal arteries, and much of the supratentorial dura. Trigeminal fibers also supply the circle of Willis and other cerebral arteries as they join fibers from the sympathetic plexus. Trigeminal nerve irritation is central in the pathophysiology of head and facial pain.[10]

Supraorbital vessels anastomose with superficial temporalis vasculature. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and irritating nerves.

Indications and Potential Point Combinations

- **Headache referring to the vertex:** GV 21, GV 20, BL 7, BL 6, BL 10, LU 7, LI 4.
- **Vertigo, dizziness:** GV 21, GV 20, BL 10, GB 20, GB 18, LR 3, ST 36.
- **Seizures:** GV 21, BL 6, BL 8, BL 60, GV 20, ST 11, CV 17, ST 36.

GV 22

Xin Hui "Fontanelle Meeting"

On the midsagittal line, 3 cun rostral to GV 20.

Measure the distance between GV 20 and the rostral hairline; GV 22 lands, 0.5 cun rostral to the midpoint of this distance.

One cun posterior to GV 23.

Forbidden to needle in small children.

Anterior Fontanelle (in juvenile patients)

- Whereas cranial sutures in the adult harbor narrow seams of fibrous connective tissue between the flat bones of the skull, the fontanelles consist of fibrous, membrane-covered gaps between three or more juxtaposed cranial bones. The superior sagittal dural venous sinus resides beneath the anterior and posterior fontanelles.

This "soft spot" found on a baby's head allows the plates of the skull to move and thereby accommodate the spatial restrictions imposed by the birth canal. Fontanelles ordinarily close by the second year of life in human children; cranial sutures and sutural intersections replace them. Newborn skulls exhibit six fontanelles: a small posterior fontanelle at lambda (where the two parietal bones join the occipital bone near GV 18); the large, diamond- or rhomboid-shaped anterior fontanelle at the juncture of the two parietal bones with the paired frontal bones); two sphenoid fontanelles located where the sphenoid, parietal, temporal, and frontal bones intersect; and finally, the two mastoid fontanelles that appear between the temporal, occipital, and parietal bones. Eventually, these fontanelles close and leave behind cranial intersections, or sutures, as seen in Figure 14-63.

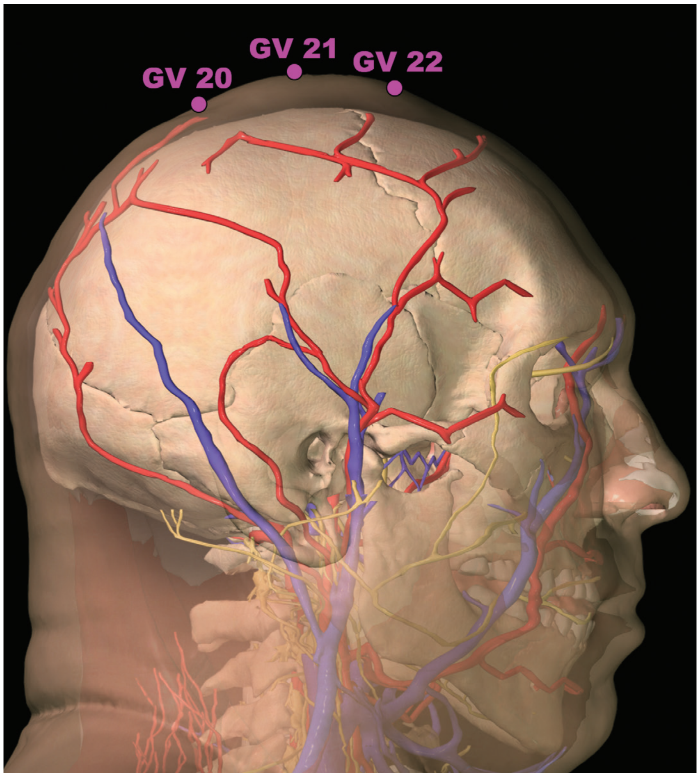

Figure 14-63. By GV 22, the GV channel has moved from the parietal to the frontal bone. No longer does the GV line fall along a suture. This limits the ability to neuromodulate extracranial collaterals of meningeal nociceptors. However, stimulation of GV 22 does activate branches of the ophthalmic division of the trigeminal nerve by way of the supraorbital nerve, thereby neuromodulating the ophthalmic division, which also supplies the dura.

The term "fontanelle" originated from the acknowledgement that fontanelles exhibit pulsations when palpated; their rhythm seems to coincide with the arterial pulse. Fontanelle means "little fountain" and reflects the movement of fluid found at this site. In addition, the condition commonly known as "water on the brain", i.e., hydrocephalus, manifests as a bulge at the fontanelle(s), caused by elevated intracranial pressure.

Other causes of abnormally large fontanels include hypothyroidism, Down syndrome, achondroplasia, and rickets. A bulging anterior fontanelle may occur due to elevated intracranial pressure, and tumors within or atop the calvarium.[1]

Clinical Relevance: Before needling GV 22, GV 23, or the anywhere over the calvarium, ensure through palpation that the brain is protected by bone. Fontanelles may enlarge or never close due to various causes, including Down syndrome, hydrocephalus, intrauterine growth retardation, or premature birth, among others. Furthermore, cranial defects may follow neurosurgical procedures. Obtain information about prior neurosurgical events during the history and ascertain cranial integrity through palpation prior to inserting needles at GV, BL, ST, or GB points.

Connective Tissues

Connective Tissues of the **"SCALP"**, consisting of 5 layers, i.e., **S**kin, **C**onnective tissue (dense), **A**poneurosis, **L**oose connective tissue, and **P**ericranium

- **Skin:** Contains an abundant arterial supply as well as good venous and lymphatic drainage capacity.
- **Dense connective tissue:** Comprises the thick and well-vascularized subcutaneous layer, richly supplied with cutaneous nerves.
- **Galea aponeurotica (epicranial aponeurosis):** This strong, tendinous sheet, or aponeurosis, covers the calvaria and connects the occipitalis, superior auricular, and frontalis muscles; the collective term for this structure is the "epicranius muscle".
- **Loose connective tissue:** Resides beneath the galea aponeurotica, affording many potential spaces that may distend with fluid following infection or trauma.
- **Pericranium:** This is the external periosteum of the calvaria, continuous with the fibrous tissue in the cranial sutures.

Clinical Relevance: Scalp needling requires caution; the loose connective tissue layer constitutes the "danger area of the scalp", as infection from this layer may enter the cranium by way of emissary veins that course through calvarial foramina.

Lacerations of the scalp may bleed profusely as a consequence of the abundance of arterial anastomoses in the scalp. These arteries fail to retract when cut because the dense connective tissue in the scalp maintains patency of the artery walls.

Nerves

- **Auriculotemporal nerve (CN V_3):** Provides sensory innervation to the skin anterior to the ear, along the posterior temporal region, the tragus, and part of the helix of the auricle. Provides sensation to the roof of the external acoustic meatus and the upper portion of the tympanic membrane.

- **Supraorbital nerve (CN V_1):** The supraorbital nerve is a continuation of the frontal nerve, innervates the mucous membrane of the frontal sinus and the upper eyelid conjunctiva, and provides sensation to the forehead skin and vertex.

Clinical Relevance: The auriculotemporal nerve supplies sensation by means of numerous branches to the TMJ, the temporal region, and components of the external ear, including the pinna or auricle, the external acoustic meatus, and the parotid gland.[2] Its hitchhiking parasympathetic fibers from the glossopharyngeal nerve supply excretory influence to the buccal and labial glands. The numerous branches and hardworking muscles of mastication, compounded by the complex formation of the TMJ and vascular network in the infratemporal fossa create a "perfect storm" for nerve entrapment. Auriculotemporal nerve entrapment can cause TMJ pain syndromes, headaches, and pain or paresthesias in the external acoustic meatus and auricle.

Compression of the auriculotemporal nerve by preauricular fascial bands or intersecting superficial temporal vessels can occur at GB points on the side of the head and elsewhere along the neurovascular course. Tension and pressure applied to these crossovers may cause headache and act as an anatomical trigger for migraine.[3] From a trigger point perspective, although muscles are largely absent from the vertex, dysfunction in the sternocleidomastoid (sternal head) and the splenius capitis sometimes refer pain to the top of the head, from GV 19 to GV 22. As such, patients presenting with vertex pain may be harboring trigger points in the cervical musculature.

The auriculotemporal nerve also impacts balance. Stomatognathic disorders, i.e., problems with mouth, teeth, mandible, pharynx, and other structures associated with mastication, speech, and deglutition, negatively impact posture, balance, and gait.

Muscle reflex responses controlling balance and equilibrium depend on input into the reticular formation from several sources. Afferents arise from trigeminal, auditory, proprioceptive, visual, vestibular, cutaneous, and autonomic pathways. The extensive reticular formation in the brainstem integrates this information, couples it with input from the brain, and forwards it to brainstem nuclei that oversee sensation, motor activity, and autonomic function. Afferent information makes its way to the nucleus raphe magnus in the reticular formation via the spinal tract of V. These inputs can influence reflex arcs and motor responses from the face and cranium.

Painful dentition and abnormal TMJ mechanics send nociceptive input that may sensitize neural pathways related to auriculotemporal nerve pathways. These facilitated reflexes between the reticulospinal and nucleus raphe magnus tracts may lead to involuntary rhythmic tremors, gait disturbances, and postural imbalance. In this way, afferent impulses transmitted through trigeminal nerve circuitry have the capacity to change tonic or "resting" activity within the reticular formation. Altered tonic activity impacts the nature of eye movements, posture, respiration, arousal, sleep, pain, vasomotor tone, cardiac output, feeding, and homeostasis in general.

Taking all of these reflexes into account, trigeminal nerve input ferried through the auriculotemporal nerve works alongside sensory, oculomotor, and vestibular afferents to manage a variety of highly coordinated activities.

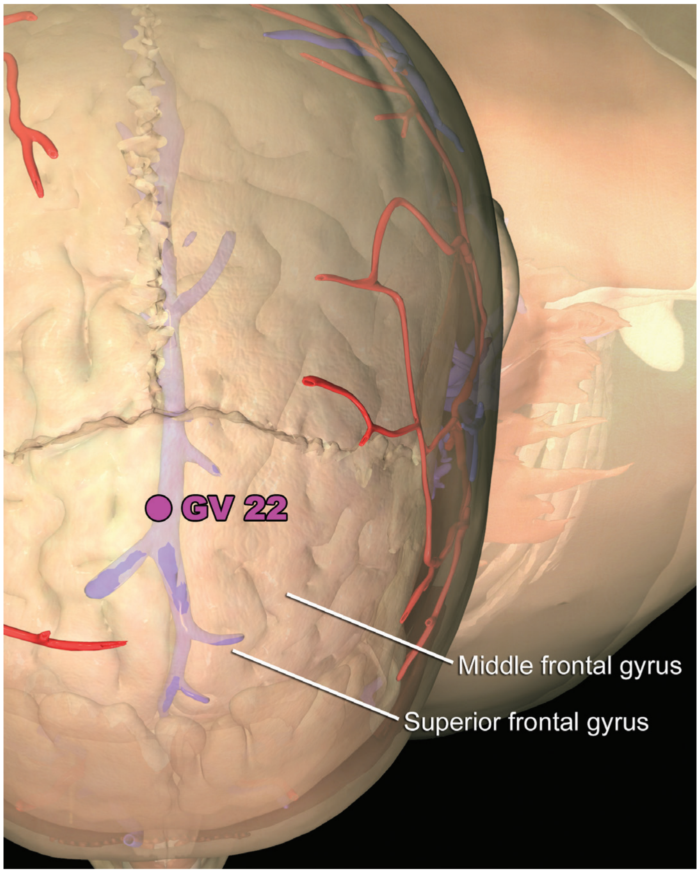

Figure 14-64. The name "Fontanelle Meeting" for GV 22 describes its relationship to the anterior fontanelle, explaining why needling this point is contraindicated in babies or young children with an open anterior fontanelle. Before the sutures ossify and join the frontal bones with the parietal, GV 22 coincides with the "soft spot" of the skull.

Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel and includes the midline GV channel) to the vertex.[4] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through trigeminosympathetic reflexes.

Similar syndromes to SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, and other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (i.e., at the supraorbital notch). Dry needling of BL 2, BL 7, GV 21, GV 22, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

The superior frontal gyrus, labeled in Figure 14-64, contributes to higher cognitive function and working memory, highlighting the role of the frontal cortex in the highest level of executive processing. It also participates in spatially oriented processing.[5] However, it appears that the lateral, but not the medial, aspect of the superior frontal gyrus belongs to the working memory network. This becomes relevant when neurosurgeons remove low-grade gliomas affecting the superior frontal gyrus, as well as opportunities for laser therapy neuromodulation for supporting function during high cognitive demand or restoring memory after brain injury. Remember, too, that laser therapy and other forms of neuromodulation may improve local blood supply and drainage, thereby affecting circulation and oxygen delivery to the superior frontal gyrus by dint of treatment at GV 22.

Vessels

- **Anastomosis between right and left parietal branches of the superficial temporal arteries:** The superficial temporal arteries begin as terminal branches of the external carotid arteries and ascend anterior to the ear, course over the temporal region, and terminate in the scalp. They bring blood circulation to the facial muscles and the skin of the frontal and temporal regions of the scalp.
- **Anastomosis between right and left parietal tributaries of the superficial temporal veins:** The superficial temporal veins originate from the widespread plexus of veins coursing on the side of the scalp and along the zygomatic arch. The parietal tributaries drain the parietal region and unite with the frontal branches anterior to the auricle. They then cross the temporal root of the zygoma and travel from the temporal region to the parotid gland. They then join the maxillary vein posterior to the neck of the mandible and become the retromandibular vein.
- **Anastomosis between right and left supraorbital arteries:** The supraorbital arteries arise from the ophthalmic arteries and pass through the supraorbital foramina to supply the forehead and scalp.
- **Anastomosis between right and left supraorbital veins:** The supraorbital veins drain the rostral superficial scalp through the supraorbital and supratrochlear veins, which unite at the medial angle of the eye to form the angular vein. The angular vein becomes the facial vein at the inferior orbital margin.
- **Emissary veins:** These veins connect the dural venous sinuses with the extracranial veins. Emissary veins lack valves, and blood may flow in either direction, though usually its flow is from the brain outward. Emissary veins vary in size and number. Children have a frontal emissary vein that may persist in some adults. The frontal emissary vein connects the superior sagittal sinus with the frontal sinus and nasal cavities. Parietal emissary veins may occur in pairs, passing through the parietal foramina in the calvaria and allowing flow between the superior sagittal sinus and the veins of the scalp. Occipital or posterior auricular veins connect with the sigmoid sinus via the mastoid emissary veins, which course through the mastoid foramina.

Clinical Relevance: The superior sagittal sinus closely follows the course of the GV line as indicated in Figure 14-61A. Embryologically, the superior sagittal sinus begins as two parallel structures that merge. The lateral lacunae that lie on either side of the sinus may represent remnants of the early double plexus. Their locations vary. Lacunae function as autoregulators of blood flow as they control venous outflow resistance. Pathology within the lateral lacunae of the sagittal sinus compromises this draining activity. This may lead to brain swelling by reducing venous outflow. Lateral lacunae stenosis, which occurs in young women with endocrine disorders, can lead to benign intracranial hypertension.[6]

Arachnoid villi (or arachnoid granulations) are protrusions of the arachnoid layer of the meninges, through the dura mater, and into the venous sinuses of the brain. The arachnoid villi provide an exit route for cerebrospinal fluid (CSF) from the brain and into the venous system. The largest arachnoid villi occur along the superior sagittal venous sinus. Under normal circumstances, CSF draining from arachnoid villi keeps intracranial pressure from building.

Pain-sensitive fibers from the ophthalmic division of the trigeminal nerve supply sensation to the venous sinuses. These sinuses include the superior sagittal sinus, the meningeal arteries, and much of the supratentorial dura. Trigeminal fibers also supply the circle of Willis and other cerebral arteries as they join fibers from the sympathetic plexus. Trigeminal nerve irritation is central in the pathophysiology of head and facial pain.[7] Neuromodulation of trigeminal nerve function by dint of acupuncture and related techniques to rostral GV points over the calvarium may improve blood flow to and from the brain.

Supraorbital vessels anastomose with superficial temporalis vasculature. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and irritating nerves.

Indications and Potential Point Combinations

- **Headache:** Palpate in the vicinity of GV 22 and other points along the sagittal suture in patients complaining of headache at the vertex. Consider BL 10, GB 21, LI 4, and additional trigger points pertinent to the patient's pain problem.
- **Seizures:** GV 22, GV 20, ST 11, ST 36, GB 13, BL 10, LR 2.
- **Rhinitis:** GV 22, GV 24.5 (Yintang), LI 20, ST 44.
- **Anosmia:** GV 22, GV 23, GV 20, BL 6, LI 20.
- **Hangover headache:** GV 22, GV 24.5, GV 20, Taiyang (center of temporal region), GB 14, LI 4, PC 6, ST 36, LR 3.

GV 23

Shang Xing "Upper Star"

On the frontal region, on the midsagittal line, 4 cun rostral to GV 20. Approximately 1 cun behind the anterior hairline or 0.5 cun posterior to GV 24.

Connective Tissues

Connective Tissues of the **"SCALP"**, consisting of 5 layers, i.e., **S**kin, **C**onnective tissue (dense), **A**poneurosis, **L**oose connective tissue, and **P**ericranium

- **Skin:** Contains an abundant arterial supply as well as good venous and lymphatic drainage capacity.
- **Dense connective tissue:** Comprises the thick and well-vascularized subcutaneous layer, richly supplied with cutaneous nerves.
- **Galea aponeurotica (epicranial aponeurosis):** This strong, tendinous sheet, or aponeurosis, covers the calvaria and connects the occipitalis, superior auricular, and frontalis muscles; the collective term for this structure is the "epicranius muscle".
- **Loose connective tissue:** Resides beneath the galea aponeurotica, affording many potential spaces that may distend with fluid following infection or trauma.
- **Pericranium:** This is the external periosteum of the calvaria, continuous with the fibrous tissue in the cranial sutures.

Clinical Relevance: Scalp needling requires caution; the loose connective tissue layer constitutes the "danger area of the scalp", as infection from this layer may enter the cranium by way of emissary veins that course through calvarial foramina.

Lacerations of the scalp may bleed profusely as a consequence of the abundance of arterial anastomoses in the scalp. These arteries fail to retract when cut because the dense connective tissue in the scalp maintains patency of the artery walls.

Nerves

- **Supratrochlear nerve (CN V$_1$):** The supratrochlear nerve is a branch of the frontal nerve that ascends medial to the supraorbital nerve and subsequently divides into two or more branches. It provides skin sensation in the region extending from the mid-forehead to the area near the hairline.
- **Supraorbital nerve (CN V$_1$):** The supraorbital nerve is a continuation of the frontal nerve, innervates the mucous membrane of the frontal sinus and the upper eyelid conjunctiva, and provides sensation to the forehead skin and vertex.

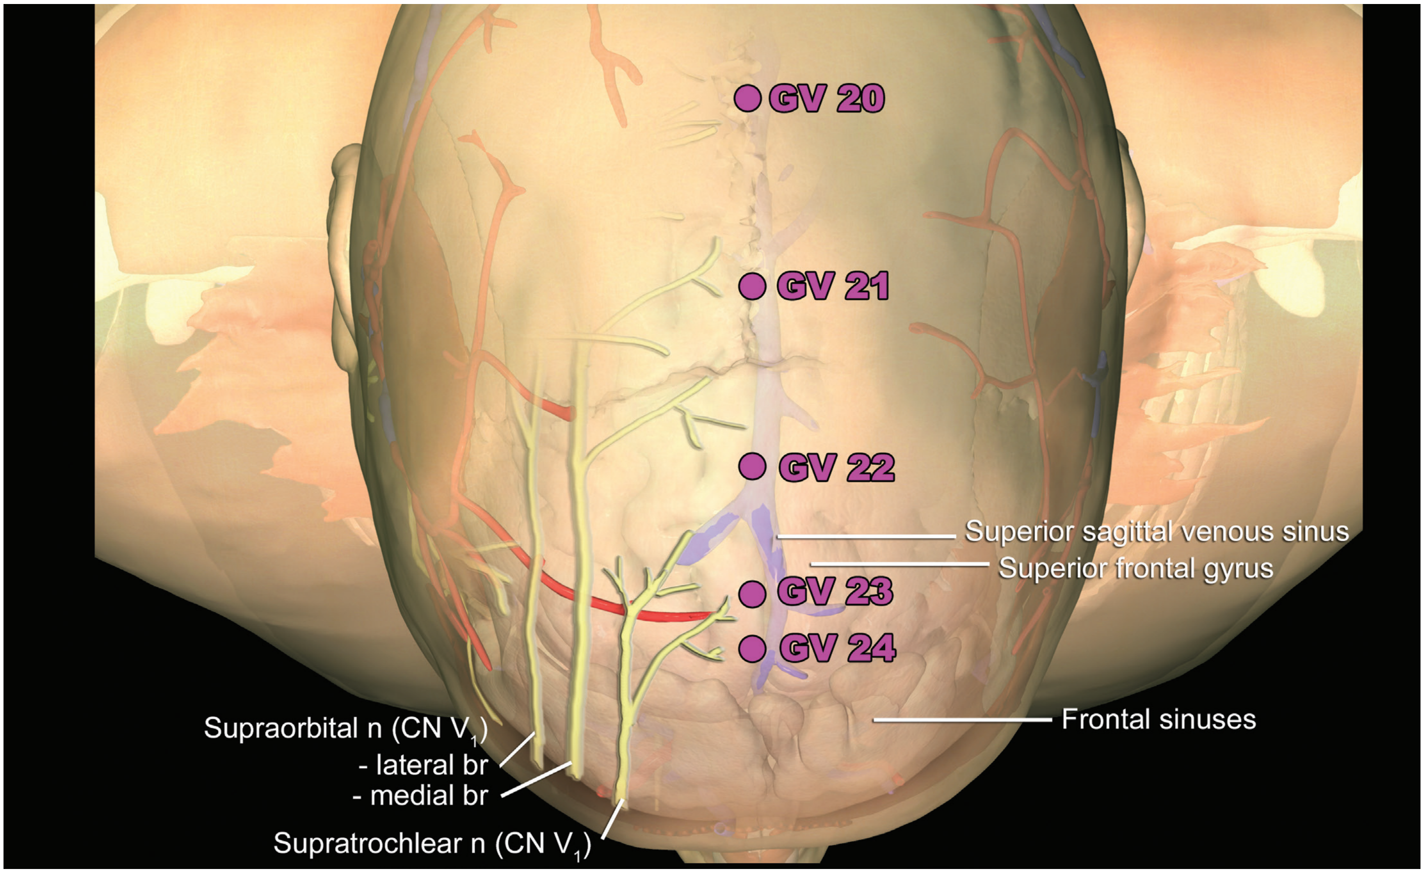

Figure 14-65. The dual supraorbital and supratrochlear innervation of GV 23 builds a somatic afferent conduit for neuromodulates of pain and autonomic dysfunction affecting the frontal sinuses, eyes, rostral dura, and local soft tissues. GV 23 also relates to the prefrontal cortex in the rostral portion of the frontal lobes. The superior frontal gyrus, i.e., that section adjacent to GV 23, carries out executive function and participates in working memory. Executive function allows an individual to control conflicting thoughts and desires that, if left unchecked, might lead to socially unacceptable outcomes. Meditation and exercise deregulate or down-regulate activity in the prefrontal cortex. In so doing, these processes invite altered states of consciousness known as "transient hypofrontality", considered a possible prerequisite for creativity.[14,15] Thus, neuromodulation at GV 23 and GV 24 may benefit the prefrontal cortex by increasing cognitive flexibility rather than by merely affecting its behavior in a unidirectional fashion (i.e., up or down).

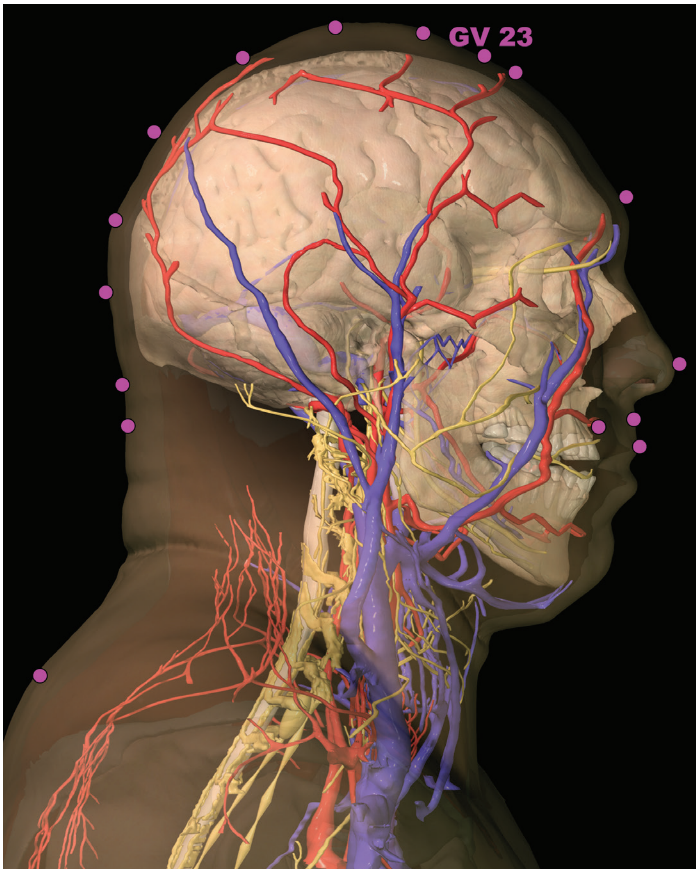

Figure 14-66. GV 23, the "Upper Star", appears here as a star in the upper portion of the GV constellation. Chinese medicine frequently includes astrological connotations and metaphors.

Clinical Relevance: Supraorbital/supratrochlear neuralgia, along with Infraorbital neuralgia and ophthalmic division trigeminal neuralgia, comprise neuralgic etiologies of pain in the periorbital tissues and forehead.[2]

Dysfunction in the supratrochlear nerve increases risk of migraine headache.[3] Peripheral nerve block of the supratrochlear, supraorbital, auriculotemporal, and the occipital nerves has been used to treat a variety of headache disorders, suggesting a role for acupuncture and related techniques in neuromodulating these pathways noninvasively for similar headache relief and clinical benefit.

Compression of the supratrochlear nerve by a tense corrugator muscle, frontalis, or procerus muscle may also precipitate migraine, arguing for alleviation of this pressure through acupuncture, manual therapy, and/or laser therapy well before attempting surgical decompression with corrugator supercilii transection, botulinum toxin injection, or other invasive maneuvers.[4,5,6]

Stimulation of the supraorbital and supratrochlear nerves can aid patients with otherwise intractable trigeminal autonomic cephalalgias (TAC).[7] While implanted stimulators may work, why not try for relief with noninvasive neuromodulation first?

Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel and includes the midline GV channel) to the vertex.[8] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, as well as migrainous features in some patients, depending on the extent of vascular involvement through trigeminosympathetic reflexes.

Syndromes similar to SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, and other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (i.e., at the supraorbital notch). Dry needling of BL 2, BL 7, GV 23, GV 24, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

The superior frontal gyrus, labeled in Figure 14-65, contributes to higher cognitive function and working memory, highlighting the role of the frontal cortex in executive processing. It also participates in spatially oriented processing.[9] However, it appears that the lateral, but not the medial, aspect of the superior frontal gyrus participates more strongly in the working memory network. This becomes relevant when neurosurgeons remove low-grade gliomas near the superior frontal gyrus. It also informs approaches involving laser therapy neuromodulation for brain injury. Laser therapy and other forms of neuromodulation may also improve local blood supply and venous drainage, supporting circulation and oxygen delivery to the superior frontal gyrus via GV 23 activation.

Vessels

- **Anastomosis between right and left supraorbital arteries:** The supraorbital arteries arise from the ophthalmic arteries and pass through the supraorbital foramina to supply the forehead and scalp.
- **Anastomosis between right and left supraorbital veins:** The supraorbital veins drain the rostral superficial scalp through the supraorbital and supratrochlear veins, which unite at the medial angle of the eye to form the angular vein. The angular vein becomes the facial vein at the inferior orbital margin.
- **Anastomosis between right and left supratrochlear arteries:** The supratrochlear arteries originate from the ophthalmic arteries and pass from the supraorbital margin to the scalp and the forehead.
- **Anastomosis between the right and left supratrochlear veins:** These veins begin on the forehead and scalp as a venous plexus and communicate with the superficial temporal veins and the supraorbital veins.
- **Emissary veins:** Emissary veins connect the dural venous sinuses to extracranial veins. Emissary veins lack valves, and blood may flow in either direction, though usually its flow is from the brain outward. Emissary veins vary in size and number. Children have a frontal emissary vein that may persist in some adults. The frontal emissary vein connects the superior sagittal sinus with the frontal sinus and nasal cavities. Parietal emissary veins may occur in pairs, passing through the parietal foramina

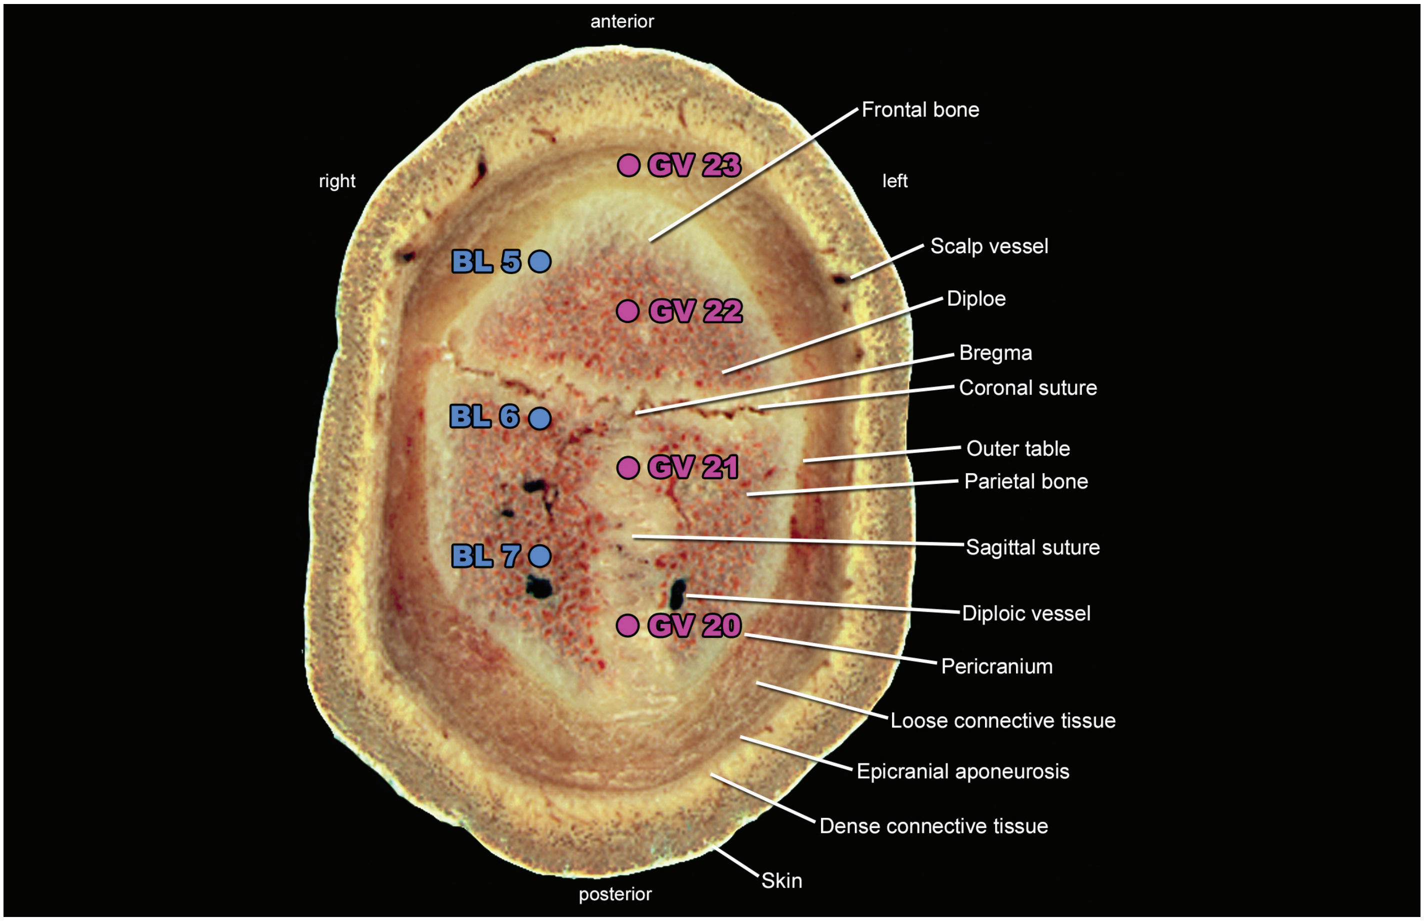

Figure 14-67. At GV 23, the GV channel begins its descent onto the face. In so doing, its neuromodulatory influence gains focus on facial, ocular, and upper respiratory dysfunction rather than brain behavior.

in the calvaria and allowing flow between the superior sagittal sinus and the veins of the scalp. Occipital or posterior auricular veins connect with the sigmoid sinus via the mastoid emissary veins, which course through the mastoid foramina.

Clinical Relevance: The superior sagittal sinus closely follows the course of the GV line as indicated in Figure 14-65. Embryologically, the superior sagittal sinus begins as two parallel structures that merge. The lateral lacunae that lie on either side of the sinus may represent remnants of the early double plexus. Their locations vary.

Lacunae function as autoregulators of blood flow as they control venous outflow resistance. Pathology within the lateral lacunae of the sagittal sinus compromises this draining activity. This may lead to brain swelling by reducing venous outflow. Lateral lacunae stenosis, which occurs in young women with endocrine disorders, can lead to benign intracranial hypertension.[10]

Arachnoid villi (or arachnoid granulations) are protrusions of the arachnoid layer of the meninges, through the dura mater, and into the venous sinuses of the brain. The arachnoid villi provide an exit route for cerebrospinal fluid (CSF) from the brain and into the venous system. The largest arachnoid villi occur along the superior sagittal venous sinus. Under normal circumstances, CSF draining from arachnoid villi keeps intracranial pressure from building.

Pain-sensitive fibers from the ophthalmic division of the trigeminal nerve supply sensation to the venous sinuses. These sinuses include the superior sagittal sinus, the meningeal arteries, and much of the supratentorial dura. Trigeminal fibers also supply the circle of Willis and other cerebral arteries as they join fibers from the sympathetic plexus.

Trigeminal nerve irritation is central in the pathophysiology of head and facial pain.[11] Neuromodulation of trigeminal nerve function by dint of acupuncture and related techniques to rostral GV points over the calvarium may improve blood flow to and from the brain.

Supraorbital vessels anastomose with superficial temporal vasculature. Note in Figure 14-65 the proximity of a frontal branch of the superficial temporal artery to the supraorbital and supratrochlear nerves. Conceivably, myofascial restriction in the occipitofrontalis and fascial planes could compress the vessel and nearby nerves, leading to reduced tissue oxygenation and neural irritation. Given that pulsations in the occipital artery incite neuropathic pain in overlapping occipital nerves, perhaps, pulsations in the superficial temporal artery could aggravate supraorbital or supratrochlear neuralgia where the two intersect.

Indications and Potential Point Combinations

- **Frontal sinusitis:** GV 23, GV 24.5, GB 14, BL 2, Taiyang, LI 4.
- **Epistaxis:** GV 23, GV 21, LI 20, LI 4.
- **Rhinitis:** GV 23, LI 20, LI 4.

- **Frontal headache:** GV 23, GV 24.5, BL 2, GB 14, GB 20, local tender trigger points, LI 4 or LU 7.
- **Eye pain:** GV 23, BL 2, TH 23, GB 1, GB 20, ST 36.
- **Anosmia:** GV 23, GV 22, GV 24.5, LI 20, ST 3.

Evidence-Based Applications

- A Chinese paper reported improvement in **facial spasm, trigeminal neuralgia, and "stubborn" facial paralysis** with GV 23, Yintang (GV 24.5), GB 20, GB 12, and BL 10. Putatively, stimulation at these points improved cerebral blood supply and vertebral basilar artery blood flow as well as relaxation of smooth muscle in cerebrovascular structures.[1]
- Acupuncture at GV 23, BL 2, GB 14, TH 23, Yintang (GV 24.5), ST 1, GB 20, LI 4, and LI 11 significantly improved ocular surface disease index and tear film break up time in patients with **dry eye.**[12]
- Acupuncture at GV 23, LI 20, LI 4, and Yintang significantly improved forced expiratory volume and asthma-related complaints in a patient with persistent **allergic rhinitis** complicated by **rhinosinusitis and asthma.**[13]

GV 24

Shen Ting "Courtyard of the Spirit"

On the frontal region, on the midsagittal line, 4.5 cun anterior to GV 20, approximately 0.5 cun behind the anterior hairline.

Connective Tissues

Connective Tissues of the **"SCALP"**, consisting of 5 layers, i.e., **S**kin, **C**onnective tissue (dense), **A**poneurosis, **L**oose connective tissue, and **P**ericranium

- **Skin:** Contains an abundant arterial supply as well as good venous and lymphatic drainage capacity.
- **Dense connective tissue:** Comprises the thick and well-vascularized subcutaneous layer, richly supplied with cutaneous nerves.
- **Galea aponeurotica (epicranial aponeurosis):** This strong, tendinous sheet, or aponeurosis, covers the calvaria and connects the occipitalis, superior auricular, and frontalis muscles; the collective term for this structure is the "epicranius muscle".
- **Loose connective tissue:** Resides beneath the galea aponeurotica, affording many potential spaces that may distend with fluid following infection or trauma.
- **Pericranium:** This is the external periosteum of the calvaria, continuous with the fibrous tissue in the cranial sutures.

Clinical Relevance: Scalp needling requires caution; the loose connective tissue layer constitutes the "danger area of the scalp", as infection from this layer may enter the cranium by way of emissary veins that course through calvarial foramina.

Lacerations of the scalp may bleed profusely as a consequence of the abundance of arterial anastomoses in the scalp. These arteries fail to retract when cut because the dense connective tissue in the scalp maintains patency of the artery walls.

The location of GV 24 at the myotendinous junction of the frontalis muscle and galea aponeurotica highlights its potential for helping alleviate tension headache.

Nerves

- **Supratrochlear nerve (CN V_1):** The supratrochlear nerve is a branch of the frontal nerve that ascends medial to the supraorbital nerve and subsequently divides into two or more branches. It provides skin sensation in the region extending from the mid-forehead to the area near the hairline.
- **Supraorbital nerve (CN V_1):** The supraorbital nerve is a continuation of the frontal nerve, innervates the mucous membrane of the frontal sinus and the upper eyelid conjunctiva, and provides sensation to the forehead skin and vertex.

Clinical Relevance: Supraorbital/supratrochlear neuralgia, along with infraorbital neuralgia and ophthalmic division trigeminal neuralgia, comprise neuralgic etiologies of pain in the periorbital tissues and forehead.[3]

Dysfunction in the supratrochlear nerve increases risk of migraine headache.[4] Peripheral nerve block of the supratrochlear, supraorbital, auriculotemporal, and the occipital nerves has been used to treat a variety of headache disorders, suggesting a role for acupuncture and related techniques in neuromodulating these pathways noninvasively for similar headache relief and clinical benefit.

Compression of the supratrochlear nerve by a tense corrugator muscle, frontalis, or procerus muscle may also precipitate migraine, arguing for alleviation of this pressure through acupuncture, manual therapy, and/or laser therapy well before attempting surgical decompression with corrugator supercilii transection, botulinum toxin injection, or other invasive maneuvers.[5,6,7]

Stimulation of the supraorbital and supratrochlear nerves can aid patients with otherwise intractable trigeminal autonomic cephalalgias (TAC).[8] While implanted stimulators may work, why not try for relief with noninvasive neuromodulation first?

Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel and includes the midline GV channel) to the vertex.[9] Sensory dysfunctions associated with SON include hypoesthesia, paresthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, as well as migrainous features in some patients, depending on the extent of vascular involvement through trigeminosympathetic reflexes.

Syndromes similar to SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, and other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (i.e., at the supraorbital notch). Dry needling of BL 2, BL 7,

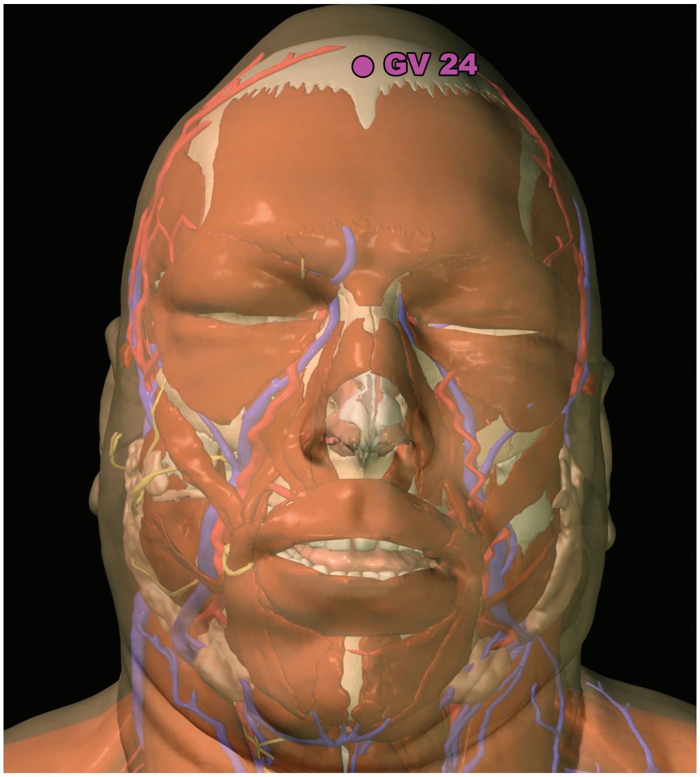

Figure 14-68. At certain times during the development of Chinese medical thought, some considered the original spirit to reside within the brain. As such, the forehead, as hallway, opens into the courtyard, or calvarium, that contains the brain or spirit.

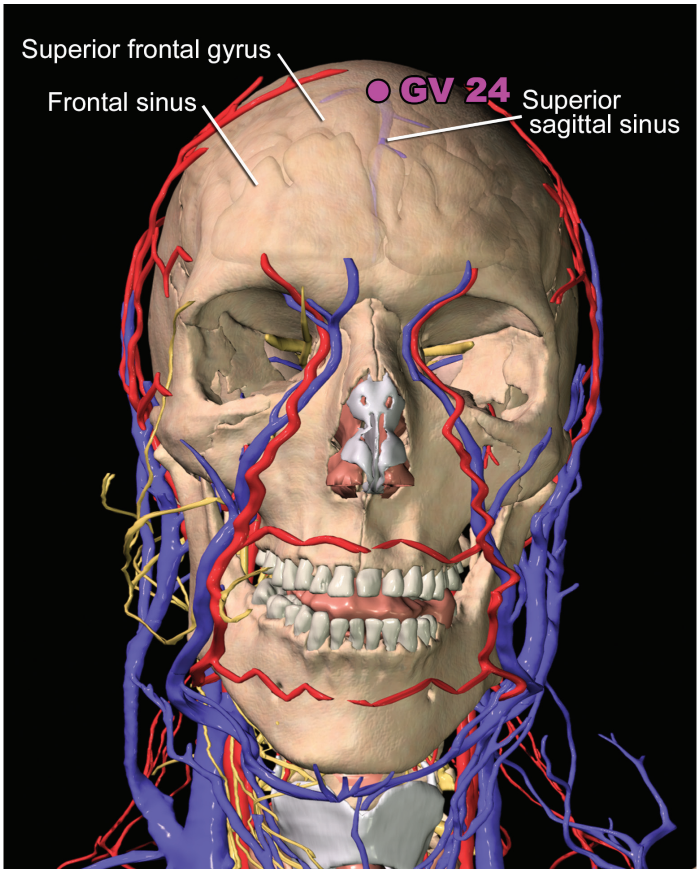

Figure 14-69. GV 24 sits close to the frontal sinuses of the skull, the superior sagittal venous dural sinus of the brain, and the superior frontal gyrus of the frontal lobe. Neural linkages from GV 24 to these sites open neuromodulatory opportunities of frontal sinus pain, sluggish venous outflow from the brain, and problems with executive control or inability to relax (i.e., the "cognitive flexibility" dimension of frontal lobe processing).

GV 23, GV 24, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

The prefrontal cortex, appearing at the rostral region of the frontal lobe in Figure 14-70, contributes to higher cognitive function and working memory. It also participates in executive function and spatially oriented processing.[10] Executive function allows an individual to control conflicting thoughts and desires that, if left unchecked, might lead to socially unacceptable outcomes. The lateral aspect of the superior frontal gyrus may be more important for the working memory network. This becomes relevant when neurosurgeons remove low-grade gliomas near the superior frontal gyrus. It also informs approaches involving laser therapy neuromodulation for brain injury. Laser therapy and other forms of neuromodulation may also improve local blood supply and venous drainage, supporting circulation and oxygen delivery to the superior frontal gyrus via GV 24 activation.

Meditation and exercise deregulate or down-regulate activity in the prefrontal cortex. In so doing, these processes invite altered states of consciousness known as "transient hypofrontality", considered a possible prerequisite for creativity.[11,12] Thus, neuromodulation at GV 23 and GV 24 may benefit the prefrontal cortex by increasing cognitive flexibility rather than by merely affecting its behavior in a unidirectional fashion (i.e., up or down).

Finally, while an acupuncture needle stimulating the surface at GV 24 would not directly impact cerebrospinal venous flow, reflexes mediated through the trigeminal nerve and the autonomic nervous system may indirectly influence venous outflow from the brain.

Vessels

- **Anastomosis between right and left supraorbital arteries:** The supraorbital arteries arise from the ophthalmic arteries and pass through the supraorbital foramina to supply the forehead and scalp.
- **Anastomosis between right and left supraorbital veins:** The supraorbital veins drain the rostral superficial scalp through the supraorbital and supratrochlear veins, which unite at the medial angle of the eye to form the angular vein. The angular vein becomes the facial vein at the inferior orbital margin.
- **Anastomosis between right and left supratrochlear arteries:** The supratrochlear arteries originate from the ophthalmic arteries and pass from the supraorbital margin to the scalp and the forehead.
- **Anastomosis between the right and left supratrochlear veins:** These veins begin on the forehead and scalp as a venous plexus and communicate with the superficial temporal veins and the supraorbital veins.
- **Emissary veins:** Emissary veins connect the dural venous sinuses to extracranial veins. Emissary veins lack valves, and blood may flow in either direction, though usually its flow is from the brain outward. Emissary veins vary in size and number.

Children have a frontal emissary vein that may persist in some adults. The frontal emissary vein connects the superior sagittal sinus with the frontal sinus and nasal cavities. Parietal emissary veins may occur in pairs, passing through the parietal foramina in the calvaria and allowing flow between the superior sagittal sinus and the veins of the scalp. Occipital or posterior auricular veins connect with the sigmoid sinus via the mastoid emissary veins, which course through the mastoid foramina.

Clinical Relevance: The superior sagittal sinus closely follows the course of the GV line as indicated in Figure 14-65. The connection between GV 24 and the superior sagittal sinus, as well as a lateral lacuna, shows well in Figure 14-70.

Embryologically, the superior sagittal sinus begins as two parallel structures that merge. The lateral lacunae that lie on either side of the sinus may represent remnants of the early double plexus. Their locations vary.

The lateral lakes in the adult brain receive blood from the cerebral veins. They also exhibit a carpet of arachnoid granulations that project into their floors and walls, allowing CSF to drain into them and thereby regulate intracranial pressure. Some lacunae receive so many granulations that they are practically filled with them.[13] While the largest and most consistently present lateral lacunae occur in the parietal and posterior frontal regions, lacunae such as the one appearing in Figure 14-70 can occur at more rostral areas.

Lacunae function as autoregulators of blood flow as they control

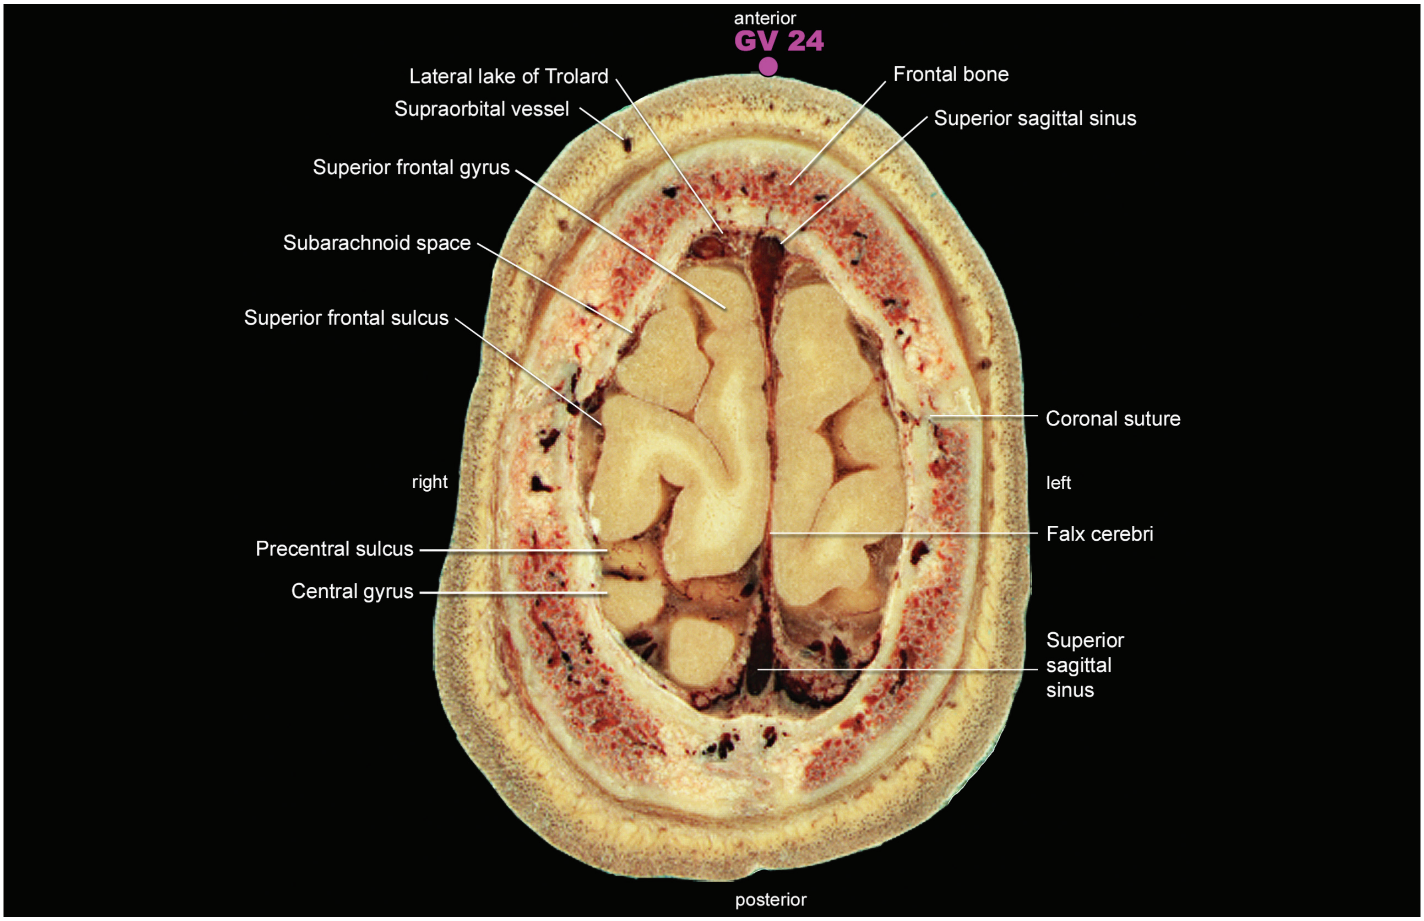

Figure 14-70. This cross-section shows the connection between a lateral lake of Trolard (a.k.a., lateral lacuna) and the superior sagittal sinus. In addition, it reveals the proximity of GV 24 to the superior frontal gyrus, a brain site involved in the conscious control over socially inappropriate impulses during activation and allowing creativity to manifest during de-activation (i.e., while meditating or exercising).

venous outflow resistance. Pathology within the lateral lacunae of the sagittal sinus compromises this draining activity. This may lead to brain swelling by reducing venous outflow. Lateral lacunae stenosis, which occurs in young women with endocrine disorders, can lead to benign intracranial hypertension.[14]

Arachnoid villi (or arachnoid granulations) are protrusions of the arachnoid layer of the meninges, through the dura mater, and into the venous sinuses of the brain. The arachnoid villi provide an exit route for cerebrospinal fluid (CSF) from the brain and into the venous system. The largest arachnoid villi occur along the superior sagittal venous sinus. Under normal circumstances, CSF draining from arachnoid villi keeps intracranial pressure from building.

Pain-sensitive fibers from the ophthalmic division of the trigeminal nerve supply sensation to the venous sinuses. These sinuses include the superior sagittal sinus, the meningeal arteries, and much of the supratentorial dura. Trigeminal fibers also supply the circle of Willis and other cerebral arteries as they join fibers from the sympathetic plexus. Trigeminal nerve irritation is central in the pathophysiology of head and facial pain.[15] Neuromodulation of trigeminal nerve function by dint of acupuncture and related techniques to rostral GV points over the calvarium may improve blood flow to and from the brain.

Supraorbital vessels anastomose with superficial temporal vasculature. Note in Figure 14-65 the proximity of a frontal branch of the superficial temporal artery to the supraorbital and supratrochlear nerves. Conceivably, myofascial restriction in the occipitofrontalis and fascial planes could compress the vessel and nearby nerves, leading to reduced tissue oxygenation and neural irritation. Given that pulsations in the occipital artery incite neuropathic pain in overlapping occipital nerves, perhaps, pulsations in the superficial temporal artery could aggravate supraorbital or supratrochlear neuralgia where the two intersect.

Indications and Potential Point Combinations

- **Frontal sinusitis:** GV 24, GV 24.5, GB 14, BL 2, Taiyang, LI 4.
- **Epistaxis:** GV 24, GV 21, LI 20, LI 4.
- **Rhinitis:** GV 24, LI 20, LI 4.
- **Frontal headache:** GV 24, GV 24.5, BL 2, GB 14, GB 20, local tender trigger points, LI 4 or LU 7.
- **Eye pain:** GV 24, BL 2, TH 23, GB 1, GB 20, ST 36.
- **Anosmia:** GV 24, GV 22, GV 24.5, LI 20, ST 3.
- **Anxiety:** GV 24, ST 36, HT 7, PC 6, CV 17, CV 14.

Evidence-Based Applications

- Acupressure at GV 24 and GV 24.5 produced **sedation** with similar electroencephalographic effects to general anesthesia.[1]

- Acupuncture at points such as GV 24, GV 20, GV 24.5, LI 4, LR 3, HT 7, and PC 6 benefited patients with **post-stroke anxiety** in a Chinese report.[2]
- Electroacupuncture between GV 24 and Yintang (GV 24.5) significantly **reduced the dose of sedation** requires for **critically ill patients on mechanical ventilation.**[16]
- Electroacupuncture applied to GV 24, GB 20, Sishencong, and GV 20 reduced signs and symptoms of earthquake-caused **posttraumatic stress disorder.**
- Electroacupuncture at GV 24, GV 20, Sish encong, and GB 20 improved the cognitive function of patients with **mild cognitive impairment** and outperformed nimodipine.[17]

GV 24.5

Yintang “Hall of Impression”

On the glabella, midway between the eyebrows.

Yin Tang is also known as “Ex-1” or “EX-HN3”. “EX-”refers to its designation as an “extra” point on the head and neck, or “HN”.

The location for GV 24.5 between GV 24 and GV 25 justifies its name but more acupuncturists recognize the term “Yintang”.

Muscles

- **Frontalis muscle (frontal belly of the occipitofrontalis, or epicranius, muscle):** The frontalis muscle originates on the epicranial aponeurosis and inserts onto the skin of the forehead and eyebrows. It elevates the eyebrow and wrinkles the forehead. Prolonged contraction of the frontalis muscle causes upper facial rhytides, i.e., forehead wrinkles.
- **Procerus muscle:** The procerus muscle is continuous with the frontalis muscle, extending from the forehead to the bridge of the nose. Allows squinting or frowning. Causes transverse furrows, or wrinkles, associated with “frown lines”. Note its position in Figure 14-71B.
- **Corrugator supercilii muscle:** Furrows the brow and contributes to the development of vertical “frown lines”. This small, narrow muscle sits at the medial end of the eyebrow, interposed between the frontalis and orbicularis muscles. Its fibers travel between the palpebral and orbital parts of the orbicularis oculi muscle. It protects the eyes from the glare of high sunlight by drawing the eyebrows mediad; this forms a roof over the medial canthi. The corrugator supercilii muscle has two heads – one transverse and one oblique. The oblique head works in conjunction with the depressor supercilii muscle and the medial head of the orbital portion of the orbicularis oculi muscle to depress the medial eyebrow; chronic contraction produces an oblique glabellar skin line. The zygomatic branch of the facial nerve supplies all three medial eyebrow depressor muscles.[8]
- **Depressor supercilii muscle:** Previously considered a part of the orbicularis oculi muscle, the depressor supercilii may be a distinct muscle that has a unique effect on movement of the eyebrow and skin over the glabella.[9] It originates on the medial orbital rim near the lacrimal bone and inserts on the medial orbit, inferior to the corrugator supercilii muscle. Some individuals have two heads and others only one.

Clinical Relevance: Myofascial pathology in the frontalis, procerus, and/or corrugator supercilii muscles can irritate the supratrochlear and supraorbital nerves. Dry needling of GV 24.5 may thereby reduce neuropathic pain and trigger point

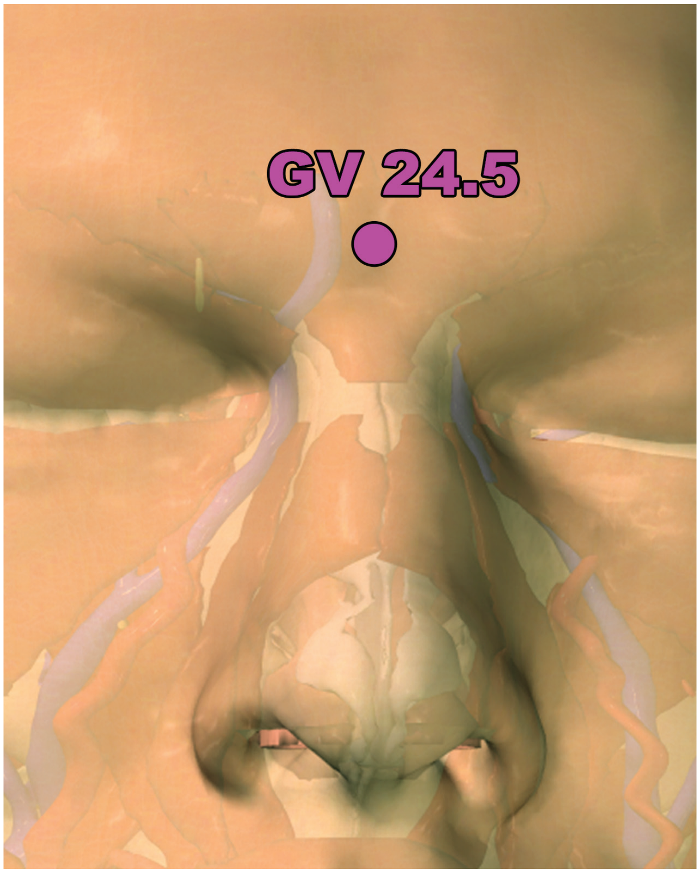

Figure 14-71A. GV 24.5, or Yintang, resides where Buddhists paint a red dot, symbolizing wisdom and illumination. Some cultures regard the “third eye” point as one that supports insight and intuition; hence the name “Hall of Impression”. Still others view Yintang as a doorway through which to influence the pituitary gland. Meditators turn their focus and their eyes toward this point and find this method of “inner gaze” relaxing.

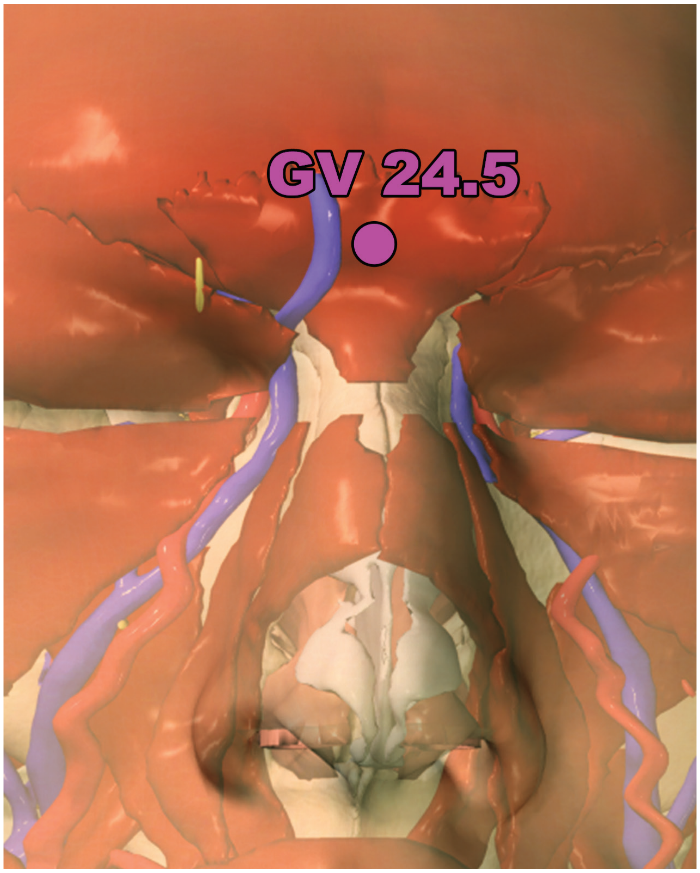

Figure 14-71B. This image reveals the presence of the procerus muscle at GV 24.5. Its prolonged contraction, in conjunction with the corrugator and depressor supercilii muscles, causes wrinkles at the glabella. Trigger points in these structures may entrap nerves, compress local vessels, and produce headache. Note the supratrochlear nerve and large ascending vein emerging from the medial end of this individual’s right orbicularis oculi muscle.

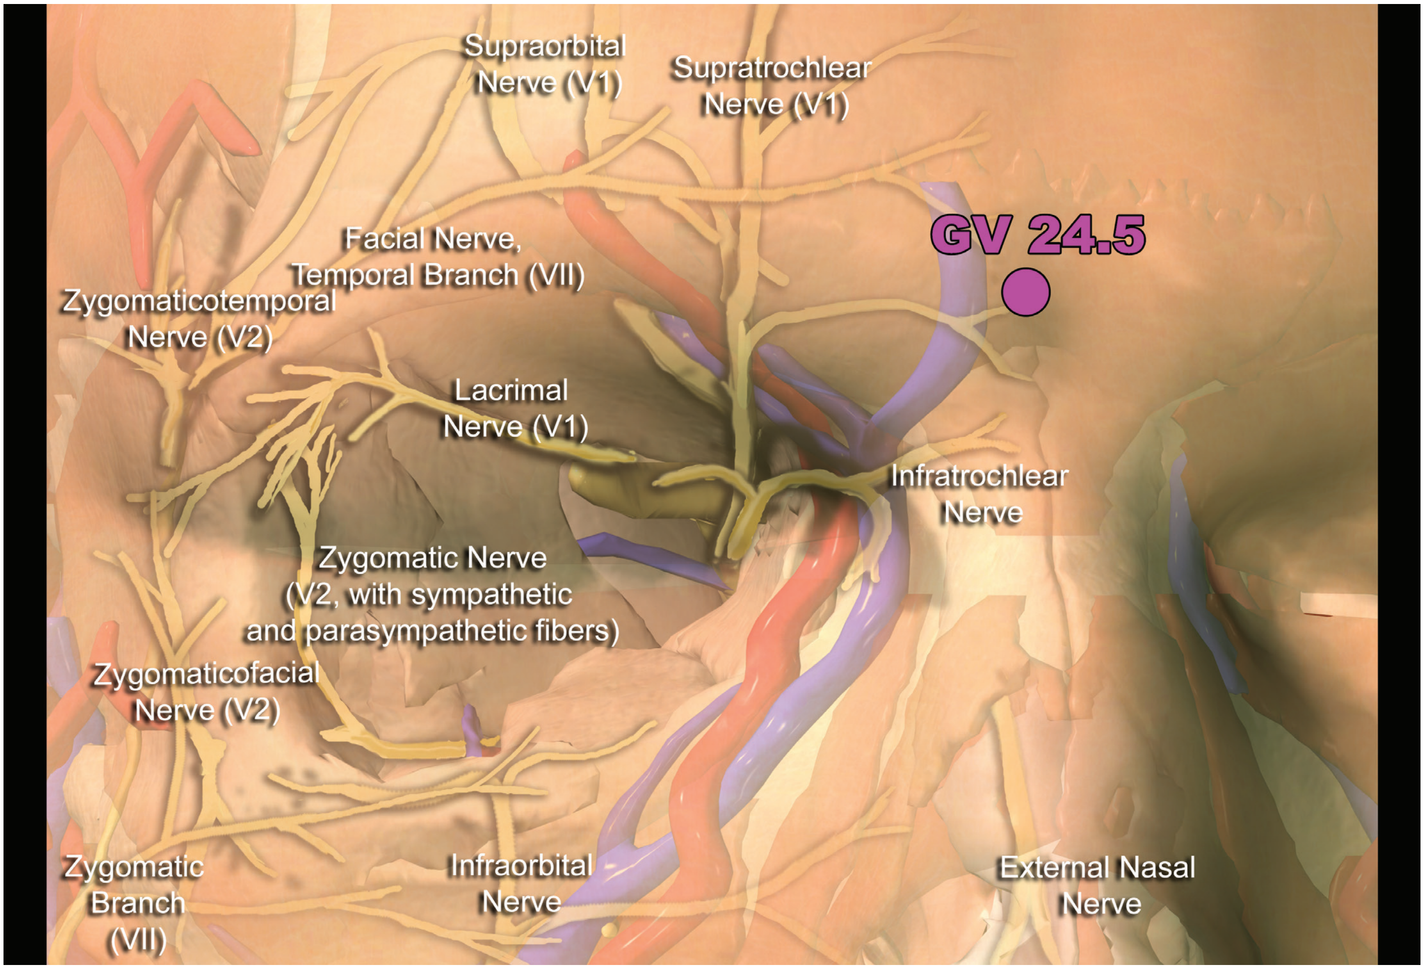

Supraorbital Nerve (V1)

Lacrimal Nerve (V1)
Infratrochlear Nerve
Zygomatic Nerve (V2, with sympathetic and parasympathetic fibers)
Zygomaticofacial Nerve (V2)
Zygomatic Branch (VII)
Infraorbital Nerve
External Nasal Nerve

Figure 14-71C. Numerous nerves directly supply the GV 24.5, as indicated here.

dysfunction. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

GV 24.5 represents one of the few points along the GV channel that interfaces with muscle tissue. With the ability to deactivate trigger points and stimulate mechanoreceptors for endogenous analgesia, acupuncture at GV 24.5 may deliver a bigger bolus of somatic afferent stimulation than other points that lack muscle tissue.

Both men and women may seek treatment for glabellar frown lines that cause a persistently angry appearance resulting from chronic contraction of the procerus and corrugator supercilii muscles. Botulinum injection of frown lines at the glabella causes reduction in procerus muscle volume lasting up to a year.[10] However, the depth of glabellar frown lines may returns to pre-treatment status well before that time, suggesting compensatory recovery of procerus function by agonist muscles and/or neuroplasticity. Furthermore, the dual innervation of the corrugator supercilii muscle by the buccal and zygomatic branches also complicates neurectomy.

Botulinum toxin type A injection into the glabella results in partial inactivation of the medial frontalis fibers. This leads to relatively increased muscle tone in the lateral and superior frontalis fibers, constituting a "brow lift"[11]

Nerves

- **Supratrochlear nerve (CN V_1):** The supratrochlear nerve is a branch of the frontal nerve that ascends medial to the supraorbital nerve and subsequently divides into two or more branches.

It provides skin sensation in the region extending from the mid-forehead to the area near the hairline.

- **Supraorbital nerve (CN V_1):** The supraorbital nerve is a continuation of the frontal nerve; it innervates the mucous membrane of the frontal sinus and the upper eyelid conjunctiva and provides sensation to the forehead skin and vertex.
- **Temporal branch of facial nerve (CN VII):** Innervates the frontalis muscle.
- **Angular nerve, formed by the buccal and zygomatic branches of facial nerve (CN VII):** Innervates the procerus muscle. The buccal branch receives fibers from the zygomatic branch and then forms the angular nerve.[12] It supplies the corrugator supercilii muscle.
- **Frontal, buccal, and zygomatic branches of the facial nerve (CN VII):** Innervate the corrugator supercilii muscle.

Clinical Relevance: Supraorbital/supratrochlear neuralgia, along with infraorbital neuralgia and ophthalmic division trigeminal neuralgia, comprise neuralgic etiologies of pain in the periorbital tissues and forehead.[13]

Dysfunction in the supratrochlear nerve may lead to migraine headache.[14] Peripheral nerve block of the supratrochlear, supraorbital, auriculotemporal, and the occipital nerves has been used to treat a variety of headache disorders, suggesting a role for acupuncture and related techniques in neuromodulating these

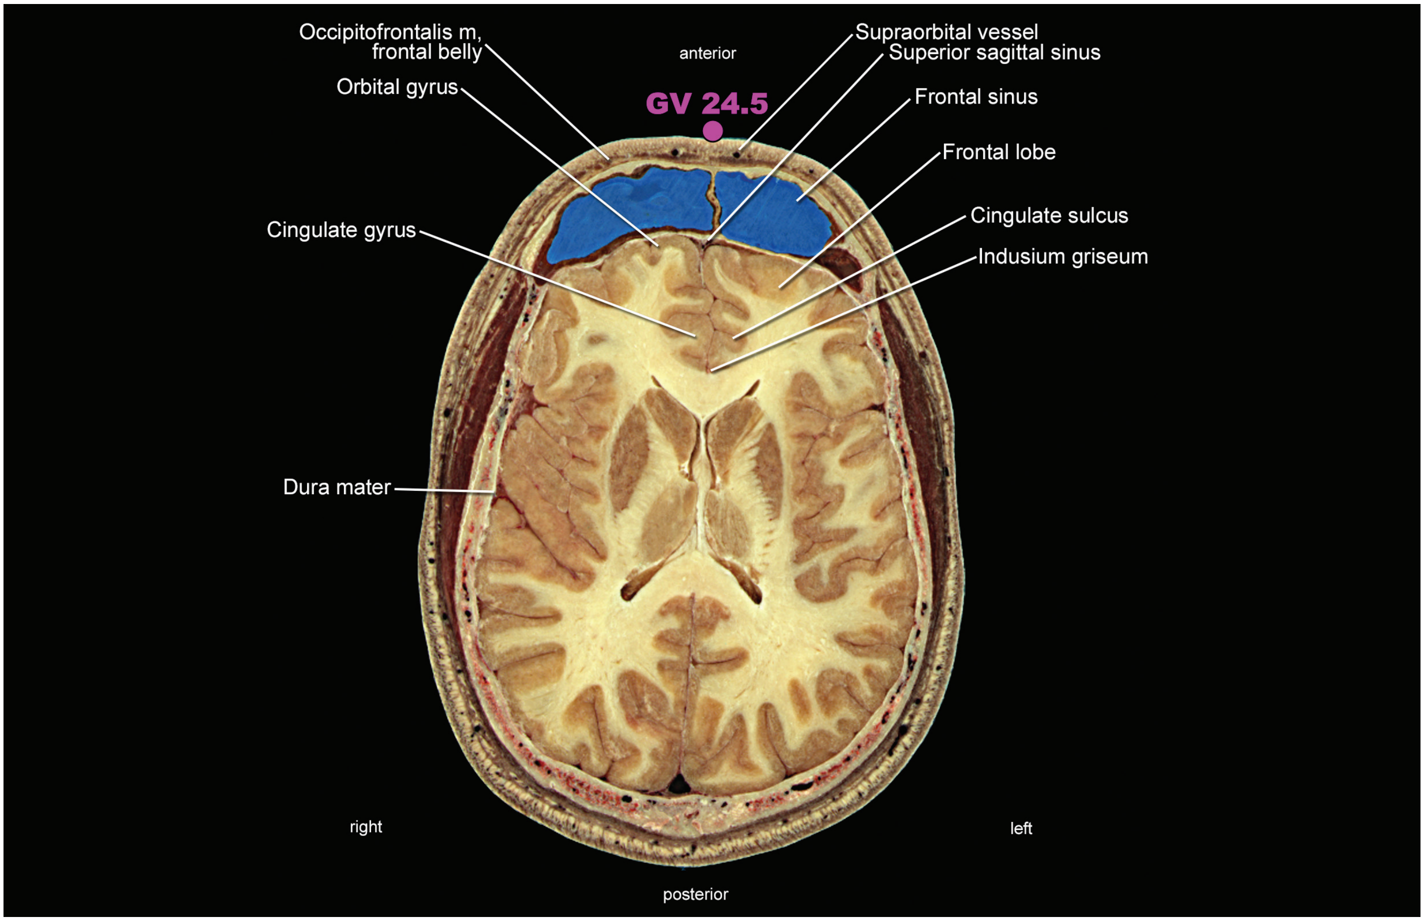

Figure 14-71D. A common indication for GV 24.5 is frontal sinus pain. The frontal sinuses appear here in blue, identifying air chambers within the skull. The proximity of the frontal lobe of the brain may help explain its benefits for mental agitation, emotional problems, and frontal lobe function.

pathways noninvasively for similar headache relief and clinical benefit.

Compression of the supratrochlear nerve by a tense corrugator muscle, frontalis, or procerus muscle may also precipitate migraine, arguing for alleviation of this pressure through acupuncture, manual therapy, and/or laser therapy well before attempting surgical decompression with corrugator supercilii transection, botulinum toxin injection, or other invasive maneuvers.[15,16,17]

Stimulation through implanted devices of the supraorbital and supratrochlear nerves can aid patients with otherwise intractable trigeminal autonomic cephalalgias (TAC).[18] It seems clear that one might try for relief with noninvasive neuromodulation first with acupuncture, laser therapy (including mandatory eyewear and cautious application of laser to GV 24.5), and myofascial release or massage.

Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel and includes the midline GV channel) to the vertex.[19] Sensory dysfunctions associated with SON include hypoesthesia, paresthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, as well as migrainous features in some patients, depending on the extent of vascular involvement through trigeminosympathetic reflexes.

Syndromes similar to SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, and other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (i.e., at the supraorbital notch).

The prefrontal cortex, appearing at the rostral region of the frontal lobe in Figure 14-71D, contributes to higher cognitive function and working memory. It also participates in executive function and spatially oriented processing.[20] Executive function allows an individual to control conflicting thoughts and desires that, if left unchecked, might lead to socially unacceptable outcomes. The lateral aspect of the superior frontal gyrus may be more important for the working memory network. This becomes relevant when neurosurgeons remove low-grade gliomas near the superior frontal gyrus. It also informs approaches involving laser therapy neuromodulation for brain injury.

Meditation and exercise deregulate or down-regulate activity in the prefrontal cortex. In so doing, these processes invite altered states of consciousness known as “transient hypofrontality”, considered a possible prerequisite for creativity.[21,22] Thus, neuromodulation at GV 24.5 may benefit the prefrontal cortex by increasing cognitive flexibility rather than by merely affecting its behavior in a unidirectional fashion (i.e., up or down).

In contrast to “meditating on the third eye” at GV 24.5 (see Figure 14-71A), tapping on this site causes a “glabellar reflex”.

The ophthalmic division of the trigeminal nerve mediates the afferent limb. Three electrophysiologically distinct responses reflect activation of the cortex and basal ganglia.[23] As such, some consider its presence as an indicator of Parkinson's disease, although it has also been called a "primitive reflex". The trigeminal nerve afferent signal reflexes with the orbicularis oculi muscle to cause a blink reflex. When the blinking persists, this suggests neurologic dysfunction, possibly signaling "frontal release", i.e., the appearance of primitive reflexes in cases of frontal lobe lesion(s).

Research shows that acupressure at this site calms parents whose children are about to undergo elective surgery,[24] implicating that neuromodulation follows via trigeminovagal connections or frontal lobe effects.

Prolonged contraction of the procerus muscle follows excessive stimulation of the buccal branch of the facial nerve. This contributes to frown lines near the nasal bridge.[25] Plastic or cosmetic surgeons seeking to block or eliminate[26] nerve function sometimes find that their attempts alleviate glabellar frown lines fail. Partly, the emotional state (i.e., anger, worry, or stress) that incites the facial nerve often remains. In addition, several muscles contribute to the onset and maintenance of frown lines, including the corrugator supercilii, depressor supercilii, and procerus muscles. The corrugator supercilii receives nerve supply not only from the buccal branch but also the frontal and zygomatic facial nerve branches.[27] Resolution of frown lines may defy attempts at denervation until all neural participation has been reduced. That said, neuromodulation and trigger point deactivation with acupuncture and related techniques at GV 24.5 may reduce frown lines while leaving anatomy intact.

In a way resembling the putative effects of botulinum toxin type A,[28] acupuncture and related techniques may facilitate motor repatterning and interrupt the sustained muscle contraction that leads to wrinkles.

Vessels

- **Anastomosis between right and left supratrochlear arteries:** The supratrochlear arteries originate from the ophthalmic arteries and pass from the supraorbital margin to the scalp and the forehead. They supply the glabella at GV 24.5. After leaving the ophthalmic artery inside the orbit, each supratrochlear artery emerges by piercing the orbital septum above the medial canthus (BL 1). On its way to the forehead, each supratrochlear artery then courses along the procerus and corrugator supercilii muscles at the root of the nose. They then pass to the forehead subcutaneously.[29] The supratrochlear and supraorbital arteries anastomose ipsilaterally. The right and left supratrochlear arteries also anastomose across the midline. The supratrochlear arteries do not follow the supratrochlear veins, unlike most arteries that parallel companion veins. The supratrochlear arteries exhibit a minute reticular venous network attending to their adventitia. These vasa vasorum connect to the polygonal venous network of the forehead along with a few small ascending veins that drain the dermis.
- **Anastomosis between the right and left supratrochlear veins:** The supratrochlear veins begin on the forehead and scalp as a venous plexus (the polygonal venous network"); they communicate with the superficial temporal veins as well as the supraorbital veins.
- **Large ascending veins:** Large ascending veins (usually one on each side of the midline) arise in the vicinity of the medial canthus, either from the angular vein or the transverse nasal vein. They pierce the procerus muscle and pass beneath the dermis of the forehead. They may meet at GV 24.5 or ascend as parallel structures toward the vertex.
- **Deep glabellar venous network:** The deep venous drainage system in the glabellar region comprises a network that includes the superior transverse orbital vein, angular vein, facial vein, and root of the transverse nasal vein, all deep to the orbicularis oculi muscle.
- **Emissary vein at the foramen cecum:** The foramen cecum in the frontal bone transmits the emissary vein from the nose to the superior sagittal sinus. This creates a conduit by which bacteria from the nose and face can course into the cranium and infect the meninges and brain. The frontal diploic vein, draining the frontal sinus and frontal diploe in some species, connects to the rostral extent of the superior sagittal sinus.
- **Cavernous sinus connections:** The cavernous sinuses are part of the dural sinus system and reside on either side of the sella turcica (which houses the pituitary gland), lateral and superior to the sphenoid sinus and immediately posterior, or dorsal, to the optic chiasm.[30] A largely valveless venous web drains blood into the cavernous sinuses from the facial vein (by way of the superior and inferior ophthalmic veins) as well as the middle cerebral and sphenoid veins. Other venous structures linked to the network include the inferior petrosal sinuses, the internal jugular veins, the sigmoid sinuses and superior petrosal sinuses.

Clinical Relevance: While an acupuncture needle stimulating the surface at GV 24.5 would not directly impact cerebrospinal venous flow, reflexes mediated through the ophthalmic division of the trigeminal nerve and the autonomic nervous system may indirectly influence venous outflow from the brain.

Glabellar skin receives arterial supply mainly from the supratrochlear arteries, as noted above. Venous blood exodus from the glabella and forehead does not parallel arterial networks and is less well characterized. Surgical complications from plastic surgery or nasal reconstruction may occur if surgeons lack understanding of the unique nature of venous drainage from the glabella and forehead. These complications include venous congestion, partial flap necrosis, and contour irregularities. Because veins of the forehead may lie at some distance from major arteries, island flaps may undergo engorgement due to good inflow but insufficient outflow, should the narrow arterial pedicle exclude venous access.

The "danger triangle" of the face refers to sites on the face from which infection may spread to the cavernous sinuses, i.e., deep internal sections of the dural venous sinus network. The complexity of the intracranial venous channels and its bidirectional flow facilitate the spread of infection from the nose, tonsils, and eyes into the cavernous sinuses, deep inside the cranium.

Cavernous sinus thrombosis typically occurs as a late complication of infection affecting the central portion of the face (in the danger triangle) or paranasal sinuses. Maxillary tooth or otic infection, bacteremia, and trauma can also cause cavernous sinus thrombosis. Without appropriate antimicrobial agents, intracranial septic thrombosis of the cavernous sinus may produce devastating complications due to the myriad neurovascular connections made in the sinuses. The internal carotid artery courses within the cavernous sinuses along with the sympathetic plexus that surrounds it. Cranial nerves supplying extraocular muscles, i.e., CN III, IV, and VI, follow its lateral walls. Trigeminal nerves from the ophthalmic and maxillary divisions travel within the walls.

Consequences of cavernous sinus thrombosis thus include cranial nerve deficits and visual impairment (due to increased intraocular pressure and traction on both the optic nerve and central retinal artery). Delaying the diagnosis of cavernous sinus thrombosis and its treatment by surgical drainage and antibiotics may prove fatal.

While early signs may be nonspecific, any patient that presents with 1) a sharp, progressive headache in the ophthalmic and/or maxillary trigeminal regions and 2) abnormal cranial nerve findings (affecting CN III, IV, V_1, V_2, and/or VI) should receive evaluation for cavernous sinus thrombosis. Headache typically precedes cranial nerve dysfunction and the periorbital edema that reflects venous obstruction. Dural irritation can cause nuchal rigidity and Kernig or Brudzinski signs. Increased retrobulbar pressure can lead to exophthalmos and ophthalmoplegia. Eye swelling that begins as a unilateral event and becomes bilateral within one to two days has been considered "pathognomonic" of cavernous sinus thrombosis.[31] Fever may follow or occur at any point in the process. Patients ordinarily report history of sinusitis or manipulation of a mid-face furuncle over the past five to ten days. Some have had recent surgery of the "danger zone" or maxillary teeth. Once mental status changes manifest, as in confusion, drowsiness, or coma, death may soon follow, as this sign indicates that the infection is impairing brain function. It may then spread systemically and cause sepsis. As many as 30% of patients with cavernous sinus thrombosis die; survivors suffer permanent neurologic sequelae.

Indications and Potential Point Combinations

- **Frontal headaches:** GV 24.5, GB 14, BL 3, BL 4, BL 9, BL 10, GB 21, pertinent trigger points.
- **Insomnia:** GV 24.5, HT 7, GV 20, LR 3.
- **Nasal pain:** GV 24.5, GV 25, ST 3.
- **Anosmia:** GV 24.5, LI 20, BL 2.
- **Frontal sinusitis:** GV 24.5, GV 23, LI 4, ST 43, ST 44.
- **Rhinitis:** GV 24.5, LI 20, LI 4.
- **"Frown lines" due to chronic contraction of the procerus and corrugator/depressor supercilii muscles:** GV 24.5, BL 2, BL 1, GB 14, TH 23, HT 7.

Evidence-Based Applications

- Electroacupuncture at GV 20, GV 24.5, and either (GB 34 + SP 6), (PC 6 + SP 6), or (KI 3 + SP 6) – depending on the type of **depression** – treated depression as effectively as tricyclic antidepressant medication.[1]
- A Chinese trial looking at the effect of LI 4, LR 3, GV 20, and GV 24.5 showed improved **"depressive neurosis"** comparable to Prozac.[2]
- Treatment of Yintang, GV 20, GV 16, GV 14, GB 20, PC 6, and SP 6 accelerated the clinical response to the selective serotonin reuptake inhibitor paroxetine, prevented the worsening of **depression**, and provided, through electroacupuncture of these sites, long-lasting enhancement of the drug's antidepressant effects.[32]
- Acupressure applied to Yintang by parents whose children were scheduled to undergo elective surgery yielded statistically significant reductions in **anxiety** experienced by these parents compared to a "sham" point near TH 23.[3]
- Electroacupuncture between GV 24 and Yintang (GV 24.5) significantly **reduced the dose of sedation** required for **critically ill patients on mechanical ventilation,** thereby decreasing **anxiety.**[33]
- Acupuncture at Yintang significantly reduced **preoperative anxiety** in adult surgical patients. *J Altern Complement Med.* 2013;19(5):420-424.
- Acupuncture at GV 24.5, KI 3, LR 3, SP 9, LI 4, HT 7, ST 36, and SP 9 reduced systolic and diastolic pressure in persons with **essential hypertension.** Nitric oxide concentration increased significantly as well.[34]
- Electroacupuncture at Yintang and GV 20 produced a series of changes in activation of the frontal lobe, cingulate gyrus, and cerebellum, reinforcing its value for inducing changes in **brain function.**[35]
- Acupuncture at Yintang, PC 6, and CV 4 led to a **reduction in heart rate** and "state of health".[36]
- EA at GV 2, GV 14, GV 20, GV 24.5, prevented tissue shrinkage of the dorsal hippocampus, basolateral nucleus of the amygdala, substantia nigra, and perirhinal cortex. EA at ST 36 and SP 6 prevented tissue shrinkage in all of the aforementioned regions except for the dorsal hippocampus. EA to GV 2 + GV 14 + GV 20 + GV 24.5 or ST 36 +SP 6 reduced the cognitive deficits in pilocarpine-epileptic rats. Administration of p-chlorophenylalanine, a compound that depletes serotonin, negated the behavioral and some of the histologic changes due to EA. This suggests that the functional recovery exhibited by the rats may have been influenced through serotonergic pathways affected by acupuncture and subsequent **neuroprotective benefits.**[4]
- Acupressure at GV 24 and GV 24.5 produced **sedation** with similar electroencephalographic effects to general anesthesia.[5]
- Electroacupuncture applied to Yintang (GV 24.5), GV 20, Sishencong (GV 20 plus four points 1 cun away in four directions), and Anmian ("Peaceful Sleep", located midway between TH 17 and GB 20) produced better results over placebo acupuncture for the short-term treatment of primary **insomnia** in a Chinese report.[6]
- Acupuncture at LI 4, LI 20, and Yintang demonstrated measurable improvement in nasal airflow compared to control points in patients suffering from **chronic nasal congestion.**[7]

GV 25

Su Liao “White Crevice”
“White Bone-Hole”

At the tip of the nose on the midline.

Cartilage

- **Alar cartilage, medial crus (lower part of the cartilaginous wall of the nasal septum):** Forms part of the cartilaginous portion of the nose.

Clinical Relevance: The tip of the nose is often a site of focus for plastic surgeons. For example, revision rhinoplasty for cleft nasal deformity presents numerous challenges given the extent of tissue abnormalities affected.[1] “Smiling deformity” or rhinogingivolabial syndrome is a condition in which the tip of the nose appears to lengthen during smiling or talking as a result of excessive depressor septi nasi muscle contraction.[2,3] An overactive the depressor muscle can make the upper lip seem shortened and reveal an unattractive amount of maxillary gingival tissue.[4,5] A surgical treatment for this problem involves septoplasty (to correct the septum if deviated), dynamic rhinoplasty (i.e., muscular treatment of the nasal tip and upper lip), rhinosculpture (addressing aesthetics of the nasal root, dorsum, and tip), and turbinectomy (involving partial bone-mucous resection in cases of hypertrophied turbinates). Botulinum toxin obviates the need for surgery when injected into the depressor septi nasi muscle.[6] Conceivably, release of tension in the depressor muscle through acupuncture and related techniques could also improve appearance.

A firm to hard lump at the tip of the nose may represent a chondroma of the nasal tip.[7]

Nerves

- **External nasal branch of the anterior ethmoidal nerve (CN V$_1$):** Supplies the tip of the nose.

Clinical Relevance: Rhinoplasty may impair sensation at the tip of the nose, a frequent focus for cosmetic improvement.[8] The external nasal nerve supplies the nasal tip and adjacent upper columella; subcutaneous dissection during rhinoplasty may injure the nerve where it passes between the nasal bone and upper lateral cartilage. The external nasal nerve may also suffer injury during intercartilaginous and cartilaginous splitting incisions that occur during endonasal rhinoplasty.

Neuromodulation by means of acupuncture and related techniques applied to GV 25 may accelerate return of sensation to the tip of the nose.

“Nasal migraine” may stem from heminasal pain mediated by trigeminal afferents from the ophthalmic, maxillary or mandibular divisions.[9] In certain individuals, sneezing heralds onset of nasal migraine. In others, pressure at the tip of the nose at GV 25 may trigger the migraine-tic syndrome. Differential diagnoses include post-traumatic nasal pain, mucosal contact point headache, rhinosinusitis, nasociliary neuralgia, persistent idiopathic facial pain, and idiopathic rhinalgia. Treatment with acupuncture, manual therapy, and/or laser therapy at GV 25 and nearby regions may reduce neuropathic irritability of trigeminal afferents.

Vessels

- **Dorsal nasal artery:** Branches off of the ophthalmic artery to supply the dorsal surface of the nose.
- **Lateral nasal artery:** Branches from the facial artery. Anastomoses with other arterial branches of the facial artery, including the septal and alar arteries. Also anastomoses with the dorsal nasal artery (from the ophthalmic artery) and the infraorbital branch of the internal maxillary artery.

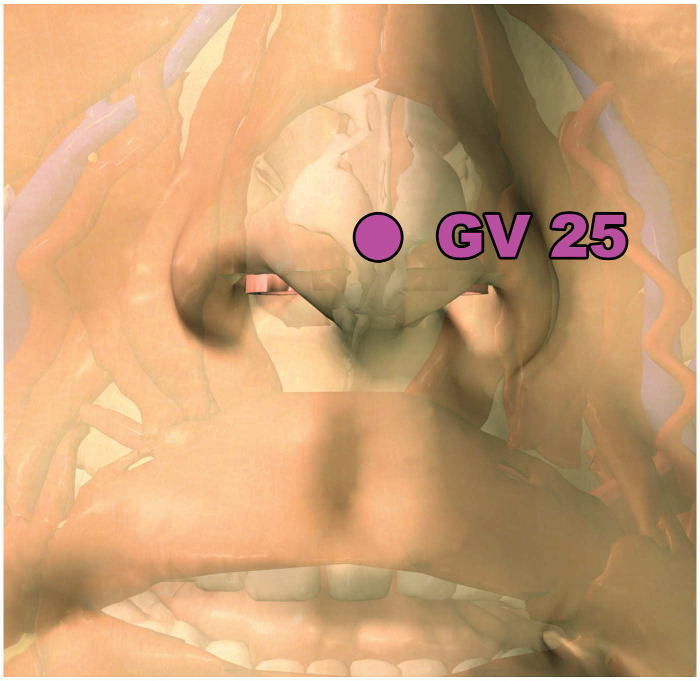

Figure 14-72. A dip at the tip of the nose designates the location of GV 25.

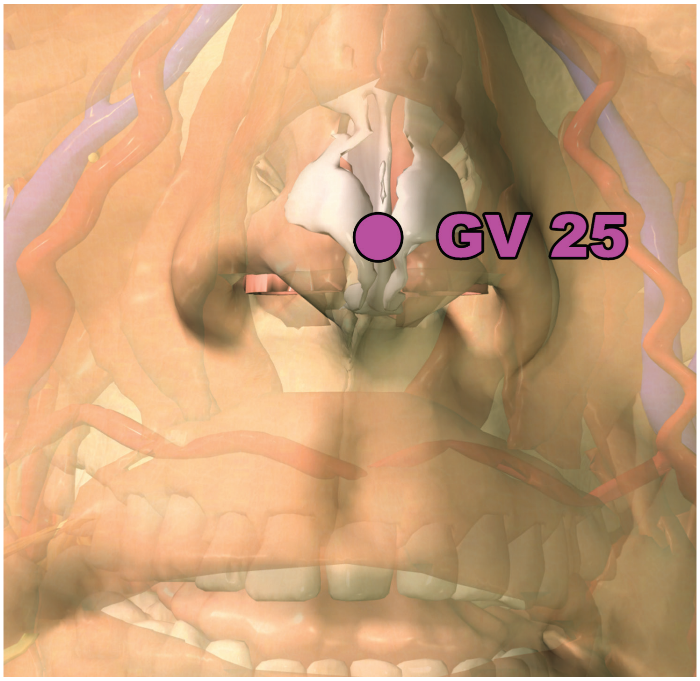

Figure 14-73. The cleft in the nasal cartilage at GV 25 reveals the reason for its descriptive names, “White Crevice” and “White Bone-Hole”.

Figure 14-74. This cross section shows the relationship between the nasal septal cartilage, the bright white structure, and GV 25.

Clinical Relevance: The nasal tip receives its main source of blood supply from the lateral nasal artery in over three-quarters of individuals.[10] The dorsal nasal artery serves as the main arterial supply to the nose in the remaining approximate one-quarter of the population.

Indications and Potential Point Combinations

- **Rhinitis:** GV 25, GV 24.5, LI 20.
- **Sinusitis:** GV 25, GV 24.5, GV 23, add BL 2 and GB 14 for frontal sinusitis or ST 3 and LI 20 for maxillary sinusitis.
- **Nasal migraine:** GV 25, local laser and myofascial release. Consider cranial manipulation and acupuncture as indicated and where needed.

GV 26

Shui Gou “Water Trough” or Ren Zhong “Man’s Middle”

On the philtrum, on the anterior midline, at the junction of the upper third and lower two-thirds of the distance from the nose to the margin of the upper lip.

Muscles

- **Orbicularis oris muscle:** Serves as the first in the series of sphincters associated with digestive structures. Orbicularis oris muscle fibers encircle the mouth and reside within the lips. Active contraction causes the lips to pucker, although over time its effects on the skin may show as wrinkles. The orbicularis oris muscle has been regarded as a simple sphincter, or circular muscle, like the orbicularis oculi. Now, some claim that it comprises four independent quadrants of muscles that together encircle the mouth. Orbicularis oris fibers intermix with those of surrounding muscles of facial expression that also insert onto the lips, such as the buccinator muscle. Additional intermingling muscles include the caninus, triangularis, quadratus labii superioris, zygomaticus, and quadratus labii inferioris, along with the nasolabilis, incisivus labii superioris, mentalis, and incisivus labii inferioris muscles.
- **Depressor septi nasi muscle:** Constricts the nasal aperture via the nares by drawing the nasal septum downward. Fibers arise from the incisive fossa of the maxilla and insert onto the nasal septum and dorsal portion of the alar part of the nasalis muscle. Sits between the mucous membrane of the lip and the orbicularis oris. As such, one can better access the depressor muscle through an intraoral approach, in the vicinity of GV 28.

Clinical Relevance: “Smiling deformity” or rhinogingivolabial syndrome is a condition in which the tip of the nose appears to lengthen during smiling or talking as a result of excessive depressor septi nasi muscle contraction.[32,33] An overactive the depressor muscle can make the upper lip seem shortened and reveal an unattractive amount of maxillary gingival tissue.[34,35] A surgical treatment for this problem involves septoplasty (to correct the septum if deviated), dynamic rhinoplasty (i.e., muscular treatment of the nasal tip and upper lip), rhinosculpture (addressing aesthetics of the nasal root, dorsum, and tip), and turbinectomy (involving partial bone-mucous resection in cases of hypertrophied turbinates). Botulinum toxin obviates the need for surgery when injected into the depressor septi nasi muscle.[36] Conceivably, release of tension in the depressor muscle through acupuncture and related techniques at GV 26 could also improve appearance and allow the upper lip to lengthen.

In contrast to the short lip syndrome just described, the aging perioral region is associated with upper lip lengthening.[37] The orbicularis oris muscle thins, the subcutis thickens and elastic as well as collagen fibers degenerate. Conceivably, treatment with laser therapy or other means of improving tissue health may forestall some of the consequences of advancing age on perioral appearance.

Nerves

- **Superior labial branches of infraorbital nerve (CN V_2):** Provides cutaneous sensation to the upper lip.
- **Buccal branches of facial nerve (CN VII):** The buccal branch of the facial nerve supplies the upper part of the orbicularis oris muscle and the inferior portion of the levator labii superioris muscle.
- **Sympathetic input:** Tissues associated with GV 26 receive sympathetic fibers from the cervical sympathetic ganglia (T1-T5). Trigeminal nerve branches provide sensation to the skin and underlying structures. Somatosensory-sympathetic and somatosensory-parasympathetic fiber combinations occur in blood vessels of the face.[1]

Clinical Relevance: Close connections between somatosensory and autonomic fibers help regulate regional microcirculation. These communications may also mediate autonomic responses to afferent stimulation. Acupuncture at GV 26 strongly activates the sympathetic nervous system, manifested as elevated catecholamine levels that increase cardiac output and boost stroke volume.

Stimulation of extracranial trigeminal nerve fibers can also increase cortical cerebral blood flow.[2] Electrical stimulation at 2 Hz delivered to sympathetic fibers of the nose cause strong sympathetic activation and vasoconstriction of nasal mucosa.[3] Two Hz electroacupuncture stimulation approximates the frequency of pecking during resuscitation maneuvers. These neurophysiologic responses explain how acupuncture at GV 26 reverses cardiopulmonary collapse and loss of consciousness.

GV 26 also assists in the recovery of orbicularis oris muscle function in the event of facial nerve paralysis affecting its buccal branch. However, tenderness to needling here may warrant selection of other points such as ST 4 and TH 17.

Chronic pursing of the lips may worsen wrinkles on the upper lip. For this condition, plastic surgeons seek to interrupt, rather than improve, facial nerve function in order to reduce muscle contraction and foster skin relaxation.[38]

Vessels

- **Anastomosis of the superior labial arteries:** The superior labial arteries branch from the facial artery and course mediad along the upper lip, anastomosing at GV 26. They supply the upper lip, nasal septum, and nasal alae. See Figure 14-75 B to view the relationship between the facial artery and the superior labial arteries.

Clinical Relevance: Knowledge of the arterial anatomy of the oronasal region is imperative for cosmetic and lip repair surgery.[39] It also aids in revealing the clinical significance of GV 26 for cardiopulmonary resuscitation by dint of its local and abundant sympathetic supply associated with the perioral vascular network.

Indications and Potential Point Combinations

- **Vasovagal syncope, loss of consciousness, cardiopulmonary arrest:** Vigorous pecking applied to GV 26 until resistance is felt at the bone or cartilage.

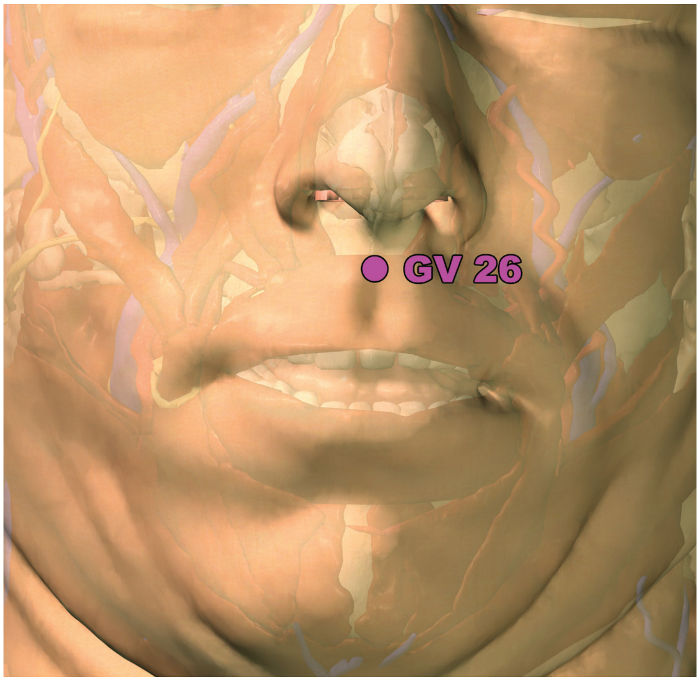

Figure 14-75A. The canal between the nasal planum and upper lip, i.e., the philtrum, looked like a "Water Trough" to the ancient Chinese, along which discharge from the nose might gather.

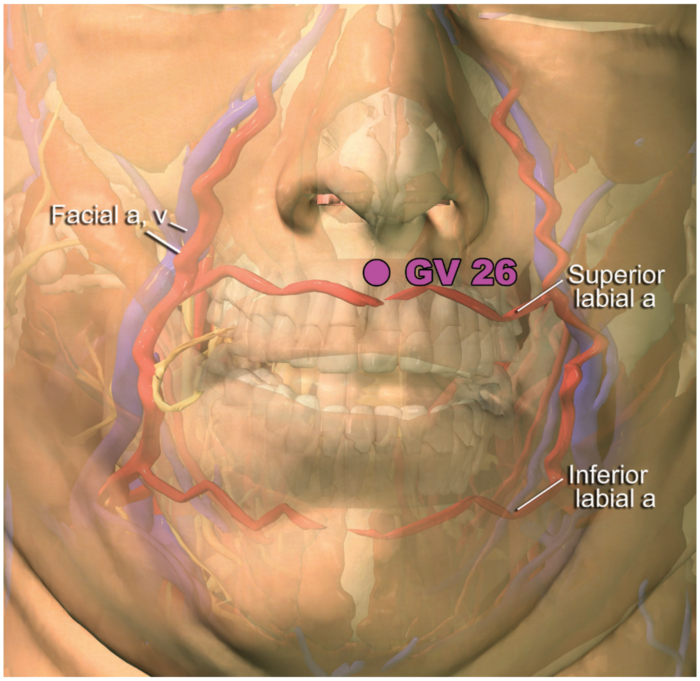

Figure 14-75B. Sympathetic innervation of oronasal vasculature accounts for the strong effects GV 26 has on the cardiopulmonary system and the brain. This image reveals the branching of the superior and inferior labial arteries from the facial artery.

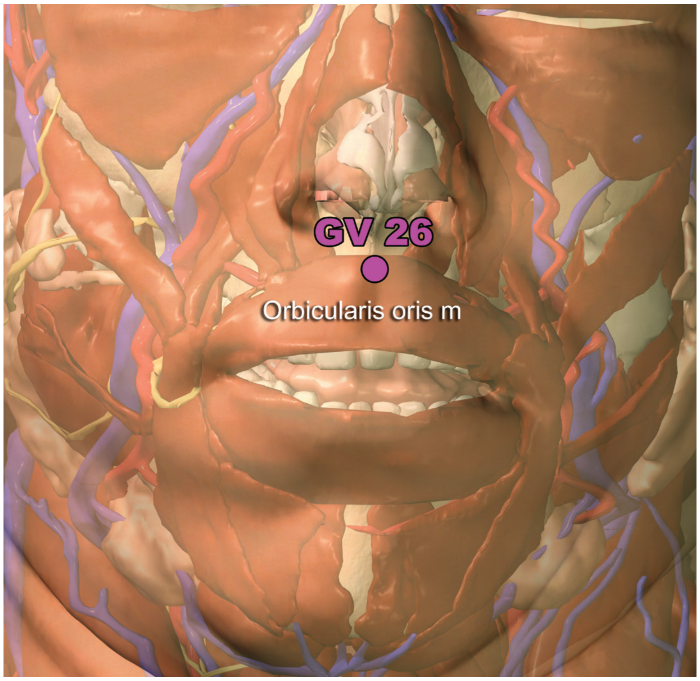

Figure 14-75C. Hypofunction of the orbicularis oris muscle, as in cases of facial nerve injury, may allow food to fall out of the mouth during mastication. Treatment of GV 26, ST 4, and CV 24 by acupuncture and related techniques may help restore function of the orbicularis oris by activating facial nerve branches that supply motor innervation to the muscle.

- **Acute lumbar or cervical spasm or pain:** GV 26 needling while the patient moves about and tries to increase range of motion of the spine.
- **Shock, coma:** GV 26, PC 6, KI 1, ST 36.
- **Sunstroke:** GV 26, KI 1, GV 20.
- **Facial edema:** GV 26, ST 9, LI 17.
- **Facial nerve paralysis affecting the buccal branch:** GV 26, TH 17, ST 4, LI 19.

Evidence-Based Applications

- **Cardiopulmonary resuscitation:**[1,2] Tissues associated with GV 26 receive sympathetic fibers from the cervical sympathetic ganglia. Trigeminal nerve branches provide sensation to the skin and underlying structures. Sensory-sympathetic and sensory-parasympathetic fiber combinations inhabit the blood vessels of the face.[4] Intimate interconnections between sensory and autonomic fibers regulate microcirculation; they may also mediate the autonomic responses to afferent stimulation provided by acupuncture. Acupuncture at GV 26 activates the sympathetic nervous system. This elevates catecholamine levels, increases cardiac output and stroke volume. Stimulation of extracranial trigeminal nerve fibers can increase cortical cerebral blood flow.[5]

Electrical stimulation at 2 Hz delivered to sympathetic fibers of the nose can cause vigorous sympathetic activation, exhibited as strong vasoconstriction of nasal musosal blood vessels.[6] Two cycles of stimulation per second (i.e., 2 Hz) approximates the frequency of pecking GV 26 during resuscitation maneuvers. Combined, these neurophysiologic responses help explain GV 26's role in reversing cardiorespiratory collapse and loss of consciousness.

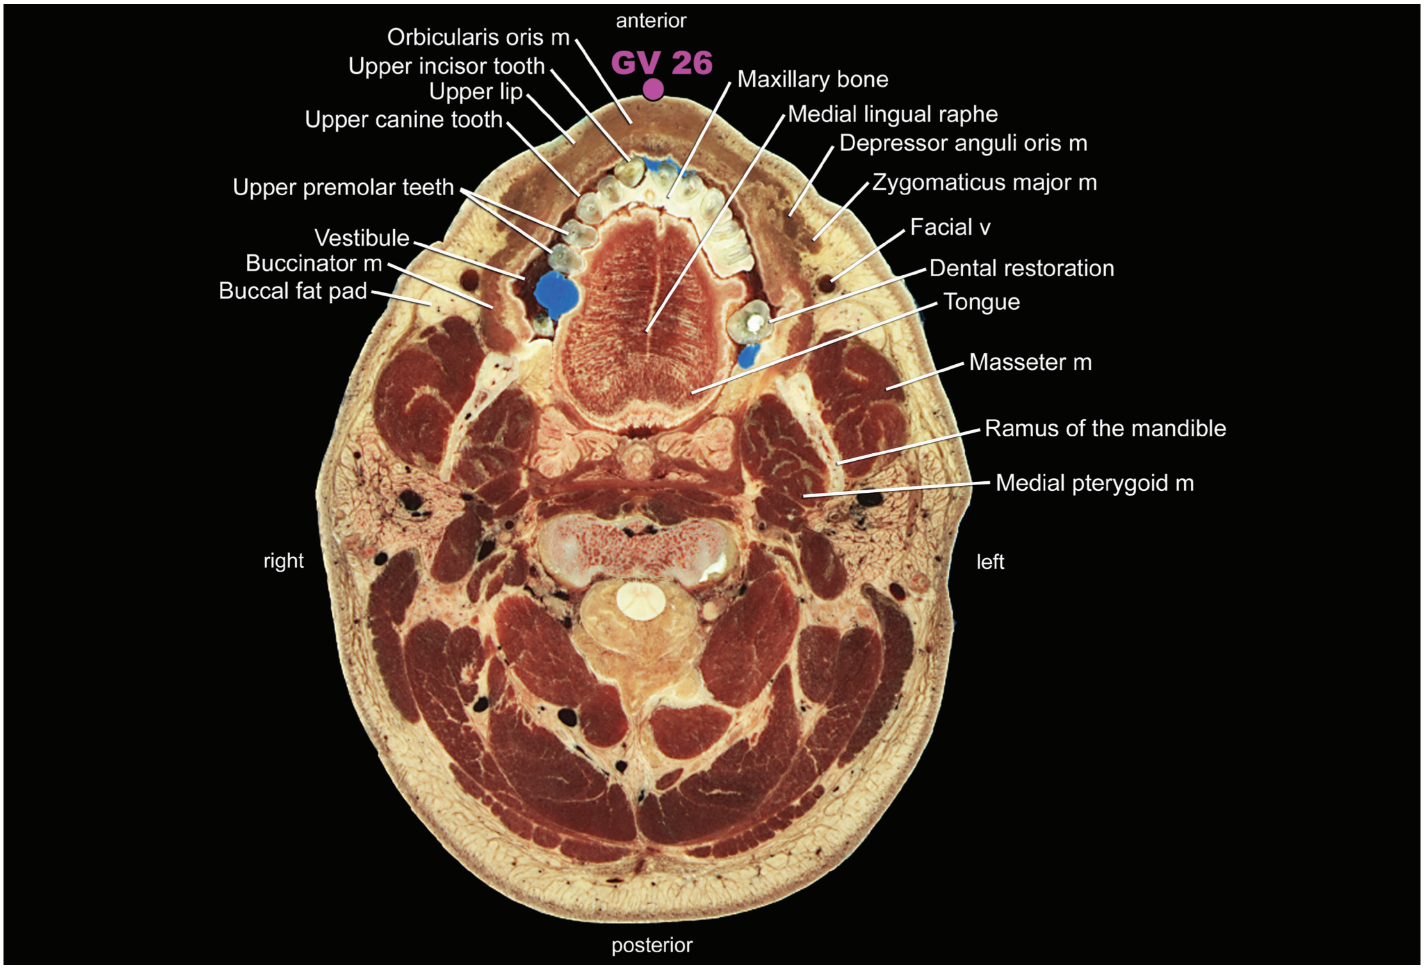

Figure 14-76. Perioral tissue at and around GV 26 contains a high density of somatosensory and sympathetic fibers. This accounts for the point's profound effects on autonomic function, brain activity, and the heart.

Sometimes, stimulation of the same acupuncture point under different clinical conditions can produce opposite responses.

The reason for this is that acupuncture works by neuromodulation, which may raise or flatten physiologic reactions, based on the direction needed for homeostasis. The latest functional brain imaging studies on acupuncture illustrate such modulatory neural and autonomic responses in various parts of the brain, including the limbic, paralimbic, and subcortical gray areas, as well as the cerebellum.[7]

Research literature attesting to the effectiveness of GV 26 in treating cardiovascular depression began appearing in the English language veterinary literature in the 1970's. Over the two decades, numerous papers documented the sympathomimetic effects of GV 26 in various species.[8,9,10,11,12,13] Further studies showed that pretreatment with either alpha or beta blockers inhibited the sympathomimetic effect.[14,15,16] Needling adjacent regions as "sham acupuncture" points failed to result in significant changes in cardiovascular function.[17] A report on GV 26 for resuscitation of neonatal kittens delivered by cesarean section demonstrated success following unproductive cardiopulmonary resuscitation attempts.[18]

Sympathomimetic effects of GV 26 in various species;[19,20,21,22,23,24,25,26] pre-treatment with either alpha or beta blockers inhibited the sympathomimetic effect.[27,28,29]

- Electroacupuncture on GV 26 in the early postoperative period may promote **hemodynamic stability** by attenuating plasma catecholamine fluctuations.[30]
- Needling GV 26 may be able to help ascertain whether **unconsciousness** is due to a psychogenic or organic origin.[31]
- Treatment of **traumatic brain injury** by means of strong stimulation at GV 26 and the twelve ting or jing-well points three times weekly may have helped a patient regain consciousness following craniotomy for right-side subdural hemorrhage.[40]
- Needling GV 26 in addition to conventional acupuncture points may preferentially activate the prefrontal cortex and improve cognitive executive capacity in patients with **vascular dementia.**[41]

GV 27

Dui Duan "Extremity of the Mouth"

On the midpoint of the upper lip where it meets the philtrum.

Muscles

- **Orbicularis oris muscle:** Serves as the first in the series of sphincters associated with digestive structures. Orbicularis oris muscle fibers encircle the mouth and reside within the lips. Active contraction causes the lips to pucker, although over time its effects on the skin may also cause wrinkles. The orbicularis oris muscle has been regarded as a simple sphincter, or circular muscle, like the orbicularis oculi. Now, some claim that it comprises four independent quadrants of muscles that together encircle the mouth. Orbicularis oris fibers intermix with those of surrounding muscles of facial expression that also insert onto the lips, such as the buccinator muscle. Additional intermingling muscles include the caninus, triangularis, quadratus labii superioris, zygomaticus, and quadratus labii inferioris, along with the nasolabilis, incisivus labii superioris, mentalis, and incisivus labii inferioris muscles.

Clinical Relevance: The aging perioral region is associated with upper lip lengthening and wrinkling.[1] As the orbicularis oris muscle thins, the subcutis thickens, and elastic as well as collagen fibers degenerate. Conceivably, treatment with laser therapy or other means of improving tissue health may forestall some of the consequences of advancing age on perioral appearance.

Facial nerve injury may impair the ability of an individual to close the mouth with the action of the orbicularis oris muscle. Neuromodulation applied to GV 27 may aid in restoring its function.

Cleft lip affects orbicularis oris muscle anatomy.[2] That is, with incomplete clefts, the intrinsic portion within the vermilion is interrupted without distortion while the extrinsic part, i.e., the portion outside of the vermilion, distorts vertically in relation to the degree of nasal deformity. Complete clefts cause the extrinsic part to deviate more significantly. These differences influence surgical repair (cheiloplasty) which requires reorienting orbicularis oris muscle fibers.

Nerves

- **Superior labial branches of infraorbital nerve (CN V$_2$):** Provides cutaneous sensation to the upper lip.
- **Buccal branches of facial nerve (CN VII):** The buccal branch of the facial nerve supplies the upper part of the orbicularis oris muscle and the inferior portion of the levator labii superioris muscle.

Clinical Relevance: GV 27 sends afferent stimulation through infraorbital nerve branches; it affects motor innervation of the orbicularis oris muscle through the buccal branch of the facial nerve. Injury to the buccal branches of the facial nerve warrants consideration of additional points such as ST 4 and CV 24.

Smoking and a countenance that includes chronic pursing of the lips may accentuate the appearance of wrinkles on the upper lip. For this condition, plastic surgeons seek to interrupt, rather than improve, facial nerve function in order to reduce muscle contraction and foster skin relaxation.[3]

"Beauty" Tip: The yoga posture known as "Lion Pose", or Simhasana, counters the chronic contraction of the orbicularis oris fibers associated with the formation of vertical wrinkles around the mouth and lips. It does so by stretching the skin and re-lengthening muscle as the mouth opens widely, like a lion issuing a loud and long roar.

Vessels

- **Anastomosis of the superior labial arteries:** The superior labial arteries branch from the facial artery and course mediad along the upper lip, anastomosing at GV 27. They supply the upper lip, nasal septum, and nasal alae. See Figure 14-75 B to view the relationship between the facial artery and the superior labial arteries.

Clinical Relevance: Knowledge of the arterial anatomy of the oronasal region is imperative for cosmetic and lip repair surgery.[4] Should mishaps occur, restoration of circulation by means of laser therapy, massage, and acupuncture at GV 27 and surrounding sites may hasten return of vascular supply.

Indications and Potential Point Combinations

- **Labial pain or swelling:** GV 27, ST 4.
- **Nasal obstruction:** GV 27, LI 20.
- **Facial nerve injury affecting the buccal branch:** GV 27, ST 4, CV 24.

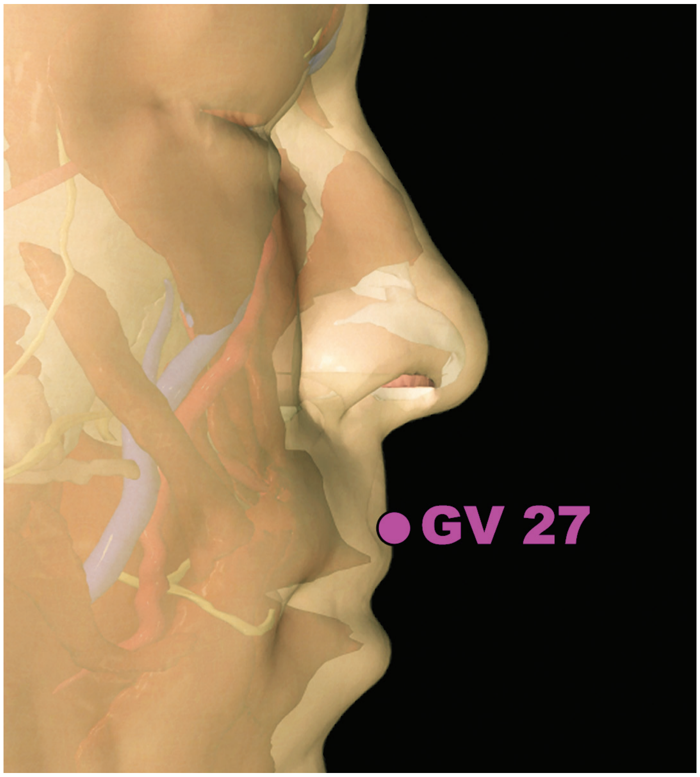

Figure 14-77A. GV 27, "Extremity of the Mouth", identifies the location where the philtrum meets the upper lip. When the mouth opens, GV 27 indicates highest point, or extremity, of the mouth.

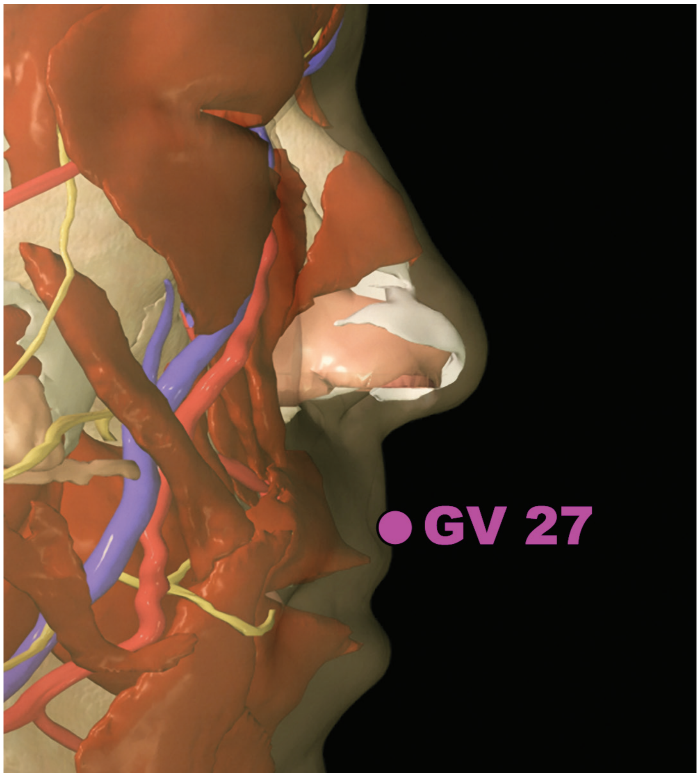

Figure 14-77B. Note how GV 27 points to the junction of the intrinsic and extrinsic parts of the orbicularis oris muscle deep to the lip and surrounding the mouth, respectively. Their different orientations, with the intrinsic part jutting out, suggest different functions. That is, the intrinsic part identifies more with pursing the lips for a kiss or pout, while the extrinsic part can close the mouth on its own, even if the lips relax.

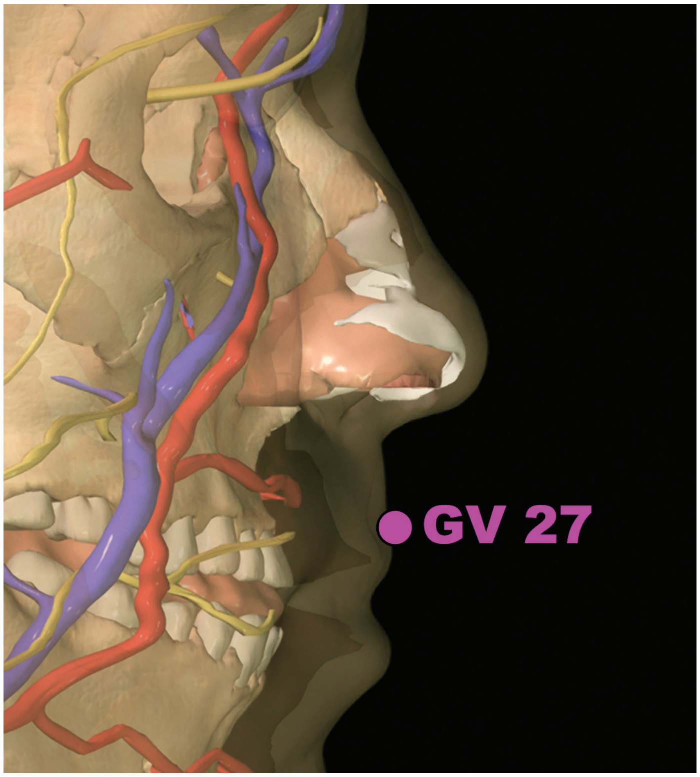

Figure 14-77C. This image highlights the relationship between the buccal branches of the facial nerve (overlying the teeth) and GV 27.

GV 28

Yin Jiao “Gum Intersection”

In the mouth, on the midsagittal plane, at the junction of the frenulum of the upper lip with the maxillary gingiva.

Connective Tissues

- **Labial frenulum:** During development, the frenulum, a free-edged fold of mucous membrane along the midline, guides development of structures of the oral cavity. Although they later recede and diminish in size, frenula help guide the positions of the baby teeth during childhood.

Clinical Relevance: Several frenula exist in the body; the term “frenulum” means “little bridle” in Latin. It refers to a small tissue fold that tethers more mobile structures to fixed locations. The mouth has three frenula: the frenulum linguae under the tongue, the frenulum labii inferioris inside the lower lip, and the frenulum labii superioris within the upper lip at GV 28. Trauma to the face and mouth may tear one or more frenula. Finding a torn frenulum in a patient may indicate physical abuse from violent assaults to the head.

Muscles

- **Orbicularis oris muscle:** Serves as the first in the series of sphincters associated with digestive structures. Orbicularis oris muscle fibers encircle the mouth and reside within as well as around the lips. Active contraction causes the lips to pucker, although over time its effects on the skin may also cause wrinkles. The orbicularis oris muscle has been regarded as a simple sphincter, or circular muscle, like the orbicularis oculi. Now, some claim that it comprises four independent quadrants of muscles that together encircle the mouth. Orbicularis oris fibers intermix with those of surrounding muscles of facial expression that also insert onto the lips, such as the buccinator muscle. Additional intermingling muscles include the caninus, triangularis, quadratus labii superioris, zygomaticus, and quadratus labii inferioris, along with the nasolabialis, incisivus labii superioris, mentalis, and incisivus labii inferioris muscles.
- **Depressor septi nasi muscle:** Constricts the nasal aperture by drawing the nasal septum downward and narrowing the nostril openings. Depressor fibers originate from the incisive fossa of the maxilla and insert onto the nasal septum and dorsal portion of the alar part of the nasalis muscle. This muscle sits between the mucous membrane of the lip and the orbicularis oris, as shown in Figure 14-82. Not all individuals have a depressor septi nasi muscle, and it is not clear if this individual had one or not. That said, if one is present, it is more directly accessible by means of an intraoral approach, starting at GV 28.

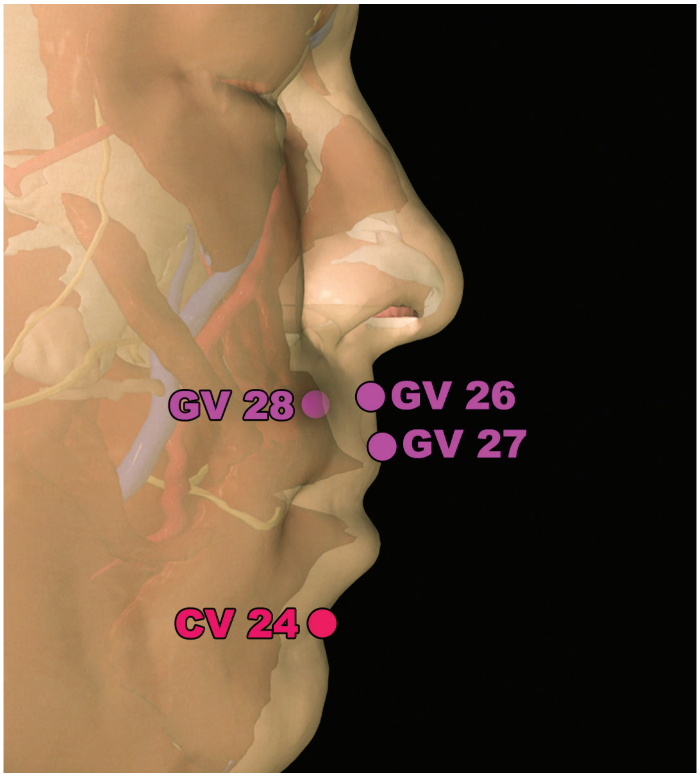
Clinical Relevance: The aging perioral region is associated with upper lip lengthening and wrinkling.[1] As the orbicularis oris muscle thins, the subcutis thickens, and elastic as well as collagen fibers degenerate. Conceivably, treatment with laser therapy or other means of improving tissue health may forestall some of the consequences of advancing age on perioral appearance.

“Beauty” Tip: For upper and lower lip wrinkles, one can push the lips forward with the tongue, thereby stretching a chronically contracted orbicularis oris muscle. The Lion Pose in yoga, described previously, also stretches orbicularis oris fibers.

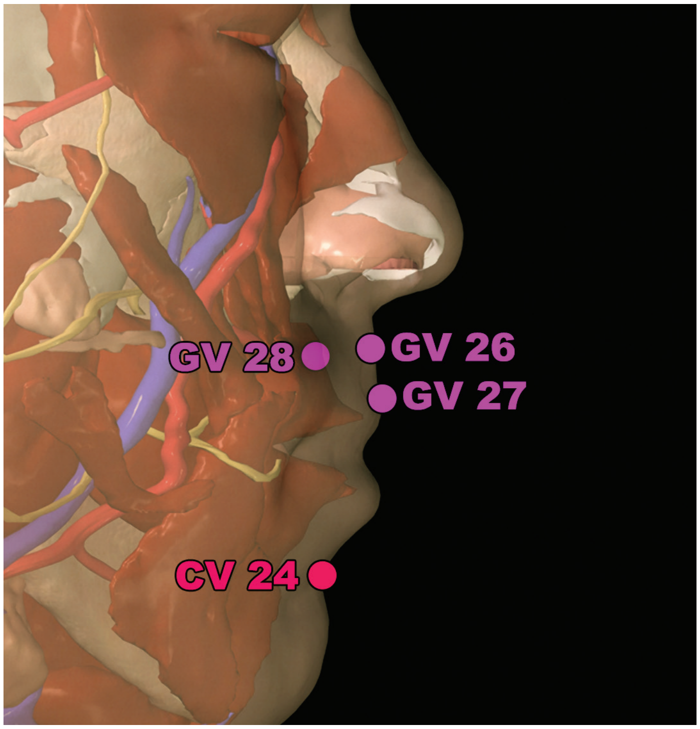
Facial nerve injury may impair the ability of an individual to close the mouth. Neuromodulation applied to GV 28 may aid in restoring function of the dorsal and ventral branches of the buccal branch of the facial nerve (see Figure 14-81).

Cleft lip directly upsets orbicularis oris muscle anatomy.[2] That is, with incomplete clefts, the intrinsic portion within the vermilion is interrupted without distortion while the extrinsic part, i.e., the portion outside of the vermilion, distorts vertically in relation to the degree of nasal deformity. Complete clefts cause the extrinsic part to deviate even more. These differences influence surgical repair of cleft lip (cheiloplasty), which requires, in part, reorienting orbicularis oris muscle fibers to allow oral closure.

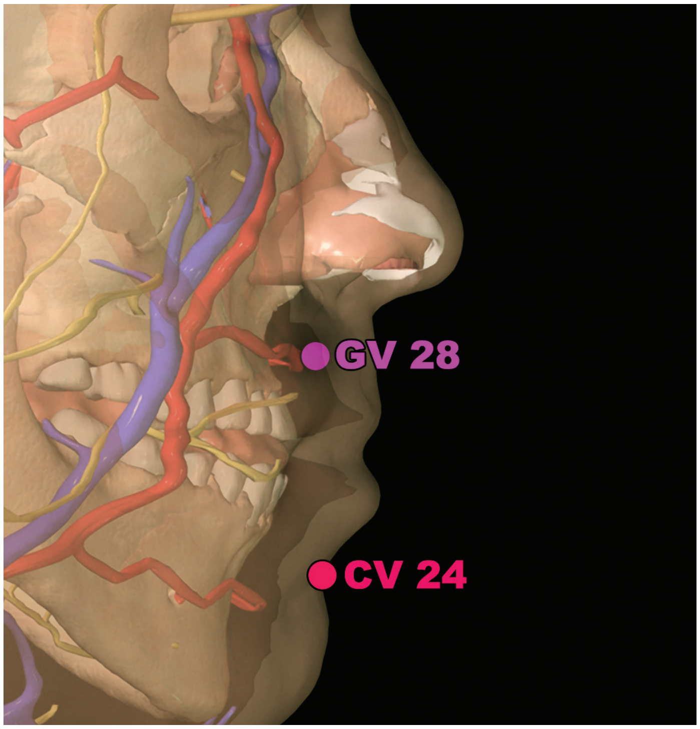
“Smiling deformity” or rhinogingivolabial syndrome is a condition in which the tip of the nose appears to lengthen during smiling or talking as a result of excessive depressor septi nasi muscle contraction.[3,4] An overactive the depressor muscle can make the upper lip seem shortened and reveal an unattractive amount of maxillary gingival tissue.[5,6] A surgical treatment for this problem involves septoplasty (to correct the septum if deviated), dynamic rhinoplasty (i.e., muscular treatment of the nasal tip and upper lip), rhinosculpture (addressing aesthetics of the nasal root, dorsum, and tip), and turbinectomy (involving partial bone-mucous resection in cases of hypertrophied turbinates). Botulinum toxin may obviate the need for surgery when injected into the depressor septi nasi muscle.[7] Conceivably, release of tension in the depressor septi nasi muscle with acupuncture and related techniques at GV 28 and GV 26 could also improve upper lip appearance by relaxing the depressor muscle and thereby allowing the upper lip to lengthen.



Figures 14-78. The GV channel ends at the top of the mouth; the CV channel ends below the mouth. This image shows how GV 28 resides inside the lip, at about the same level as GV 26.



Figures 14-79. GV 28 affords ready access to the depressor septi nasi muscle as it sits between the orbicularis oris muscle and mucosal lining of the upper lip.



Figures 14-80. GV 28 relates to the superior labial artery, a branch of the facial artery, in an analogous way that CV 24 relates to the inferior labial artery, another branch of the facial artery.

Buccal br, facial n (CN VII) ventral br
CV 24
Inferior alveolar a, v
Inferior alveolar n (CN V3)

Figures 14-81. This image reveals the proximity of GV 28 and CV 24 to the maxillary and mandibular teeth, respectively. The semi-transparent bones reveal the inferior alveolar artery, vein, and nerve within the mandibular canal. While the buccal branches of the facial nerve appear to relate to the teeth, they mainly do so geographically, not functionally. That is, these nerve branches supply motor innervation to the orbicularis oris and related muscles of facial expression. It is the trigeminal nerve, with branches from its maxillary and mandibular divisions that supplies sensation to the upper and lower dental arcades, respectively. Specifically, GV 28 relates to the infraorbital nerve (CN V_2), which innervates the upper teeth while the inferior alveolar nerve (CN V_3) supplies sensation to the lower teeth.

Nerves

- **Superior labial branches of infraorbital nerve (CN V_2):** Provides cutaneous sensation to the upper lip.
- **Buccal branches of facial nerve (CN VII):** The buccal branch of the facial nerve supplies the upper part of the orbicularis oris muscle and the inferior portion of the levator labii superioris muscle.

Clinical Relevance: Stimulation of GV 28 sends afferent stimulation through infraorbital nerve branches; it affects motor innervation of the orbicularis oris muscle by neuromodulating the buccal branch of the facial nerve. Injury to the buccal branches of the facial nerve warrants consideration of additional points such as ST 4, CV 24, and GV 27.

Smoking and adopting a pursed-lip countenance over time may accentuate the appearance of wrinkles on the upper lip. For this condition, plastic surgeons seek to diminish local facial nerve function in order to reduce muscle contraction and foster skin relaxation.[8]

Vessels

- **Anastomosis of the superior labial arteries:** Arising from the facial artery near the corner of the mouth, the superior labial arteries run along the upper lip in a medial direction, to supply the upper lip, the nasal septum, and the nasal alae. Their anastomoses with each other and with the inferior labial arteries form an arterial ring around the oral cavity.

Clinical Relevance: Knowledge of the arterial anatomy of the oronasal region is imperative for successful cosmetic and lip repair surgery.[9] Should mishaps occur, restoration of circulation by means of laser therapy, massage, and acupuncture at GV 28

and surrounding sites may foster circulatory recovery.

Indications and Potential Point Combinations

- **Gingivitis:** GV 28, ST 24.
- **Tooth pain:** GV 28, LI 4.
- **"Smiling deformity" with shortened upper lip due to depressor septi nasi muscle hypercontraction:** Massage, laser therapy to GV 28 and GV 26 down to GV 27.

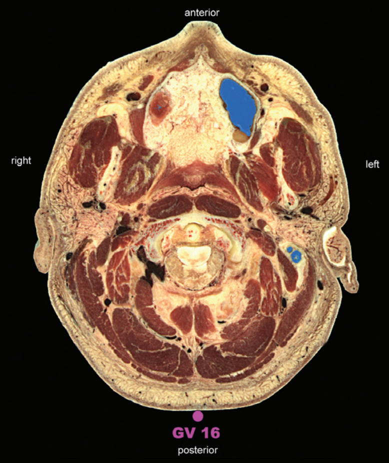
Interactive Medical Acupuncture Anataomy is a clear and practical guide to the practice of medical acupuncture focused on the interrelationship of structure and function.

The 1,051 images in this text delineate the relationships of acupuncture points with nearby anatomy that help to explain the physiological effects of point activation. This highly detailed investigation of the neuroanatomical basis and evidential support of acupuncture deeply informs its clinical application, making this work a "must have" for your medical practice library.



- An anatomically precise presentation of acupuncture points and channels
- Complete, 3-dimensional, computer generated images of the human body
- Permits visualization of the underlying anatomical structures that acupuncture needles stimulate
- Provides the critical information needed for safer and more productive acupuncture practice
- Thousands of references supply much-needed evidential support of acupuncture science and practice
- Provides scientific validation for the effects of acupuncture on visceral, immune, circulatory and other bodily functions
- National Library of Medicine Visible Human Project images provided on the DVD provide 3-dimensional, rotatable, dissectible, Quick Time Virtual Reality images for identification of acupuncture points and their neural and vascular relationships.
